An Address

ON THE

EARLY SYMPTOMS OF DISEASE, WITH SPECIAL REFERENCE TO THE EYE.

Delivered at the Opening of a Post-graduate Course at the James Mackenzie Institute for Clinical Research, St. Andrews,

BY A. MAITLAND RAMSAY, M.D., LL.D., F.R.F.P.S. GLASG.,

HON. DIRECTOR OF THE INSTITUTE; CONSULTANT OPHTHALMIC SURGEON TO THE ROYAL INFIRMARY, GLASGOW.

THE laboratory has played such a predominating part in the undergraduate education of the doctor of the present day that there is a danger that he has been taught to rely too much on instruments of precision and bacteriological and biochemical equipment. An exaggerated importance has come to be attached to all means of that kind, and a subordinate position has been given to the information gained by careful observation of symptoms and by a wise consideration of the general condition of the patient. Nature is constantly performing experiments in the laboratory of the human body, and although the results of such experiments are far too delicate to be measured by test-tube or balance, they are always revealed by the occurrence of symptoms. In order to learn how to interpret symptoms, the mind must be trained to become familiar with the natural history of disease. It is not possible to offer a prognosis from a series of barren facts. It is necessary that a general truth be extracted from the observation of a multitude of isolated symptoms, which must be interpreted before their meaning can be understood.

SYMPTOMS: THEIR CAUSATION AND SIGNIFICANCE.

The causation and significance of symptoms must be explained, in the first instance, by the physiologist, but he must work in close collaboration with the clinician, because many of the truths he endeavours to teach can be demonstrated more clearly at the bedside than in the laboratory.[1] A hypothesis based on clinical evidence may be proved to be wrong, but if it has served as a guide it may, in the long run, lead to important results, and pave the way to the discovery of true facts. Much purely laboratory investigation has failed for want of clinical direction.

Symptoms present a new interest when an objective cause is discovered to explain their occurrence. In the great majority of cases the earliest symptoms of disease are produced by reflex action, which in all probability takes its origin primarily in the capillary system.[2] The rôle played by the capillaries is distinct from that of the heart and blood-vessels.[3] The capillaries are not simply tubes through which blood flows. The capillary wall is in all probability formed out of the tissue in which it lies, and is not merely an attenuated extension of the vascular system. The cells of an organ have a direct influence upon the capillaries, and much depends upon the manner in which they react to the call of the tissues for nourishment—to the "hunger" of the tissues, as the late Clifford Allbutt used to say. The capillaries are, however, very susceptible to every morbid influence. They are at once distended by blood vitiated by bacterial or biochemical toxins.[4] Such a change in the capillaries can be proved by experiment, as, for example, when a toxic substance is injected intravenously in a living animal. The congested state of the capillaries causes slowing of the circulation, which is always accompanied by impairment of the function of the organ concerned. It may be stated as an axiom that the distribution of capillaries is always greater in proportion to the functional activity of the tissue in which they lie, consequently the functional activity of every organ of the body depends upon the rate at which blood circulates through its capillaries. Take the kidney in general toxæmia, for example. The toxins in the blood cause great dilatation of the capillaries of the glomeruli, and in proportion to the slowing down of the local circulation the excretion of urine diminishes until it may be wholly suppressed. When therapeutic measures are taken to speed up the circulation in the glomeruli, the output of urine increases immediately and diuresis continues until the reaction of the uriniferous tubules to their capillary supply is restored to the normal condition.

What can be easily demonstrated by experiment in the kidney can be seen in the eye by means of the ophthalmoscope. The objective examination of every part of the eye has reached a degree of perfection which has no parallel in any other part of the body. A study of the living eye, therefore, enables an observer to see what is going on, and as the basis of all vital activity is either chemical or electrical, it is reasonable to assume that what occurs in the eye will, under like conditions, also occur in other parts of the body where the phenomena are hidden from view. There is a unification of physiological and pathological processes. As disease is simply a perversion of natural processes, symptoms of disturbance of function must inevitably precede any signs of damage to structure sufficiently gross to be detected by any instrument of precision or by chemical or electrical tests. It is a matter of common experience in the study of the eye that in certain cases subjective examination affords earlier and more accurate information than can be got by an ophthalmoscopic examination. In what follows I wish to draw attention to the value of the information that is to be got from a careful study of those symptoms associated with disorder of the visual function.

DISORDERED FUNCTION IN THE EYE.

From the point of view of general physiology the characteristic feature of vision is the reception of light by the retina.[5] The rods and cones must be regarded as the functioning unit of the eye in the same way as the muscle-fibre is the functioning unit in the heart and the glomerulus in the kidney. That is important, because the first step in the study of derangement of function of any organ is to determine its functioning unit, and of equal importance with the functioning unit itself is the study of its capillary supply. The unit together with its capillaries are the organ in miniature, and functional activity depends upon the manner in which these two constituents react upon one another. Whenever the capillaries of the choroid or of the retina are congested the light sense becomes impaired. The rods and cones are supplied by the blood-vessels of the choroid—the choriocapillaris—while the inner layers of the retina, including the ganglion-cells and the nerve-fibres, are nourished by the capillaries associated with the retinal blood-vessels. The feeblest light capable of causing sensation is known as the light minimum. It is always disturbed in diseases which interfere with the circulation in the choriocapillaris and thereby starve the rods and cones of the retina. If, on the other hand, the capillaries in association with the retinal blood-vessels are disturbed, the ganglion-cells and nerve-fibres suffer, and a greater contrast in illumination is necessary before a difference can be appreciated. The smallest increase in brilliancy of one of two lights is spoken of as light difference. Increase in light difference implies, therefore, that the conducting apparatus of vision—ganglion-cells and nerve-fibres—is affected, whereas increase in light minimum is the earliest symptom that the receiving apparatus of vision—layer of rods and cones—is at fault. It is true that the eye differs from other sensory organs in that there is not merely a threshold of sensibility, but also a variation in the threshold according to any change occurring in the surrounding illumination. That special function is spoken of as adaptation,[6] and the eye possesses a wide range of adaptation for light and darkness, corresponding to the daily variation in the intensity of the light. In fact, the human eye is capable of adapting itself to almost any degree of illumination; consequently,

649698

results of the examination of the light sense will vary according to the conditions in which the test has been applied. Moreover, the tests for light minimum and light difference are not interchangeable, because, as has already been pointed out, each has its own special value and diagnostic significance. A study of the light sense, however, has more than an academic interest; it has a real clinical value. For laboratory investigations many different photometers have been devised, but for clinical examinations Percival's discs[7] and Young's threshold tests[8] are satisfactory and convenient. By their help the examiner can quickly discover increase either in light minimum or in light difference. An increase in light minimum denotes that there is a lesion in the layer of rods and cones or some insufficiency of the visual purple, and is always present in deep hæmorrhage in the retina, and in all inflammations either of the retina or of the choroid in which the rods and cones are implicated. Increase of the light difference, on the other hand, denotes that there is a lesion of the superficial layers of the retina. It is diagnostic of toxic amblyopia, or of inflammation or atrophy of the optic nerve. It often happens that an intelligent patient suffering from failing sight so describes the onset of his symptoms that the examiner at once gets a clue to the diagnosis. Let me give an instance:—

A sailor, who was suffering from advanced atrophy of both optic nerves, told me that the first thing that made him fear there was something wrong with his sight was the discovery that his companions on the watch were able to pick up land more quickly than he could, whereas he knew that formerly he was able to distinguish land a considerable time before anyone else on the ship. He was all the more impressed by this disability because, even when he was so far behind his fellows in distinguishing land, he could see a light at night as well as ever, and frequently before the officer and the others on the watch. In this case it was obviously an increase in light difference that was the first symptom of disease, and its prompt recognition might have enabled a diagnosis to have been made, and appropriate treatment to have been begun, while yet there was a chance of cure, instead of waiting until the pathognomonic ophthalmoscopic changes of optic atrophy had become visible. By that time the disease had reached a stage when cure was impossible, the fibres of the optic nerve having become atrophied as a result of the obliteration of their capillaries.

An increase in light minimum is usually accompanied by colour-blindness for blue, small dark blue objects, for example cornflowers growing in a field, are not seen to be blue but appear to be quite black. I will give an example of this:—

A milliner consulted me because she thought her sight was failing rapidly. There was, however, no diminution in the visual acuity when tested with the ordinary types, but she said that although she was able to see fairly well in a bright light, she was sure that she was having more difficulty than formerly in seeing to work in the evening or by artificial light. Moreover, she always considered that her colour sense was perfect, but of late she had been making serious mistakes over shades of blue, and when tested it was discovered that, whereas she had no difficulty in distinguishing red or green, there was a definite central scotoma for blue. The eyes were irritable, the pupils contracted, and the fundus oculi congested. In this case the discovery of the increase of light minimum and the colour-blindness for blue were the most important factors in diagnosis. Both are well-recognised symptoms of congestion of the choriocapillaris, and treatment prescribed with the object of reducing that congestion restored sight to normal in less than a month.

GLAUCOMA.

The chief interest in such a case arises from the fact that increase in light minimum is the earliest symptom of glaucoma. The patient usually has to change his reading spectacles repeatedly at very short intervals. He may say also that now and again he suffers from attacks of transient loss of vision, and that more or less constantly he sees coloured halos like a rainbow round gas, lamp, or candle flame. Such symptoms are almost certainly premonitory of glaucoma. The patient probably mentions them casually, but if they be appraised at their proper value means will at once be taken to check the disease before increase in intraocular tension has become permanently established. It is only after the optic nerve becomes injured by increase in intraocular pressure that the light difference becomes affected. That observation has an important bearing on the pathogenesis and the treatment of the disease. It proves the existence of a morbid process affecting the choriocapillaris prior to the occurrence of blocking of the filtration spaces at the corneo-iridic angle. At the onset of glaucoma it is very unlikely that an eye can be examined microscopically, hence the importance of the symptom. It is only after the disease is thoroughly established that an eye may have to be enucleated. In such circumstances the most painstaking laboratory examination can only reveal end-results. It can throw no light on the beginnings of the disease. Moreover, although decompression operations by reducing intraocular tension can in many instances stay the progress of the disease, yet, as they do not remove the cause, they cannot be regarded as a cure for glaucoma. In some cases, as is well known, the disease continues to advance in spite of the best surgical skill, and in the great majority appropriate constitutional treatment is necessary both before and after operation.

Difficulty in seeing in a dim light may be a patient's chief complaint. He says that he suffers no inconvenience in ordinary daylight, but as soon as twilight sets in he sees so badly that to all intents and purposes he is blind. This form of night blindness is a sure indication that pathological changes are in progress in the bacillary layer of the retina accompanied by failure in the regeneration of the visual purple. That is to say, that the constructive metabolism of visual purple cannot keep pace with its consumption. The sympton is pathognomonic of that form of degeneration of the retina known as retinitis pigmentosa, which, in its typical form, gives such a characteristic picture on ophthalmoscopic examination. In some cases of night blindness, however, the ophthalmoscope reveals nothing abnormal, and in these circumstances the recognition of the symptom is of the greatest value. The disease may be hereditary and congenital, and is often discovered accidentally. The parents never suspect that their child's sight is affected until they notice that if it be out of doors after sunset it becomes so blind and helpless that it may have to be carried home. Night blindness sometimes occurs in adults as a result of malnutrition, over-fatigue, or dazzling of the eyes from exposure to bright sunlight. Many such cases were seen among the soldiers engaged in the Great War. Diet may be ample in quantity, but if it be deficient in essential vitamins sight is rapidly and seriously affected.

ABNORMALITIES OF VISION.

There is another group of cases in which the patients see best in a dull light and in which an outstanding symptom is an increase in light difference. Let me give an example.

A patient, usually from 40 to 60 years of age, may say that for a considerable period his sight has been misty—so much so, indeed, that he has for several weeks experienced difficulty in reading ordinary type and that during the past few days it has suddenly become so much worse that he is quite unable to read or write. He may also complain that he cannot even recognise friends when he meets them in the street and may add that he is shocked at the appearance of his friends; they look so ill and "corpse-like," all healthy colour being absent from their face. He also may say that he sees best in a dull light; that in bright light he is easily dazzled; a whitish or yellowish mist rises like a cloud in front of the eye and prevents him from seeing clearly. Towards sunset however, this sense of dazzling disappears, and in consequence he can always see best in the evening. He may also complain spontaneously that his colour sense is disordered, and testing will show that while he has no difficulty in distinguishing red and green in the peripheral parts of the field of vision, he is unable to perceive these colours in the central area. Red appears brown and green appears white. As the

disease progresses those colours assume a metallic lustre, red is said to "glitter like gold" and green to appear "like silver." In some cases blue is a strikingly predominant colour—a bunch of sweet peas is thought to be made up of blooms of different shades of blue. I remember an artist whose sight was beginning to fail. He had been famous for the brilliant colouring of his pictures, but at this period his friends could not understand how it was that the reds and the greens were completely overshadowed by a predominance of blue in everything he painted. It is interesting that this peculiar colour defect is very often associated with the presence of oxalate of lime crystals in the urine—one of the most reliable signs of disordered metabolism.[9]

The defect is in the centre of the field of vision, and any object in the line of fixation is a blank, but the patient cannot be said to be blind, because he can see on all sides of the centre of the visual field. Such a blank is called a scotoma, and as the patient is not conscious of anything intervening between him and the object looked at it is said to be negative. When, on the other hand, the scotoma is positive, the patient complains that a black spot covers every object he looks at directly, and if he gazes at the sky or a white wall, he sees a dark patch straight in front of him. This distinction between a negative and a positive scotoma is of considerable clinical value, because the former always implies a lesion of the nervous system, whereas the latter indicates that the retinal elements subjacent to the lesion are intact. If, for example, a patient on awakening from sleep discovers that he sees imperfectly with one eye, and a negative scotoma is discovered, he is suffering from a lesion of the optic nerve; whereas if a positive scotoma be present, the lesion must be situated in front of an intact layer of rods and cones, and is in all probability a hæmorrhage. The patient sees the blood-clot in his own eye.

Defect of sight in these circumstances at once suggests that the trouble is due to excessive indulgence in tobacco or alcohol, or both; and careful examination will in most instances confirm that opinion. A central negative scotoma, however, is not always pathognomonic of toxic amblyopia, for a similar blank in the centre of the field of vision occurs in disseminated sclerosis, in hereditary optic atrophy, and in inflammation of the air sinuses adjacent to the orbit when there is pressure on the optic nerve in the neighbourhood of the optic foramen. In those conditions, however, one eye only is implicated or one eye is affected much in advance of the other, and the more serious cases are accompanied by a pronounced feeling of exhaustion, while in toxic amblyopia the dimness of vision is, as a rule, equally pronounced in both eyes, and the patients are usually strong and healthy. In every case the diagnosis must be made from a careful examination of symptoms rather than from any characteristic ophthalmoscopic appearances. Indeed, in toxic amblyopia the contrast between the gravity of the symptoms and the absence of any distinctive lesion that can be discovered with the ophthalmoscope is one of the most striking features.

OTHER DEFECTS IN PERCEPTION.

Occasionally a patient complains that every object looked at is altered in size, or is thrown out of proportion and twisted. This symptom is known as metamorphopsia, and is often of very serious import. The distortion may, of course, be due to errors in the optical construction of the eye, but is much more likely to be induced by pathological changes in the retina itself, and is then significant of grave disorder of vision and usually means inflammation of the choroid. In this case it is caused by some change in the relative position of the rods and cones, and is most serious when the macular region is implicated. In some instances, where the percipient elements of the retina are separated by exudation, objects appear too small (micropsia); in others, where the percipient elements are crowded together owing to cicatricial alterations, they seem too large (macropsia); and in still others they assume very irregular shapes. It is sometimes difficult to detect with the ophthalmoscope the changes that give rise to the metamorphopsia, hence the value of the symptom in leading to a correct diagnosis.

That is in marked contrast to the condition in which symptoms are due to a change in the refractive media, the functioning unit remaining intact. It is very significant when a patient who has required to wear glasses for reading finds that he sees better without them. He is generally much pleased at the discovery, and says he has got his "second sight." If, however, his vision be tested, it will be found that he is now myopic, and requires concave glasses to enable him to see in the distance. Very probably he may say also that when he looks at the moon it appears doubled or quadrupled—monocular polyopia. Such a combination of symptoms is certainly due to changes taking place in the lens, and is in most instances premonitory of cataract. It is very important that the disease be recognised at such an early stage, because this allows of careful ophthalmoscopic examination of the fundus, and the detection of any pathological changes in the choroid or retina, at a time when the lens is still sufficiently transparent to permit these structures to be seen. Transient changes in refraction, whether in the direction of myopia or hypermetropia or an unusually early onset of presbyopia, should never be passed over without careful consideration. In such circumstances, in addition to the use of the ophthalmoscope, the urine ought always to be examined, because that derangement of the visual function may lead to the early diagnosis of glycosuria.[10]

Patients frequently complain of muscæ volitantes, but though these often give rise to much annoyance they do not indicate the existence of organic disease unless floating bodies be seen on ophthalmoscopic examination. They point, at the most, to a condition of retinal hyperæsthesia, determined, in all likelihood, by prolonged application of the eyes to close work. In these circumstances the refraction ought to be carefully tested, the urine examined for oxalate of lime or uric acid crystals, and the patient discouraged from looking for the muscæ, as these are only too prone to reappear whenever attention is directed to them. It is, however, sometimes not easy to draw the line between what may be regarded as physiological and what is pathological. A careful ophthalmoscopic examination is therefore necessary in every case, more especially if the patient be short-sighted, for in these circumstances opacities in the lens, or floating bodies, or hæmorrhages, may be detected in the vitreous humour, and be premonitory of detachment of the retina. In simple myopia there is no disturbance of the light sense, consequently if in an individual case increase in light minimum be detected it is evidence of some interference with the nutrition of the bacillary layer of the retina and adds to the gravity of the prognosis, even in cases in which the ophthalmoscope reveals no structural damage in the fundus. Sparks and flashes of light are often due to disturbance of the circulation in the retina or choroid, and in many instances they are the first symptoms of disease. In inflammation of the choroid the sensation of dazzling may be very pronounced, and be accompanied by flashes of light of various colours. At other times complaint is made of constant showers of golden dust, or of large numbers of black specks floating in front of the eyes, of stationary spots of larger size, or of a veil which seems to hang in front of the line of vision. In those circumstances it is the least refracted end of the spectrum that causes most trouble, and the patient experiences great relief by wearing peacock-blue glasses which cut off the red rays.

THE STUDY OF SYMPTOMS.

It is often said that a straw shows the direction from which the wind is blowing, but if the observer is not sure of his own orientation he learns nothing

from watching the movements of the straw until he consults a compass. Accurate knowledge of clinical physiology is the physician's compass, and if he can read it correctly he will never go far astray. A complaint of discomfort is usually all that is revealed of the beginnings of disease. In the case of the eye these subjective sensations are referred to the organ itself, but in the majority of instances—for example, those associated with the heart or the kidney[10]—they are referred to some other part of the body. Such symptoms are usually slight and transient and on that account are easily overlooked and forgotten, but when properly interpreted they convey much information at a time when to possess it redounds not only to the benefit of the patient, but also to the credit of the physician. The illustrations I have given have been drawn from ophthalmology, because my own clinical experience has been gained by a study of diseases of the eye. It is, however, essential to bridge over the gap between narrow specialism and general medicine, because no progress can be made until it is recognised that the principles of general physiology are sufficiently broad and deep to include every organ of the body. To emphasise specialism is a retrograde step. It is always the same physiological and pathological processes that are at work. Peculiarities of anatomical structure are the cause of many of the signs and symptoms in different organs, and complicate a problem, which becomes greatly simplified when attention is focused upon the individual functioning unit and its capillaries. The study of symptoms, which I have tried to prove to be of pre-eminent assistance in connexion with the eye, is of equal value in the study of disorder in other organs of the body. Many family doctors, blessed with a retentive memory well stored with the results of a long clinical experience, possess a marvellous knowledge of the symptomatology of disease, but such knowledge, as a rule, dies with its possessor. It has not been formulated in such a way that others can make use of it after he dies. It ought, however, to be the bounden duty of every general practitioner not only to learn for himself, but also to add something to the general store of medical information. The Clinical Institute has been founded in order to try to remedy this defect, and one of its most important functions is not only to observe, record, and classify symptoms, but also to determine their true physiological foundation in order that their mechanism may be explained and their prognostic value properly assessed. Far from being in conflict with knowledge gleaned from other sources, symptomatology ought to supplement that knowledge and throw fresh light on many physiological and pathological problems. Failures at the bedside may often worry and disappoint the clinician and tempt him to appeal to the laboratory worker for a speedy solution of his difficulties. The laboratory, however, can give no short cut to diagnosis; laboratory methods and clinical methods must be studied side by side.

EXTENSIONS AT HEREFORD HOSPITAL.—A special meeting attended by over 100 governors of the Herefordshire General Hospital was held recently to consider proposals of the Board of Management to carry out extensive building operations and extensions so as to increase the accommodation to 160 beds and provide maternity and other wards, a private nursing home, and administration offices. The estimated cost is £72,000, and the motion approving of the scheme for 160 beds was carried only by a narrow majority.

A CASE OF
JUVENILE GENERAL PARALYSIS
SUCCESSFULLY TREATED BY MALARIA AND INTRAVENOUS AND INTRATHECAL INJECTIONS.

BY DAVID NABARRO, M.D., B.Sc., F.R.C.P. LOND.,

DIRECTOR OF THE PATHOLOGICAL DEPARTMENT, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON.

UNTIL the introduction of the malarial treatment of general paralysis by J. Wagner-Jauregg, the prognosis of this disease was hopeless, and the patients, after an illness of variable duration, during which one or more remissions might occur, inevitably succumbed. Combined treatment by malaria and antisyphilitic remedies has improved the outlook so much that we do not now regard the disease as incurable, and many patients have been restored to a life of usefulness. It is too early to say definitely whether they have been permanently cured, but I have one patient, whom I treated in conjunction with Sir James Purves-Stewart by the method advocated by him,[1] who has been clinically well for two and a half years. His blood and spinal fluid have been serologically negative for two years, after having been very strongly Wassermann-positive, with the spinal fluid typically paretic in other respects.

Hitherto all records of successful treatment of general paralysis in the literature have referred to adults, and, so far as I can ascertain, there is no recorded case of juvenile general paralysis having been successfully treated either by malaria or by any other means. It is of interest, therefore, to put on record this case of general paralysis in a child who was admitted to hospital apparently a hopeless lunatic and who has recently been discharged to a convalescent home apparently healthy. At the risk of being thought prolix, I have deemed it advisable to go somewhat minutely into the details of the clinical condition and of the treatment employed. My reasons are, first, that the case is historically interesting, because it is the first of its kind to be put on record; secondly, that I have already received requests from several medical superintendents of mental institutions asking me for details of the malarial and other lines of treatment adopted; and thirdly, that it illustrates how prolonged the treatment may have to be before any obvious improvement can be detected in the patient's condition.

History of the Case.

The history of the case is as follows:—

A girl, aged 6 years, was admitted to the Hospital for Sick Children, Great Ormond-street, on July 30th, 1925, under the care of Dr. Robert Hutchison, suffering from "mental disorder." The account as given by the parents was that the child was quite well and mentally normal up to three weeks before admission. She was late in coming home from school one evening, having apparently lost her way and taken five hours over a ten-minute walk. Afterwards her behaviour was strange. She cried and moaned for no apparent reason, she was troublesome and indeed became so naughty that the authorities would not keep her at school. She seemed dazed and made senseless remarks; she could not remember words, but her articulation is said to have been normal. She complained of headaches, but there was no trouble with vision or any other sense organ. Although it would appear from the account given by the parents that the onset of the mental trouble was more or less sudden, the school mistress stated that already, when the patient first attended school in February, 1925—that is, about five months before admission to hospital—she showed signs of abnormal mentality. She was listless and apathetic at times restless and inconsequent in her behaviour. On one occasion she is said to have had a "very unusual screaming fit" when she was brought into school, and towards the end of her stay at the school she took to slapping the other children. The mistress further adds that sometimes she could not give an answer to a question but just repeated the question itself, and she also mentions that th

[1] Brit. Med. Jour., 1924, i., 508.

child was unable to concentrate. There was very little to note in the earlier history; there were no infantile symptoms of syphilis, and according to the mother's account the child was very bright mentally and was able to go on errands for her and bring back the correct change.

Family History.—The parents were married in 1917. There is a history of one miscarriage at three months before the birth of the patient, and another, also at three months, in 1925. The father gives no syphilitic history, and his Wassermann in 1925 was quite negative. The mother likewise gives no syphilitic history, and her Wassermann in 1925 was practically negative (1, 0, 0, 0). Her Kahn test, however, was strongly positive.

Condition on Admission.

The child was physically well-nourished and healthy looking, but was sullen and quiet, and appeared to be unable to understand what was said to her. She was very dirty in her habits. About a week after admission she became very noisy and destructive and had attacks of violent temper, during which she tore up all her bed-clothes, in spite of the fact that she was strapped in her cot with fairly strong webbing and that her hands were encased in stockinged gloves. In one week she managed to tear up four sheets, two blankets, and two counterpanes, and broke four plates and three mugs.

Her speech was very indistinct, and on account of her mental condition she was extremely difficult to examine. The heart and lungs appeared normal; it was impossible to make any adequate examination of her central nervous system, as she was so resistant and demented. Vision appeared to be normal, and the pupils reacted to light and accommodation, but I may mention here that while the patient was under an anæsthetic on one occasion the fundus of the eyes was examined and typical syphilitic choroido-retinitis found to be present. There was no nystagmus. The knee-jerk and abdominal reflexes were present and the plantar reflex was flexor. Mentally the child was like an adult general paralytic—at times smiling fatuously and making meaningless noises, at other times crying and turning away from anyone near her and resisting any examination. She appeared to be suffering from headache, as she frequently put her hands up to her head and screamed. She was unable to feed herself, and although she improved slightly under the ward discipline, she was never taught to be clean and was always very noisy.

The day after admission the blood Wassermann was very strongly positive, and the case was diagnosed as probably one of juvenile general paralysis; this diagnosis was confirmed by the investigation of the cerebro-spinal fluid which was made on August 10th, with the result shown in the table. The Wassermann reaction was strongly positive, the colloidal gold curve and the other changes in the spinal fluid typical of G.P.I. I accordingly suggested to Dr. Hutchison that we might try treating the patient by cistern puncture and the injection of salvarsanised serum. From the summary of the treatment which is given later it will be seen that the first course of cisternal injections was given between August 18th and Nov. 4th, 1925. For this purpose 0·2 g. of novarsenobillon was given intravenously, and half to one hour later the patient was bled to the extent of 20–25 c.cm. The blood was allowed to clot, kept in the ice-chest overnight, and on the following day the serum was removed aseptically and diluted with an equal volume of sterile saline. Under a general anæsthetic cisternal puncture was performed, about 20–25 c.cm. of cerebro-spinal fluid were removed, and an equivalent amount of the diluted salvarsanised serum allowed to run into the cisterna magna. The child received during this course six such injections into the cistern at fortnightly intervals, and during the intermediate weeks she received an intravenous injection of 0·15 g. N.A.B. The child's mental condition certainly showed some improvement during this course of treatment, and reference to the table will show that there was a definite but slight improvement in the cerebro-spinal fluid. This course of cisternal injections with salvarsanised serum was followed up with a course of ten intramuscular bismostab injections given bi-weekly, starting with 0·3 c.cm. and working up to 1 c.cm.; total 7·3 c.cm. At the end of this course the blood Wassermann was still very strongly positive, but the cerebro-spinal fluid showed definite improvement (see table, Dec. 15th–16th, 1925). Mentally, however, the child was in much the same condition. She made inane remarks, repeated all that was said to her, and was still very destructive. She was discharged from hospital for the first time on Jan. 1st, 1926. The mother brought her up for a blood test on Feb. 1st, 1926, when she reported that the patient was much more sensible and talked intelligibly. On March 8th, 1926, the child was in the same condition. Protoiodide of mercury, gr. ¼ t.d.s., was ordered.

Malarial Treatment.

Later, as the child was apparently not improving very much, it was decided to try the malarial treatment upon her. She was accordingly admitted again to hospital on April 23rd, 1926. The blood and spinal fluid were tested on the 26th, and on the 28th mosquitoes were applied and about eight of them fed on the patient. There were irregular rises of temperature from about the thirteenth day after the mosquitoes fed, but owing to the child's wild condition it was extremely difficult to take her temperature. Parasites were found in the blood on the 16th day, 20th day, and 22nd day after infection. Apparently the child had only three definite rigors, and the highest temperature recorded was 105° on one occasion and 105·6° on another. The spleen was felt to be enlarged on the 19th day after infection. As the patient was becoming rather anæmic, it was decided to stop the malarial infections on May 22nd, and to this end the patient was given euquinine, 2 gr., three times a day for five days. Parasites were found in the blood two days afterwards, but not on May 25th or 27th, and she had no more rises of temperature after the quinine was administered.

The patient having recovered from the anæmia caused by the malaria, she was discharged from hospital on June 7th, 1926, in the hope that she would gradually show signs of having received benefit from the malarial treatment. Unfortunately this did not prove to be the case, for the mother reports that during the month after her discharge from hospital the child appeared to be worse rather than better. She was quite unmanageable, threw everything about she could lay her hands on, including cups of tea and anything on the table. She screamed and made so much noise that, in the words of her mother, "it was almost impossible to live with her." Things came to such a pass that the parents were threatened with ejectment from their rooms, and the only advice the mother could get from the local medical authorities was to send the child to an asylum. As I was rather loth to lose sight of her I agreed to take her into hospital again. Her condition on admission to hospital for the third time is best given in the words of the staff nurse, as follows:—

"She resembled a wild animal. She screamed at intervals night and day, flung things about, tore up the bed-clothes and wearing apparel, and threw everything on the floor. She was very dirty in her habits. The resident medical officer, who visited the ward at a critical moment, remarked: 'If Dr. Nabarro thinks he is going to do anything with this child—— Impossible!' He thought she was terrible. Her language was choice and at times she was almost unapproachable. She was unable to feed herself, and if any food was given to her it was thrown on the floor."

Intracisternal Injections.

At this time she was given a mixture of potassium bromide with luminal gr. ¼ three times a day and paraldehyde at night when necessary. It was decided to give her another course of intracisternal injections, this time at intervals of one week only. These were given between July 13th and August 17th, 1926, and already after the second injection she appeared to be

more rational, quieter, and spoke in longer sentences than heretofore. Towards the end of August, when the course of injections was completed, she began to be more docile and was bathed with less difficulty. She gradually became cleaner in her habits and took her food nicely. So rapidly did she now improve that by the first week in September she was allowed to run about in the garden with the other children for an hour or two every afternoon. At the end of September she remembered things she had done at home, as, for instance, having had a game at ball with her father in the park, and the toys she played with. She remembered going to school and things the teacher had spoken about. She became interested in her surroundings and friendly in her manner, each day showing a gradual improvement. In spite of this great improvement in her general behaviour, she had sleepless nights, and it was necessary to continue the bromide and luminal three times a day and the paraldehyde at night. The former was discontinued on Oct. 3rd, 1926, the latter, however, had to be given until Jan. 25th, 1927. Between November, 1926, and February, 1927, she was given sunlight treatment, which she rather enjoyed, and which may possibly have done her some good during the sunless days we then experienced. As the blood Wassermann was still fairly strongly positive and the cerebro-spinal Wassermann also somewhat positive, it was decided to give further subsidiary treatment. On Sept. 7th, 1926, protoiodide of mercury pills, gr. ¼, were given twice a day, but these had very soon to be discontinued owing to the diarrhœa they caused. Between Sept. 13th and Oct. 18th she had 14 c.cm. of bistovol (bi-weekly intramuscular injections of about 1·5 c.cm.). The blood and fluid were tested thereafter (on Nov. 9th and 16th), when the former was found to be still strongly positive, the latter almost negative. As I was very anxious to get the blood Wassermann negative, if possible, I decided to give once a week an intravenous injection of 0·3 g. N.A.B. and an intramuscular injection of bismostab, 0·75 c.cm. These combined injections were given for four weeks, but as they appeared to produce toxic symptoms, such as vomiting and marked pallor, the N.A.B. was discontinued and the patient given the bismostab alone. When the blood was last examined, on March 3rd, 1927, it had improved somewhat but was still fairly strong. I decided now to change over to sulfarsenol intramuscularly, but an injection of 0·24 g. seemed to disagree with the patient, so alternatively she was given ten intramuscular injections of 1 to 1·5 c.cm. bistovol. These were completed on May 20th, 1927, shortly before the child left hospital. The details of the treatment given to the patient can best be seen from the summary which follows, and if this be compared with the table the effect of the treatment upon the condition of the blood and cerebro-spinal fluid at any particular date can be ascertained.

Summary of Treatment.

1925.—August 10th to Nov. 3rd, 13 intravenous injections novarsenobillon at weekly intervals—2·3 g.

August 18th to Nov. 4th, six cisternal injections, 21–26 c.cm., 50 per cent. salvarsanised serum and saline at fortnightly intervals.

Nov. 9th to Dec. 12th, ten intramuscular injections bismostab* bi-weekly. Total, 7·3 c.cm.

1926.—March 8th, protoiodide of mercury, gr. ¼, three times a day for six weeks.

April 28th, eight mosquitoes fed. May 13th, temperature 101° (15th day).

May 14th, parasites found.

Euquinine, gr. 2, three times a day from May 22nd for five days.

July 12th to August 16th, seven intravenous injections N.A.B. (weekly). Total, 2·1 g.

July 13th to August 17th, six weekly cisternal injections, 20–25 c.cm., 50 per cent. salvarsanised serum and saline.

* Bismostab is a preparation made by Boots Pure Drug Co., Ltd. It consists of 0·2 g. bismuth metal in each c.cm. of 5 per cent. glucose solution.

In reporting on the blood Wassermann, when two figures only are given, it means that a dilution of serum 1 in 15 was employed with three and five minimal hæmolytic doses, or units, of complement respectively. When four figures are given, these refer to serum 1 in 15 and 1 in 30 dilutions, with three and five units of complement respectively. The figures themselves (4, 3, 2, 1, &c.) refer to the amount of hæmolysis which has taken place in the test-tube, 4 indicating a complete absence of hæmolysis (strong positive). 0 = complete hæmolysis, and 1, 2, 3 progressively diminishing amounts or degrees of hæmolysis. The sign < indicates that the reaction was not quite as strong as the figure before which it occurs. * means that the tube was not quite cleared and that there was not sufficient sediment to call the reaction (1). In the case of cerebro-spinal fluid, the numbers represent the same degree of hæmolysis as in the case of the blood serum, but the amounts of fluid used are different. The four tubes contain respectively 2 vols., 1, ½, and ¼ vol. of cerebro-spinal fluid, giving 1 in 2, 1 in 3, 1 in 6, and 1 in 12 dilutions of the cerebro-spinal fluid, and to each tube is added 3 units of complement only.

Sept. 13th to Oct. 18th, ten intramuscular injections bistovol† (bi-weekly). Total, 14 c.cm.

Nov. 29th to Dec. 20th, weekly injections N.A.B., 0·3 g. (intravenous) and bismostab, 0·75 c.cm. (intramuscular). (Four given, then stopped on account of vomiting and pallor.)

Dec. 24th, 1926, to Feb. 11th, 1927, eight intramuscular injections bismostab, 0·75 c.cm. Total, 6 c.cm.

1927.—March 3rd. As the Wassermann was still positive (4, 1, 0, 0, Kahn P. P. P.), sulfarsenol, 0·24 g., was injected intramuscularly, but as patient was ill after it, resorted again to bistovol, 1–1·5 c.cm., in all 13 c.cm.

May 20th, she was successfully vaccinated prior to going to convalescent home.

Remarks.

While it is as yet too early to regard the patient as "cured," her mental and physical condition show such an amazing improvement and the serology of the blood and spinal fluid have progressed so far towards normality, that I have reported the case in order to encourage others who may have such cases under their care to try similar lines of treatment. An important point which this case brings out is the fact that after even a year's prolonged treatment by various methods the child's condition was apparently no better than it was when treatment was begun. It is, however, possible that if one had waited a few months longer after the cessation of the malarial treatment, an improvement in the patient's mental condition might have taken place, but as I have already stated, the alternative was between sending the child to an asylum or the ejectment of the parents from their home if no further active steps were to be taken. It may be asked why such a variety of drugs and so many different forms of treatment were tried, so that it is impossible to say definitely to which line of treatment is due the success which has been attained. This criticism is valid, but the main object was to see whether a case of juvenile general paralysis could be improved or cured by any means whatsoever. Now that this has been shown to be possible future cases may be treated by any one or more particular line or combination of treatment, in order to ascertain which gives the best results. There can be no doubt that the earlier the case comes under observation and the sooner treatment is started the better must be the outlook for the patient. This was another reason which prompted me not to wait too long for signs of improvement before trying another line of treatment. I may mention here that I have at present under observation two other cases of juvenile paralysis which have had malaria given to them and are now having the ordinary antisyphilitic treatment. It will be interesting to see if these cases do as well clinically and serologically, without the cisternal injections, as the child whose case is above described has done after her combined treatment. Malarial treatment is also being tried on a small number of children whose cerebro-spinal fluid is Wassermann-fast, but who have no symptoms or other signs of disease of the central nervous system.

Conclusion.

If, subsequently, it be found that the treatment of juvenile general paralysis cannot be materially simplified or shortened beyond that of the case herein reported, the question may legitimately be asked—and, indeed, has been asked—whether the expenditure of time and energy, thought and care involved, is really justified. The answer to this question depends entirely upon the future course of this and similarly treated cases. If my patient remains in substantially the same mental condition as she is at present and proves herself educable, as I have every reason for believing her to be, and if she grows up to healthy womanhood and has healthy children, then the answer to this question is unhesitatingly "Yes." Medical attention alone would not have achieved the success recorded, and the fullest recognition possible must be given to the sisters and nurses of the wards in which the patient was for so long an inmate.

† Bistovol is made by May and Baker and is the bismuth acetylamino-oxy-phenylarsinate of Levaditi.

In conclusion, I should like to put on record my thanks to my colleague, Dr. Robert Hutchison, for handing the patient over to my care for treatment; to my assistants, Dr. D. McClean and Dr. B. B. Sharp, for help in many ways and on many occasions during the injections and other manipulations, and in carrying out the pathological investigations; to Colonel S. P. James and his assistant, Mr. P. G. Shute, for help with the malarial infection; and to all others who contributed directly or indirectly to the success of the treatment; and in particular to my staff nurse, Miss Irving, and her assistants, whose infinite patience and great care and attention contributed in no small measure to the recovery of the patient.

CARBUNCLE OF THE KIDNEY,

WITH REPORT OF A CASE.

BY THEODORE THOMPSON, M.D. CAMB., F.R.C.P. LOND., F.R.C.S. ENG.,

PHYSICIAN TO THE LONDON HOSPITAL.

CARBUNCLE of the kidney, though a rare and somewhat unfamiliar condition, occurs often enough to merit recognition as a distinct clinical entity. This, as I hope to point out, is all the more important since the prognosis is generally very good when an early diagnosis is made and active treatment instituted, whereas failure to recognise the condition may lead to disastrous results. It may be described as a hæmatogenous infection of the interstitial tissue of the kidney producing a localised and circumscribed zone of multiple suppurating foci, leaving the remaining renal substance unaffected. There is always a primary focus, as a rule a furuncle of the skin. Israel [7] was the first to observe the condition in 1890, in a case a full account of which was given in 1901 in his classical "Klinik der Nierenkrankheiten." The first complete account was given in 1920 by Barth,[1] who described five cases and pointed out many of the diagnostic and pathological features. Since then many cases have been added to the literature.

The following case is described here since it represents a fairly characteristic clinical picture and illustrates many of the pathological features.

A Case Related.

The patient, a married women, aged 52, developed a bad carbuncle of the neck during January, 1926. This was incised, the pus evacuated, and a steady recovery ensued. Whilst convalescing she took a sea voyage, during which, at the end of the first week in February, 1926, she knocked her left loin rather severely against a bunk. Ten days later she was taken ill with severe pain in the left side, high temperature, and general malaise. There were no urinary symptoms. A diagnosis of influenza and pleurisy was made, and the patient was landed and brought back to England. The patient continued to run an irregular temperature and complain of intense pain in the left side of the abdomen and loin, and her general condition became worse. There were occasional rigors.

The patient was examined on March 5th, 1926, when the temperature was 101° F, the pulse-rate 96 per minute, and respiration-rate 20. On the back of the neck was a large scar of a recent carbuncle. The anterior abdominal wall and the muscles of the back on the left side were rigid, and there was great tenderness on palpation. Deep in the left loin an ill-defined tender swelling could be felt. No other abnormal physical signs were detected. A radiogram of the renal tract showed a normal kidney shadow on the right side, and an ill-defined shadow in the left loin, which looked like an enlarged kidney. The urine revealed nothing abnormal on analysis. Microscopically casts and leucocytes were absent.

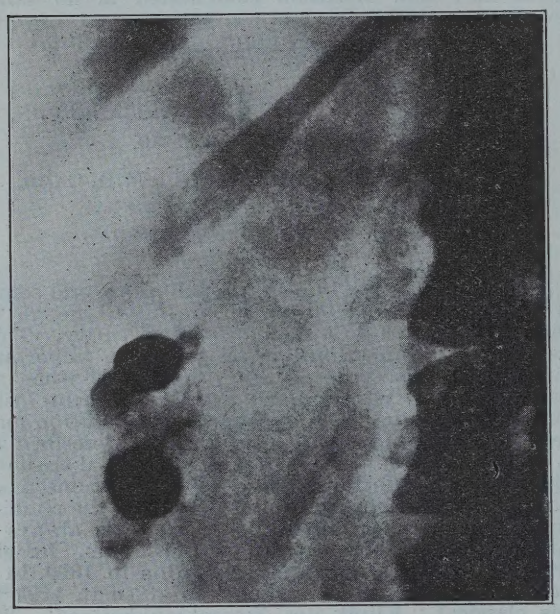
The swelling rapidly increased in size, a diagnosis of perinephric abscess was made, and on March 8th, 1926, the left kidney was explored by Mr. Frank Kidd. A perinephric abscess was opened and drained, and on inspecting the kidney its lower pole was bulged by an ill-defined indurated swelling. Nephrectomy was performed and the wound drained. The pus from the abscess was found to contain *Staphylococcus aureus* in pure culture. During her convalescence a course of

injections of collosal manganese and staphylococcic vaccines were administered. A slow but uneventful recovery followed.

Ætiology.

Carbuncle of the kidney is a rare disease. Up to 1926 Smirnow [10] was able to collect 26, including his own and reported cases. Most of the patients were between 20 and 55 years of age. Barth [1] and Colmers [3] each recorded the condition in a girl aged 10 years,

FIG. 1.



Abscess cavity of a carbuncle in kidney injected with bismuth paste. (*Kindly lent by Mr. Frank Kidd.*)

and this would appear to be the earliest recorded age. The oldest case I can find in the literature is that published by Reschke [9] of a man aged 55 years. Men are more frequently affected than women. Of 33 cases collected from the English and German literature, including the one described above, 23 were males and 10 were females. The greater incidence in men may in part be accounted for by the greater exposure to trauma.

With few exceptions, the individuals affected are, except for a staphylococcal lesion of the skin from which they are usually recovering, otherwise healthy. The primary focus may be, and frequently is, a trivial lesion of the skin, such as a furuncle of the neck. This or a carbuncle of the neck is the source of the staphylococci in most cases. Various other primary lesions have, however, been recorded. Thus it has followed bone infection as in cases described by Souper [11] and Kreschner,[8] whitlow of finger (Fisher [5]), and prostatectomy as in Horn's [6] case. Trauma is not only an important predisposing factor, but also of considerable significance in determining the site of the lesion. A history of trauma was obtained in my case, and although not often mentioned in the literature may frequently occur in some trivial form easily forgotten by the patient. Its importance as a factor in lowering the resistance of the kidney will be referred to again.

Clinical Features.

The onset of symptoms with malaise and intermittent fever is usually gradual and insidious, and generally commences between two and eight weeks after the primary infection. Pain in the side is an early and constant feature. It begins in the loin or lower part of the chest behind, and steadily getting worse soon involves most of one side of the abdomen. The pain is felt as a constant dull ache, does not tend to radiate, and is generally made worse by movement or taking a deep breath. Rigors are frequent. Vomiting sometimes occurs, and in the case of large perinephric swellings there may be a dry cough.

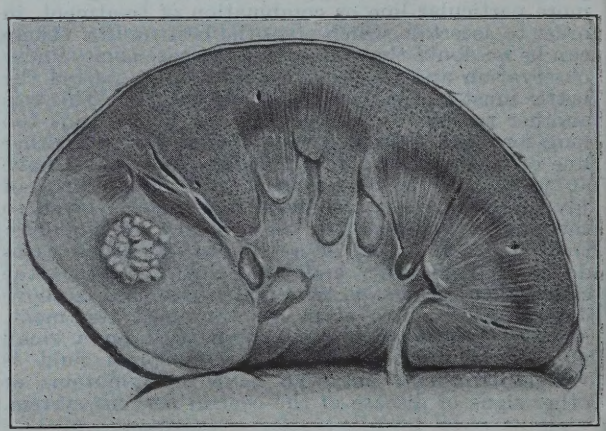
On examination, the respiratory movement of the lower part of the chest on the affected side is restricted and there is early rigidity of the muscles of the back and loin. Pressure aggravates the pain, and after a few days an ill-defined, extremely tender swelling may generally be felt deep in the loin. This may at times actually produce a bulging of the affected side. Urinary symptoms are usually conspicuously absent, but frequency and dysuria have on rare occasions been reported. The urine is generally normal, or a trace of albumin and a few leucocytes may be present, but catheter specimens are sterile. Blood-counts always show an obvious polymorphonuclear leucocytosis. The clinical picture is therefore that of a perinephric abscess.

Diagnosis.

The certain diagnosis of renal carbuncle can only be made at operation. The occurrence, however, of a pyrexial illness, accompanied by chills, pain, and swelling in the loins within a few weeks of a primary staphylococcal infection of the skin, particularly when there has been a history of a blow to one kidney region during the intervening time, should always lead one to suspect the possibility of this condition.

In the first few days of illness, the unexplained pyrexia may suggest an influenzal attack, or, where pain is an early feature, pleurisy or pneumonia may be suggested, particularly as cough and diminished movement over one pulmonary base may occur; but careful examination of the lungs will fail to reveal any other abnormal signs. A *Bacillus coli* pyelitis may be

FIG. 2.



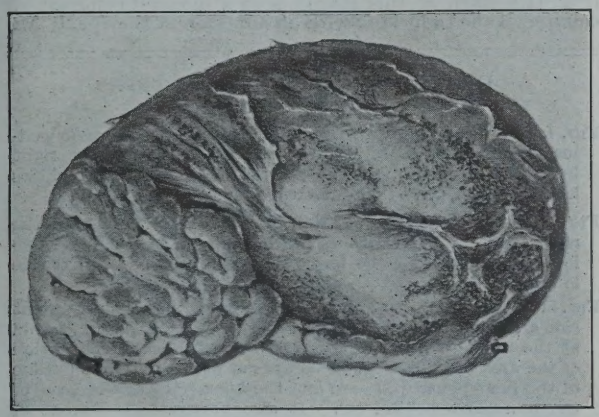
Section of kidney showing area of multiple purulent foci at lower pole, surrounded by a broad zone of fibrous tissue. The renal pelvis is healthy. (*Drawn by W. Thornton Shiells.*)

simulated, but frequency of micturition and dysuria are not common; the urine is nearly always sterile and free from pus, and the usual alleviation of symptoms does not follow the administration of alkalies. Within a few days of onset a deep-seated swelling appears, which is generally recognised as a perinephric abscess. Psoas abscess, and on the right side appendix abscess, or even acute cholecystitis may all have to be excluded by a careful consideration of the history and physical examination. The presence of a primary suppurative lesion may suggest the possibility of secondary metastatic abscesses in the kidney. In this condition the urine always contains a considerable amount of albumin, pus, and organisms. Moreover, the renal function, as estimated by the rate of excretion of dyes, is not impaired in renal carbuncle, whereas gross impairment occurs in secondary metastatic abscesses.

of the kidneys. These important distinguishing features were first pointed out by Barth.[1]

When at operation the perinephric abscess is drained, inspection of the kidney will generally reveal a swelling at one pole, with the point at which it has ruptured visible on the surface. If, after draining what is believed to be a simple perinephric abscess, the wound continues to discharge after a reasonable period of time has elapsed, the possibility that a carbuncle in the kidney has been overlooked should be suspected. In that case a subsequent exploration will be necessary. Considerable help may be obtained by injecting the sinus with bismuth paste or lipiodol, when the presence

FIG. 3.



Outer surface of kidney showing thickened and inflamed capsule, and at the lower pole a yellow necrotic area where the carbuncle has perforated and reached the capsule. (*Drawn by W. Thornton Shiells.*)

of an irregular cavity within the kidney substance may be demonstrated (Fig. 1).

Pathology.

The *macroscopic appearance* of the condition is shown in the accompanying illustrations. On section (Fig. 2) the lower pole is seen to be replaced by a mass, in the centre of which is a number of small yellow purulent foci having a more or less rosette arrangement. Each of these is little bigger than a pin's head. Surrounding these is a broad dense homogeneous zone of fibrous tissue, which merges imperceptibly with the normal kidney substance above, and reaches a much thickened capsule below. No limiting membrane is present. The rest of the kidney has a perfectly normal appearance. The pelvis is a little injected but otherwise healthy. The striking resemblance to the multiple necrotic foci of a skin carbuncle is well seen. From the outer surface (Fig. 3) the inflamed and thickened renal capsule is seen perforated near the lower pole, and the perforation is occupied by yellow necrotic material. It is at this point that the purulent zone reaches the surface, and so, by direct continuity, produces an inflammation of the capsule with abscess formation round the kidneys. Curiously enough, the pelvis is very rarely reached. Although a single carbuncle is the rule, more than one may occur within the same kidney. It is extremely rare for more than one kidney to be affected, but Kretschner [8] records the case of a patient who, after having a nephrectomy for a carbuncle of one kidney, subsequently died of a similar condition in the other.

Microscopic examination in early cases shows that the process begins in the interstitial tissue of the cortex. The yellow areas of softening are occupied by necrotic débris, pus cells, and masses of cocci. Surrounding these is a zone of granulation tissue with leucocytic infiltration and considerable fibroblastic reaction. No trace of renal tissue can be seen towards the centre of the lesion, but on approaching healthy kidney substance little change is observed within the parenchyma, as compared with the interstitial tissue. Here the glomeruli are scanty, replaced by hyaline fibrous tissue, and often surrounded by a hyaline capsule. The tubules show mild catarrhal changes only.

These appearances are in striking contrast with those observed in simple metastatic infections of the kidney seen in pyæmic conditions. Here it is the tubules that are most obviously affected, and these are occupied by renal epithelium, pus cells, and organisms. Where the latter condition is associated with abscess formation, areas of purulent softening are found surrounded by thin pyogenic membranes. These abscesses not infrequently communicate with the renal pelvis.

As in the case of carbuncle of the skin, the *Staphylococcus aureus* can always be obtained in pure culture from the purulent areas.

The special predilection of the kidney to localised infections is extremely interesting. Elimination of organisms from the blood stream may be regarded as a normal function of the kidney, and when this organ is healthy such organisms are always innocuous to it. Lowering of the resistance of the kidney, from whatever cause, may be expected to determine the formation of an abscess within it, and thus trauma of any kind is an important predisposing factor. It has been known, as in Horn's case [6] to follow retention of urine due to prostatic enlargement, and here it is probable that renal congestion favoured the local staphylococcal invasion. In this connexion the experimental work of Brewer [2] is interesting. This worker injected organisms into the circulation of a series of animals, in some of whom the resistance of the kidneys was lowered by various forms of trauma. In 11 out of 16 of the latter animals suppurative foci were found in the kidneys, which in some instances reached the surface and caused perinephric abscess, whereas in those which received no trauma the kidneys remained normal. On microscopic examination the lesions were found to result from plugging of the smaller arterioles and capillaries with organisms.

Treatment.

If the case is seen early medical treatment may be tried, and a course of collosal manganese, staphylococcal vaccines, or sodium nucleinate may be given. When a perinephric abscess is diagnosed, surgical interference will always be required. In that case, as Eisendraht [4] pointed out, simple drainage is never sufficient, and if attempted a subsequent operation will be necessary. In most cases nephrectomy will have to be performed. Colmers[3] analysed the results in 16 cases, and found that of these two patients who had no operation and four who had nephrotomy all died, whereas the other ten patients who had nephrectomy all recovered. Where the carbuncle is found to be single, small, and at one pole, the ideal treatment is to excise it and leave the rest of the kidney, which is always unaffected. This is important, for, as Kretschner [8] has shown, a second carbuncle may occur in the opposite kidney.

As a rule, provided that operation is not unduly delayed, the prognosis is good, and recovery occurs. If no operation is performed death results from subdiaphragmatic abscess, general peritonitis, or even septicæmia and exhaustion.

SIMULTANEOUS BILATERAL ARTIFICIAL PNEUMOTHORAX.

BY A. I. G. McLAUGHLIN, M.B., CH.M. SYDNEY,
TUBERCULOSIS DEPARTMENT, ST. THOMAS'S HOSPITAL.

With Notes on the Radiograms
BY GEOFFREY FILDES, M.B. MANCH., D.M.R.E. CAMB.,
RADIOLOGIST TO THE HOSPITAL.

(WITH ILLUSTRATIVE PLATE.)

IT is well known that double spontaneous pneumothorax is incompatible with life. Fishberg [1] mentions a case which came under his observation, and quotes Hellin, Staehlin, and Gray, who also reported cases. At first sight it would appear that double artificial pneumothorax in the treatment of pulmonary tuberculosis is dangerous and unjustifiable, but in point of fact similar conditions do not obtain in the spontaneous and artificial types of bilateral pneumothorax. In the first place, the collapse in spontaneous pneumothorax is sudden and uncontrolled, and the thoracic viscera have no time to become adapted to the altered conditions, whereas in artificial pneumothorax the collapse is obtained gradually, allowing plenty of time for adaptation in the circulation and ventilation of the lungs. Secondly, in spontaneous pneumothorax an opening is present in the visceral pleura through which organisms from the lung may pass to infect the pleural cavity.

Bilateral artificial pneumothorax was first suggested and carried out in 1913 by Parry Morgan,[2] who also first pointed out the fact that the diseased areas in the lung tend to remain collapsed, while the healthy portions re-expand. This principle of selective collapse in simultaneous bilateral artificial pneumothorax has been studied further by Barlow and Cramer,[3] who have obtained good results in cases of early bilateral pulmonary tuberculosis. Their method is to keep the diseased areas in both lungs collapsed by means of injections at frequent intervals of small quantities of air, and at the same time to allow the unaffected parts to expand. In a previous communication (with F. B. Hobbs [4]) I referred to the difficulties of bilateral selective collapse in comparatively advanced bilateral disease—viz., the presence of pleural adhesions over the diseased areas, and the occurrence of febrile reactions after each refill. Forlanini,[5] Feldman,[6] Burnand,[7] and others have performed consecutive bilateral pneumothorax—i.e., they allow the lung which is first collapsed to expand before collapsing the other lung.

Recent work in France, notably by Rist and Coulaud,[8] has shown that it is possible to have practically complete collapse of both lungs without the onset of dyspnœa or cyanosis, and with considerable improvement in the condition of the patient. Several months ago I had an opportunity of seeing with Dr. Coulaud at the Hôpital Laënnec in Paris a number of these patients, and I was struck by the apparent incongruity between the patients' condition of respiratory and cardiac comfort and the radiographic appearance of practically complete collapse of both lungs. The vital capacity in these cases is much lower than normal, and Rist, Coulaud, and Chabaud [9] offer the explanation that the condition is comparable with the state of affairs present in the lungs of the newly born child—i.e. there is no reserve air, and the child exists on the residual air in the alveoli. Whether this is the true explanation or not, it would appear that bilateral pneumothorax, gradually induced, is not incompatible with life, especially where the diseased area in both lungs is not of great extent.

The following case of simultaneous bilateral pneumothorax appears worthy of record, not only on account of the improvement in the patient's condition, but also because it afforded an opportunity of studying in the same patient the physical signs of two pneumothorax cavities, in one of which were adhesions and a pleural effusion, and in the other a free pleura and no effusion.

A girl, aged 17, was admitted to St. Thomas's Hospital on Oct. 16th, 1926. She had been ill for one month with cough and sputum, pyrexia, night sweats, and progressive loss of weight. She was found to have pulmonary tuberculosis involving the upper half of the right lung, with a small cavity at the apex, and an area of infiltration about the left hilum, spreading into the surrounding lung tissue. Tubercle bacilli were present in the sputum. The radiogram (Fig. I.) shows the extent of the disease in the lungs. For ten days she was kept at rest in bed, and during this time there was an irregular evening temperature varying between 99° F. and 101° F. On Oct. 25th pneumothorax was induced on the right side. Refills were given on the 26th and 28th. A fall of the temperature to normal coincided with the induction of the pneumothorax. A radiogram (Fig. II.) taken at this stage shows a moderate amount of collapse of the right lung with an adhesion at the apex. An interesting feature of this radiogram is that the three lobes of the right lung are shown clearly, with evidence of disease in the upper two. On Nov. 1st pneumothorax was induced on the left side. Whether as a result of this induction or merely as a coincidence, the temperature rose to 102° F. and an effusion into the *right* pleural cavity was observed. The temperature remained high, swinging between 102° F. and 100° F. for three weeks, after which the fluid was withdrawn and replaced by air. A few days after this replacement the temperature became normal. No further effusion or rise of temperature occurred.

During this period, small injections of air, averaging 300 c.cm., were made into the left pleural cavity at intervals of nine days, but they were found not to be sufficient to keep the lung collapsed, and the interval was shortened to four days. On account of the fact that the patient breathed entirely with the left lung, it expanded again, and the pneumothorax had to be reinduced on at least four different occasions. It was then decided to bring about more collapse with larger quantities of air, and this was done, but care was taken not to bring the intrapleural pressure on the left side above zero. In order to keep the lung partially collapsed, it was found that 600–700 c.cm. of air given at weekly intervals were necessary.

The fact that the pleura becomes sclerosed and resistant after a pleural effusion is well illustrated by the rapid rise of the intrapleural pressure from a marked negative to a marked positive pressure after the injection of a small quantity of air, e.g.:—

Jan. 10th, 1927, right side, −14 −7; 250 c.cm. air, +7 +14.

A larger quantity of air injected into the left pleural cavity does not cause a similar rise in the intrapleural pressure, e.g.:—

Jan. 11th, left side, −10 −5; 550 c.cm. air, −10 −1.

At no time did the patient experience respiratory or cardiac distress, although there was a considerable degree of collapse of both lungs. While giving a refill on the left side, the onset of a slight sensation of tightness of the chest was taken as an indication that

DESCRIPTIONS OF ILLUSTRATIONS.

(*See Plate.*)

FIG. I. shows the appearances before treatment. There is well-marked fibroid disease involving the upper half of the right lung with cavitation of the apex (A). The left lung shows hilum disease extending outwards almost to the pleura.

FIG. II. shows demarcation of the three lobes after collapse of the right lung. Disease with cavitation is seen in the upper two lobes (1, 2), whereas the lower lobe (3) is clear. The left side is unaltered.

FIG. III. after partial collapse of both lungs, shows on the right side adhesions to the chest wall and a small collection of fluid at the base. On the left side there is a marked diminution of the area of infiltration as compared with Fig. I., the outline of the lung being well seen and the apex lying at the level of the fourth rib behind (A). It also illustrates the mode of collapse when no adhesions are present—i.e., the apex is displaced downwards.

FIG. IV. shows practically the same appearance as Fig. III., except that the left lung has been allowed to expand a little. It now shows much sharper definition of the area of infiltration suggesting early calcification.

enough air had been injected. This symptom usually passed off within five minutes. I did not aim at securing the practically complete collapse obtained by Rist and Coulaud, but the degree of collapse obtained was much more than the selective collapse advocated by Barlow and Cramer.

An interesting point is that no febrile reactions occurred, with the exception that the onset of pleural effusion on the right side was attended with pyrexia. It appears to be a significant fact that the effusion occurred on the right side where there was a pleural adhesion, and not on the left side where there was a free pleura.

In April, 1927, the patient was able to get out of bed for four hours during the day and to take a fair amount of exercise. The degree of collapse in both lungs is seen in the radiograms (Figs. III. and IV.). There is no cyanosis or dyspnœa and very little cough; the temperature is normal; the sputum is scanty and does not contain tubercle bacilli. During one period the left lung was compressed to a little more than half its full volume. It was noticed that during this time the weight remained stationary. As soon as the lung was allowed to expand a little the weight began to increase.*

The interval for refills has now been increased to 14 days for the left side and 28 days for the right side.

NOTE ON THE PHYSICAL SIGNS.

Percussion.—The percussion note was uniformly hyperresonant over the whole lung area on both sides, with the exception of a small area at the right base where the note was impaired owing to the thickened pleura resulting from the pleural effusion. The area of cardiac dullness was diminished considerably.

Breath Sounds.—On auscultation the breath sounds were absent over the whole of the right lung, but over the left lung they could be heard invariably, even when a considerable degree of collapse of the lung existed. This would seem to show that absence of the breath sounds is not a constant concomitant of pneumothorax. Indeed, it is a comparatively common occurrence, in the out-patient department, to see cases of partial spontaneous pneumothorax in which the character of the breath sounds vary little, if any, from the normal.

Coin or Bell Sound.—The coin sound developed on the right side after the absorption of the pleural effusion, becoming more marked as the pleural membrane became more sclerosed. On the left side, the coin sound on numerous examinations was never elicited. This fact led me to investigate more closely the incidence of the coin sound in the other cases of artificial and spontaneous pneumothorax under my care, and I have come to the following conclusions: (1) The coin sound is elicited in its most marked and characteristic form when the pleura has been thickened or sclerosed by the onset and subsequent absorption of a pleural effusion, either serous or purulent. (2) The main condition necessary for the production of the coin sound is not, as Fishberg[10] maintains, the presence of fluid, but the hardening and increased elasticity of the pleural membrane so that it resembles a sounding-board, producing forced vibrations. (3) The same explanation holds for the production of the coin sound over cavities in the lung—viz., that there must be an air space enclosed by thick resistant walls to amplify the vibrations of the metal. (4) The coin sound is rarely heard over a pneumothorax cavity where a pleural effusion has not occurred. If it is elicited over such a cavity I venture to suggest that this is a case of pure resonance, as distinct from forced vibration, and that the important feature is therefore an accidental correspondence between the wave-length and the dimensions of the cavity. (5) The intensity of the coin sound can be increased a little by raising the pressure in a pneumothorax cavity from a negative to a positive pressure, but the tension in the cavity is not, as Bendove[11] suggests, the primary factor.

Subfascial Emphysema.—On one occasion, for five days after a refill on the left side, sharp crackling crepitations, synchronous with the systole and diastole of the heart beat, were heard over the cardiac area. These sounds were due apparently to subfascial emphysema, which is a rare occurrence in artificial pneumothorax.

* *September, 1927.*—Progress has been maintained. The weight is increasing steadily, and all symptoms such as cough, sputum, and pyrexia have disappeared. The patient, who was discharged from the hospital in May, is now living at home, and is able to lead a comparatively normal life.

A CASE OF FIBROCYSTIC DISEASE OF THE LUNG.

BY P. J. KERLEY, M.B. N.U.I., D.M.R.E. CAMB.,
L. R. SHORE, *M.C.*, M.B., M.R.C.P. LOND.,
AND
W. A. YOUNG, M.B., L.R.C.P. LOND.
(*From the Royal Chest Hospital, City-road, E.C.*)

(WITH ILLUSTRATIVE PLATE.)

THE literature contains descriptions of several cases of cystic degeneration, both congenital and that following acute fevers in very young children. Oudendal,[1] who has recently examined the literature thoroughly and has published exact pathological records of cases which have come under his notice, describes only one which resembles our case given below histologically. In Oudendal's case only a limited area in the right lower lobe was affected. Chronic pulmonary tuberculosis was associated with the cystic condition. He gives the name of "fibrocystadenoma pulmonare" to the pathological condition, but his description and his plates suggest a chronic inflammatory process rather than non-malignant tumour formation. In one case observed by W. A. Young (not yet reported) localised areas of fibrocystic change were found in both lungs similar to the case above reported. The cause of death in this case was tuberculous pericarditis. No trace of tuberculous infection was found in the lungs.

Our Case Described.

The following is the report of our case, which we believe to be of a nature previously undescribed:—

A woman, aged 32, attended the out-patient department, Royal Chest Hospital, on Feb. 12th, 1926, complaining of cough and dyspnœa. She had been in her usual health till October, 1925, when cough began. There was no expectoration, but cough increased and compelled her to give up her household duties towards the end of January, 1926. Shortness of breath became marked in February, and there was also complaint of left submammary pain. Past health had been satisfactory, except for "pleurisy" on the left side eight years previously. There had been steady loss of weight. In 1918 the weight was 12 st. 10 lb., in 1923, 9 st. 4 lb., and on Feb. 12th, 1926, 7 st. 12 lb. in ordinary clothes. She had borne two children, the youngest being 2½ years old. There was no family history of tuberculosis.

Examination showed a spare, slightly built woman, of height above the average. There was slight cyanosis, evident dyspnœa on slight exertion, and some clubbing of the fingers. The expansion of the chest was very poor;

[1] Oudendal, A. J. E.: Ueber Epithelproliferationen und cysten in den Lungen, Virchow Archiv f. Path. Anat., 1923, ccxliv., 59–83

there seemed to be some retraction in the right supraclavicular region. The vocal fremitus and vocal resonance were equal all over, the percussion note was fairly good, the air entry was weak. Bronchitic signs were scanty, but rather more on the right side than on the left. The heart seemed normal in position, and the sounds were natural. The whole picture of cyanosis and dyspnœa, in excess of the findings on physical examination, suggested the possibility of some obstructive tumour in the mediastinum.

Dr. Kerley reports thus on X ray examination on Feb. 4th, 1926 :—

Heart normal. Diaphragmatic movements restricted on both sides. Lungs: Both lungs are diffusely infiltrated, with the exception of the apices. There is a peculiar meshwork appearance between the separate foci of infiltration. The condition is very atypical of tuberculosis, and suggests rather diffuse carcinomatous metastases. Trachea is displaced to the right and appears compressed. Thickened interlobar pleura on the right side.

The patient was admitted to hospital on March 12th, 1926. While she was at rest in bed the temperature varied from 97·6° to 99·4° F. for the first four weeks, the evening temperature being about 99°. During this period the pulse ranged from 80 to 130, and the respirations from 20 to 34. She was blue and distressed even while at rest in bed. The cough was troublesome, but sputum was scanty, though râles were heard at both apices. There was frequent complaint of pain in the left submammary region, and some hyperæsthesia was found in the seventh, eighth, and ninth spaces. The urine was normal.

On the supposition that there was a neoplasm, investigations were made to identify a primary growth. Laryngoscopic examination and radiological examination of the intestinal tract showed no abnormality. Pelvic examination showed vagina and uterus to be normal. The sputum contained pus cells, but no cells suggestive of new growth were found. There were no red blood cells and examination for tubercle bacilli was negative on six occasions. The Wassermann reaction was negative.

Progress.—During the fifth week the temperature was normal, the respiration-rate fell somewhat, and there seemed to be a definite improvement. The colour improved though the cough was still troublesome. The patient began to get up. Râles were noted at both apices as before, and in the back on the right side. The percussion note seemed impaired over the right side, and the air entry rather weaker. Up to the fifth week the patient had lost 1 lb. in weight. The improvement was not maintained, and dyspnœa forced her back to bed. Between the sixth and the tenth week the temperature was rising to 99·6°, the pulse to 140, and the respiration-rate occasionally to 35 or 40. During this period there was marked loss of flesh and strength, and the patient was scarcely able to get up at all. The trachea was slightly displaced to the right, some dullness was found in the first and second spaces on the right of the sternum. Bronchitic signs were heard in the lungs, first on the right side, later on both sides. The patient died on April 28th, 1926.

Post-mortem examination (28/5/26).

External appearances: Moderately well covered; clubbing of fingers and toes of moderate degree; very marked post-mortem discoloration.

On section: The right lung filled the right chest, the left lung showed partial collapse. Dense adhesions over the anterior margin of right lung below apex, and chiefly attached to an accessory lobe occupying the antero-inferior angle of the right upper lobe; numerous interlobar adhesions between accessory lobe and upper and middle lobes; some recent clear fibrinous exudate over the outer surface of both lungs, with a few cheesy flakes over the left lower lobe; no adhesions over the left lung; no excess of fluid in either pleural sac. Both lungs showed irregularly nodular surfaces; the nodules varied in size from that of a small pea to the largest, on the diaphragmatic surface of the right lung, which measured approximately 1¼ by 1⅞ inches; they were not spread along the thin margins of the lung like emphysematous bullæ, but distributed generally over the surface; when cut into they appeared to contain gas under pressure (Figs. I. and II.). Their outer walls varied with their size, the largest showing fairly dense outer walls. Their lining membranes were smooth and of a pale grey colour. No cysts were found to contain any exudate. A few showed partial loculation or thin bands running from wall to wall. The condition was generalised, and lung tissue of normal appearance was only found in the small accessory lobe in the right lung and in a few small areas beneath the pleura in the left lower lobe; the cysts varied in size from the largest mentioned to pin-head size. There appeared to be an increase of fibrous tissue in the septa between the cysts. The glands in the hila showed some acute congestion, but no appearances of chronic infection. Some muco-pus was found in the main bronchi and their largest branches. The tracheal mucosa was not congested. Slight general enlargement of mediastinal glands. The remaining organs were normal.

Histological Appearances.

1. *Lungs.*—The pleura shows some general thickening. The interlobar septa are considerably increased in thickness, and appear as large fibrous areas of irregular shape. The lung tissue proper consists of small isolated areas varying considerably in their appearance from normal alveolar structure to catarrhal and early pneumonic areas. Some collapse and changes of an emphysematous nature are present. The cysts vary very much in size, in the character of their epithelial linings, and in their association with surrounding tissues. From the simple flattened endothelial lining of the emphysematous bulla there are all gradations through the simple cuboidal epithelium of the small contracted alveoli, which are progressively lined with cuboidal, low columnar, and transitional columnar epithelium of the larger cysts. With few exceptions there was no intracystic exudate and no desquamation of the lining membranes. This is in marked contrast to the bronchi and bronchioles, which show evidence of both chronic and recent subacute catarrhal changes. In both bronchi and bronchioles there are numerous areas of "epidermisation," œdema, congestion, and desquamation of epithelium, hyperplasia, and early cystic degeneration of the submucous bronchial glands, and purulent exudation into their lumina. Several cysts show variation in their lining membrane from flattened endothelium in one portion of their wall to cuboidal and transitional columnar in another portion. In many cases the walls are smooth and the contour comparatively regular. In those with a more differentiated epithelium, irregularities of outline and downgrowths of epithelium with irregular "pouching" of the walls, almost amounting to an adenomatous condition in some areas, are not uncommon. The stroma surrounding the cysts is, in some areas, fibrous tissue. In others there is a moderately cellular "granulation tissue" with young fibroblasts, small mononuclears, endothelioid cells, large mononuclears containing pigment, a few eosinophils, and an occasional plasma cell. In a few cases the cysts are immediately contiguous to simple lung tissue. The "granulation tissue" is almost absent from some areas of the lung where more advanced fibrosis is present, but is present in considerable amount in other areas. The vascularity of the "granulation tissue" is of moderate to marked degree. No thromboses were found, but numerous arterioles show some degree of obliterative endarteritis. Careful search of the granulation tissue areas showed a few small "giant cells," not of tuberculous type, but always associated with heavy deposits of carbon pigment and probably of the "foreign-body giant-cell" type. No tubercle bacilli were found in several sections examined, and sections stained to show other organisms did not reveal any in cystic or alveolar exudates. A few Gram-negative bacilli and diplococci were found after prolonged search in the exudate of the bronchi. No unstriped muscle-fibres were found in any cyst wall, and elastic tissue was scanty or absent.

2. *Thymus.*—An area of lymphatic tissue, which was considered originally to be a lymphatic gland, but which, on section, showed remnants of thymus structure, was found densely adherent to the anterior margin of the right lung. It measured roughly ¾ by ½ by ½ inch, and was buried in dense fibrous tissue.

3. *Glands in the hilum of the right lung* show some endothelial and general lymphoid hyperplasia with congestion, probably terminal in origin.

Discussion.

The age of our patient precludes the possibility of a congenital origin of generalised fibrocystic disease. Tubercle has been excluded. Syphilis is a possible cause, and is suggested by the amount of obliterative endarteritis present. The Wassermann reaction was tested only once with negative result, and the Sigma reaction and a Wassermann reaction after a provocative injection of novarsenobillon were not tried. No evidence of mycotic or parasitic infection of the lung was found, and the condition was quite unlike that produced by chronic infection with catarrhal organisms. The condition appears to be analogous to fibrocystic disease of the breast, and to be due to toxic action (rather than direct infection of the lung), producing gradually increasing fibrosis, loss of elastic tissue, "occlusion-cyst" formation with irregular epithelial hyperplasia, and metaplasia and eventual loss of function. The inflammatory changes are considered to be of a secondary nature and of comparatively recent origin. The presence of gas under pressure in some of the cysts possibly represents excretion of gases from the blood.

The X ray appearances of this unique case bear a remarkable resemblance to those of so-called miliary carcinoma of the lung. On close examination of the skiagram the prominent features are: (*a*) An extensive fine network of striations, involving the whole of both lungs with the exception of the apices (Fig. III.). The striations are finer than the normal lung markings, coarser than the markings of chronic stasis, and ramify in a haphazard fashion not seen in either of these conditions. (*b*) Scattered about the striated areas are small dark spots, not homogeneously opaque, and having no definite contour. In contrast to the clear cystic areas immediately about them the spots appeared relatively opaque. From the post-mortem findings there is no doubt that they correspond to the small areas of lung tissue left.

Miliary tuberculosis was at once excluded, as the characteristic, or the typical, clear-cut millet seed opacities were absent and the apices were free. So-called miliary carcinoma, which is occasionally seen secondary to carcinoma of the stomach, gives a similar picture. The only point which might help to differentiate the two conditions is that in carcinoma the striations are somewhat finer and the spots more regular in outline and more opaque. The presence of a rare disease of the lungs gave rise to the erroneous diagnosis of a mediastinal neoplasm. The condition dated from December, 1925, or at latest from February, 1926, when she came under observation. The duration was certainly four months, and more probably six. A high degree of cyanosis and dyspnœa, with physical signs of an indefinite character, led to a search for a cause of deficient air intake.

The cause was evidently intrinsic in the lung substance. Steady loss of weight of long standing suggested neoplasm, and this suggestion received support from radiography. The very indefinite physical signs left the diagnosis doubtful; the presence of parasternal dullness, weaker air entry on the right side, and displacement of the trachea which appeared later, suggested the possibility of partial obstruction of the right bronchus. This displacement may be explained by the pleurisy in the region of the upper and middle lobes, or by an unequal expansion of the two lungs, which caused a displacement of the mediastinum to the right. This is remarked upon post mortem, and is borne out by radiological findings.

Clinical and Laboratory Notes.

A CASE OF FAMILIAL DISSEMINATED SCLEROSIS.

BY CLIFFORD E. ALLEN, M.B., B.S. LOND.,
LATE CLINICAL ASSISTANT TO THE NEUROLOGICAL DEPARTMENT, GUY'S HOSPITAL.

CASES of familial disseminated sclerosis are of extreme rarity; in fact, it has been stated that the total number reported can be counted on the fingers. J. R. Reynolds [1] records two cases, one being that of a family in which three members were affected. André Léri [2] had a case in which two daughters and the mother were affected, the mother having contracted the disease when over 50 years of age. A few less authentic cases have been recorded in a paper by Donald Frazer.[3] Many cases of familial nervous degenerations, such as Friedreich's ataxia, have been shown as "familial disseminated sclerosis," but careful investigation of the family history should prevent confusion. The history in the case recorded here is as follows:—

The parents are both alive and well. One married son, aged 40, is alive and well. One living daughter suffers from disseminated sclerosis, and one son and one daughter have died from the disease. The maternal grandfather died of "heart disease," aged 49; the grandmother died aged 62. The paternal grandfather died aged 80, and the grandmother died aged 30 (cause unknown).

History of the Dead Son (supplied by courtesy of the Director-General of Military Services, Ministry of Pensions).—Died at the age of 32; married; one child alive and well. He was wounded in the left leg during the war. In 1921 he developed "neurasthenia," and complained of seeing double. In 1922 he complained of weakness of the legs and shakiness of the hands. On examination it was found that his right grip was greater than the left; he had nystagmus and exaggerated knee-jerks. His right ankle-jerk was greater than the left, and his right plantar reflex was extensor. The condition was diagnosed as disseminated sclerosis.

In August, 1923, both plantar reflexes were extensor and the abdominal reflexes were sluggish; the right reflexes were still brisker than the left. Both legs were spastic. The left pupil was larger than the right, although both reacted to light and accommodation. He had nystagmus and strabismus, spastic gait, ataxia, and slow speech. He fell with his eyes closed, and had great incoördination and tremors of the hands. In April, 1925, he was bedridden and had incontinence of urine. He squinted, and his speech was unintelligible. His reflexes were similar to those found in 1923. His left pupil was still larger than the right, and both reacted. He died in 1926, and was certified as having died of disseminated sclerosis.

[1] Brain, 1904, xxvii., 163.
[2] Rev. Neurol., 1924, pt. 1, xxxi., 788.
[3] Glasgow Med. Jour., 1880, xiii., 199.

History of the Dead Daughter (kindly given by Dr. Ashley Steel).—Died aged 35; single. The time of the onset of the disease is unknown, but on April 3rd, 1922, the patient's knee-jerks were exaggerated, and there was a loss of power in the muscles of her leg, most marked in the peronei; she had no ankle-clonus nor extensor plantar reflex. By July 4th, 1923, she had developed intention-tremor and ataxia of the hands and feet. She showed mental degeneration. On April 20th, 1924, her left pupil was larger than the right, but reacted to light and accommodation. No nystagmus was present; the discs were pale, but there was no atrophy. Her arm-grips were weak, but she had no intention-tremor. All arm and leg reflexes were exaggerated. Her abdominal reflexes were absent and her plantars were extensor. She complained of posterior root-pains.

On Jan. 8th, 1925, she had diplopia and her condition remained unchanged until April 2nd, when she had acute pains of left renal distribution. Radiogram and urine were then normal, but on July 2nd she had a few pus cells in her urine; there were no casts. On Oct. 8th her pupils reacted sluggishly and her reflexes were exaggerated. On the sensory side she had definite loss to pain, heat, cold, and touch, below the first thoracic nerve. On Jan. 7th, 1926, she had anæsthesia on the left side up to the seventh cervical nerve. Her feet were œdematous and she had incipient heart failure. Lumbar puncture showed diminished pressure but clear fluid. The Wassermann reaction was negative. Lange's test, albumin, sugar, and cells were normal. Towards the last she suffered from flexor spasms and became gradually weaker. She died on March 20th, 1926.

History of the Living Daughter.—Her age is 22. She was first seen on Jan. 25th, 1922, and stated that she fell downstairs three weeks ago, but did not hurt herself. The next morning she noticed that she was numb in the left side and had difficulty in using her left hand. She improved for a fortnight and then relapsed, her right hand also becoming numb. On examination she had slight myopia and nystagmus on looking laterally. The cranial nerves were normal, except for slight weakness of the left face and slight deviation of the tongue to the left. There was no sensory change except slight loss of the sense of position of the left hand, with some astereognosis. The left abdominal reflexes could not be definitely obtained. The right knee-jerk was brisker than the left, and the left plantar reflex gave a doubtful extensor response. The right plantar and other reflexes were normal. A diagnosis of disseminated sclerosis was made.

Five months later she developed pain in the left side, and her left hand and arm became weaker and painful. On May 16th, 1923, she had a definite relapse, and her left arm and leg became much weaker. Her vision was now dim. Five months afterwards again she had more pain in her left arm. On Dec. 11th, 1924, she developed petit mal. She also complained of girdle-pains and of paræsthesia over the fifth nerve, the corneal reflex being normal. Her condition remained about the same until April 19th, 1925, when it was found that the right pupil was larger than the left. She had crossed anæsthesia, slight left facial weakness, and her left hand was still weak. She had incoördination of her left limbs and a positive Romberg's sign. On Feb. 18th, 1926, she had slight nystagmus in all directions, most marked to the left, with slight left facial weakness and diminished sensibility to cotton-wool and pin-prick over the left side of the face and body. The left limbs were weaker, more spastic, and less well coördinated than the right.

The plantar reflexes were extensor; the abdominal reflexes were not obtained. Although Romberg's sign was negative, she tended to fall to the left, and was not steady. On August 18th her condition was the same except that there was an area of hyperæsthesia over the third thoracic nerve-root distribution. No change of importance was noted when she was examined on May 1st, 1927.

It is interesting that this disease should have picked out three members of a family in this manner, and it is very remarkable that two of those affected should complain of root-pains, which are uncommon in disseminated sclerosis.

I should like to express my thanks to Dr. Ashley Steel and the Director-General of Medical Services, Ministry of Pensions, for the records which they supplied; and to Dr. C. P. Symonds for his encouragement and permission to publish details of the case of the living daughter. Dr. R. N. Ironside and Dr. M. Critchley have kindly assisted with references.

A CASE OF
PERSISTENT AURICULAR FIBRILLATION
IN A CHILD OF SIX.

BY D. G. LEYS, M.B., B.CH. OXF., M.R.C.P. LOND.,
JOHN AND TEMPLE RESEARCH FELLOW, ST. THOMAS'S HOSPITAL, LONDON;
AND
H. B. RUSSELL, M.D., M.R.C.P. LOND.,
CHIEF ASSISTANT, ELECTROCARDIOGRAPHIC DEPARTMENT.

THE following case came under our observation.

Clinical History.—The patient, aged 6, is the only living child; his brother, one year older, died of broncho-pneumonia in 1926. His father and mother are well and the boy has had no previous illness which has given cause for anxiety.

About the beginning of March he complained of stomach-ache and seemed feverish; the onset was fairly abrupt. His only other symptom was headache, but a few days later he began to cough, and with each bout became breathless and blue in the face. There was no nasal discharge nor considerably; his general condition has remained very good and the cyanosis only appears with exertion. During his stay in hospital, in spite of a restricted diet, he has become very fat. From a throat swab taken the day after admission a bacillus was cultured morphologically identical with the Klebs-Löffler bacillus. Three further swabs taken in the course of the next two weeks all proved negative. No signs of a faucial or pharyngeal membrane were seen, nor were there any symptoms of laryngitis. No evidence of peripheral neuritis was found.

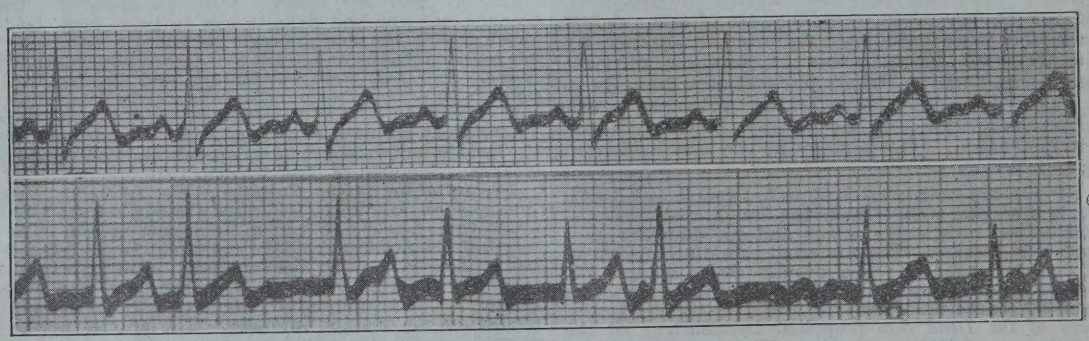
Treatment.—Drugs were administered as follows: (1) Digitalis. ℥xv. of the tincture were given in the first 24 hours and gr. 1/200 of Nativelle digitalin daily for the next 8 days. (2) Antidiphtheritic serum, 5000 units, was injected on the second day. (3) Sodium luminal was given (gr. 1 to 1½ daily) after April 15th until the appearance of a diffuse erythematous rash necessitated its withdrawal. The drug was given to reduce a restlessness due, not to a morbid excitement, but to a natural boyish energy. (4) Quinidine was given in graduated doses during the fortnight May 6th to 19th, beginning with gr. 1½ daily and reaching a maximum of gr. 24 in the day. In all, gr. 80 were given.

Throughout no therapeutic effect could be noted.

Comment.

Of the two electrocardiographic tracings reproduced the first (A) shows a normal complex with some sinus arrhythmia; the second (B), which was taken on the same day (March 31st, 1927), is typical of auricular fibrillation. All subsequent tracings (taken frequently throughout the period of active treatment) have shown the same condition.

The ætiology in this case seems very doubtful; the culture of a bacillus morphologically identical with the Klebs-Löffler is the only evidence suggesting a diphtheritic toxæmia as the cause. J. Parkinson [1] has recorded a case of combined heart-block and auricular fibrillation developing in a man of 22 three weeks after the onset of a pharyngeal diphtheria; joint pains and a cervical adenitis accompanied the onset of the condition. Dr. Foord Caiger informs us that he has not observed any definite case of auricular fibrillation in the course of his long experience of diphtheria in the Metropolitan Asylums Board Service; he points out also that serious heart lesions



Two electrocardiograms taken on March 31st. The upper one (A) shows a normal complex with some sinus arrhythmia. The lower (B) is typical of auricular fibrillation.

complaint of sore-throat. He continued at school till March 29th, when he was admitted to hospital.

When first examined he was seen to be cyanosed, even when lying quite still, but not particularly distressed or dyspnœic. His pulse was completely irregular and of very variable pressure, and there was a good deal of cardiac dilatation, a diffuse apex beat being felt in the sixth intercostal space, one inch outside the nipple line. During the first 48 hours of observation the heart showed three distinct rhythms: (*a*) complete irregularity, like that of an untreated auricular fibrillation; (*b*) regular tachycardia (rate 160 to 170 per minute); (*c*) regular tachycardia, broken by an extrasystole occurring every fifth or sixth beat (rate 120 to 130). This last rhythm was maintained for several hours consecutively, and while it continued each pulsation reached the radial pulse—i.e., the apical and radial rhythms corresponded.

The temperature was slightly raised for the first few days (99° to 99·5° F.). The liver and spleen were not enlarged, nor was there any œdema. The tonsils were moderately swollen and very red.

Since the first few days rhythm (*a*) has been constant, but the number of beats per minute has fallen very con-

in diphtheria are always associated with a severe faucial infection which could scarcely have escaped recognition had it occurred in the case of which we write. G. A. Sutherland and C. F. Coombs [2] have recorded the death of a boy, aged 5, from auricular fibrillation and heart failure, within six days of the onset of a first attack of rheumatism. The heart post mortem showed an extensive myocardial degeneration.

It seems clear that in the present case some degree of myocarditis was present, occasioning extrasystoles, and probably auricular flutter, and ultimately leading to auricular fibrillation. The fact that the boy's previous health was good would seem to indicate that the condition arose as the result of either a severe strain—of which there is no history—or, more probably, from the selective action of some poison. One of us (D. G. L.) has observed on a previous

[1] Heart, 1915–17, vi., 13. [2] Ibid., 1913–14, v., 15.

occasion the rhythm due to the regular occurrence of extrasystoles develop in a girl of 8 years of age who had been for some weeks in bed, under treatment for rheumatic endocarditis (mitral disease). She was not receiving digitalis at the time and had been progressing very satisfactorily. The arrhythmia lasted for 24 hours, during which time she showed signs of incipient heart failure—nausea, vomiting, pulmonary congestion, enlargement of liver and spleen—which disappeared when the normal rhythm returned. The boy, whose case is described above, gave no history of rheumatism and showed no evidence of infection except from the appearance of his tonsils.

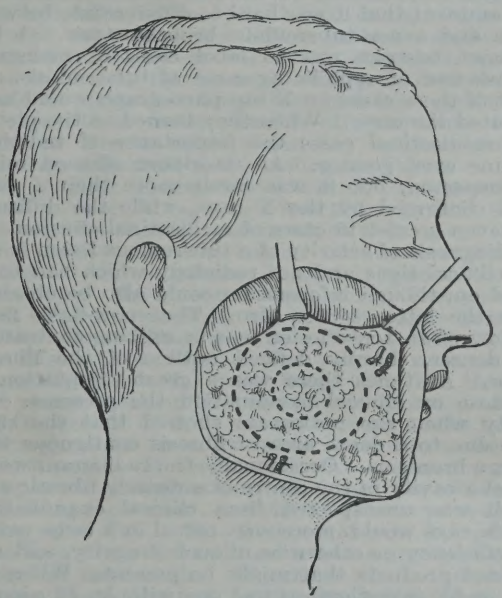
Our thanks are due to Dr. Reginald Jewesbury, under whose care the boy was admitted, for permission to publish an account of his case.

NOTE ON A NEW METHOD OF TREATING CARCINOMA OF THE CHEEK.

BY NORMAN PATTERSON, M.B., CH.B. EDIN., F.R.C.S. ENG.,
SURGEON TO THE THROAT, NOSE, AND EAR DEPARTMENT, LONDON HOSPITAL.

SURGICAL treatment of carcinoma of the cheek presents considerable difficulties. The condition is seldom seen in its early stages, and generally by the time the patient comes under observation the growth has involved a large area of the cheek. Let us consider in the first place the treatment of a tumour occupying a central position which has not yet involved the angle of the mouth, and has so far not

FIG. 1.



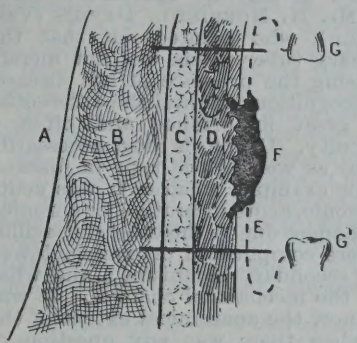
The small circle indicates position of tumour; the large circle shows extent of tissue removed. The facial artery and vein are excised between ligatures. (Semi-diagrammatic.)

spread to the upper or lower alveolus. In such a case excision with the knife may be practised, but I believe that all cancers affecting the mouth and pharynx are preferably treated by diathermy. Diathermy of the cheek presents special difficulties. It is quite easy, by employing the diathermy-excision method, to keep well wide of the margin of the growth, but it is extremely difficult to destroy the deep portions of the tumour without jeopardising the skin of the cheek. It must be remembered that the cheek increases somewhat rapidly in thickness as it passes backwards from the angle of the mouth to the anterior border of the ascending ramus of the jaw, and that if diathermy be employed destruction of the skin is more likely to occur the nearer we approach the angle of the mouth. I have treated a number of cases by diathermy but the results have been unsatisfactory, no case having remained without recurrence for more than two years.

Recently I have devised a technique which I consider will be followed by better results.

After the usual preliminaries, which include removal of all septic teeth, the following method is adopted. Under chloroform anæsthesia an incision is made through the skin. It commences just below the attachment of the auricle and runs down the posterior border of the ascending ramus of the jaw as far as its angle. It is then carried forwards

FIG. 2.



The portion between the thick transverse lines is removed at operation. A = Skin. B = Gauze packing. C = Fat. D = Muscle. E = Mucous membrane. F = Tumour. G = Teeth. (Diagrammatic.)

FIG. 3.

along the lower margin of the jaw as far as the symphysis. In making the posterior part of the incision it is important to avoid wounding the parotid gland which lies near the surface. The skin, and the skin only, is reflected in an upward direction well beyond what are considered to be the limits of the growth. The facial artery and vein are now exposed and ligatured as they cross the lower margin of the mandible. These structures are next dissected upwards and from an inch to one and a half inches of both artery and vein are resected. A broad strip of ribbon gauze is packed underneath the skin flap so that it is well removed from the underlying tissues of the cheek. The patient's mouth is widely opened with a gag, and from the inside the growth, together with an adequate margin of healthy tissue, is removed with the diathermy knife or saw. The gauze packing, having served the purpose of protecting the skin flap from the action of the diathermy terminal, is now removed. It will be observed that there is a large hole in the cheek caused by the removal of the tumour. The skin flap is turned down and stitched in position. There has been no tendency to sloughing of the skin in the two cases in which I have performed this operation.

In cases where the periosteum of the upper or lower jaws is affected, further diathermy will be necessary before replacing the flap, and this can be best carried out through the opening in the cheek with the button applicator. Where the disease extends backwards and involves the mucous membrane over the ascending ramus, diathermy must be freely applied in this neighbourhood. In some cases it may be deemed advisable to resect a portion of the ascending ramus itself. In cases where the growth approaches the angle of the mouth it may be necessary to remove by ordinary cutting methods a part of the whole thickness of the cheek including the skin, the posterior portion of the tumour being treated by diathermy. At the end of the operation the parts are brought together by sutures. In carcinoma of the cheek the glands are seldom affected until late in the disease. Where they are involved, removal must be undertaken by the ordinary method of dissection.

The *after-treatment* of these cases is rather important, as there is, of course, a tendency to contraction and limitation in opening the mouth. It is, therefore, necessary as soon as the skin wound is soundly healed periodically to employ means which will cause stretching of the cheek. The patient may wear a prop during part of the day between the teeth or gums, and it may be desirable forcibly to open the mouth on one or more occasions under gas anæsthesia.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT EDINBURGH.

(*Concluded from p. 663.*)

SECTION OF TUBERCULOSIS.

THIS Section, which met on Friday, July 22nd, under the presidency of Dr. S. VERE PEARSON (Mundesley), discussed three large topics.

Radiology and Diagnosis of Intrathoracic Tuberculosis.

The opening paper giving the specialist's viewpoint was read by Mr. H. MORRISTON DAVIES (Vale of Clwyd Sanatorium), who pointed out that the diagnosis of pulmonary tuberculosis was not merely a matter of recognising the presence of the disease, although both the recognition of it and the differential diagnosis were of great importance and often a matter of great difficulty. Diagnosis must necessarily include the character as well as the type of disease. They must know, for example, whether it was acute miliary, acute pneumonic, acute ulcerative, or chronic; to what extent the changes due to the tubercle bacillus predominated, or were complicated or overshadowed by those due to the secondary organisms; and what part was played by the mechanical changes. It was also imperative to know the anatomical extent of the lesions, especially when there was any question of surgical intervention.

The symptoms and signs of the disease varied in every case, some cases showing but one symptom, such as lassitude or hæmorrhage, and no sign other than harsh breath sounds. Symptoms such as cough and sputum might be absent for years from the clinical picture, while pyrexia might be an early or a late manifestation. Physical signs might be difficult both to ascertain and to interpret. Some patients seemed incapable of using their chest or diaphragm so as to make even the normal breath sounds audible through the stethoscope, other difficulties being that there was practically no symptom and no sign that could not be produced at one time or another by long intrathoracic disease, and that breath sounds could be heard through even a considerable layer of fluid. It was important, therefore, in all cases to check, control, and correct the clinical findings by the radiological ones. Although clinical examination was the most important of all methods of investigation, there was much that could only be revealed by radiology, more especially in cases in which the pleural cavity was the seat of the lesion or in which it was involved secondarily to the disease in the lung. Radiology had taught them a great deal about pulmonary tuberculosis; it had corrected the belief that used to be held that tuberculosis started most commonly at the apex of the lung; it had taught them the limitations of the movements of the domes of the diaphragm; it had shown them how frequently the disease was more extensive than was suggested by the clinical findings, and, conversely, how occasionally the disease was much more limited than was suspected, owing to the widespread changes in the physical signs caused by local changes in the larger bronchi. Unfortunately, radiology had also to some extent confused them by demonstrating the shadows known as "pleural rings" and those changes at the root of the lung which had given birth to the term "hilum tuberculosis."

The cases that came before them for diagnosis belonged to two groups: the one with few symptoms, in which the existence of pulmonary disease had to be determined, and the group with well-marked symptoms and signs, in which the character of the disease had to be diagnosed. The great majority of the first group consisted of children and young adults, and the commonest symptoms were cough, which had persisted since a cold or an acute specific illness (especially measles and whooping-cough), lassitude, poor development, and dyspnœa. Occasionally in the more advanced cases there was cyanosis. The physical signs usually consisted of impaired resonance, deficient air entry, and some moist sounds. A number of these cases were labelled hilum (or pulmonary) tuberculosis, some being treated as such and bearing the stigma for the rest of their lives. It was here that radiology, with increasing knowledge, would prove of immense benefit. The great difficulty lay in the inability to establish just when the hilum shadow ceased to be normal, and what were the characteristics of early disease as opposed to chronic irritation. It was well known that an impure atmosphere led to increase in density in shadows, that chronic irritation caused enlargement of glands and increased striation, and that in some cases, especially after bronchitis, broncho-pneumonia, and in association with chronically enlarged tonsils, such changes might be very striking. Two things had struck him in X raying a large number of apparently healthy medical students 16 years ago: the enormous variations that occurred in the so-called normal subject (only one of the students had subsequently developed tuberculosis, and his original radiogram had shown nothing striking); and the fact that the traction of the heart to the left with a normal-looking lung and pleura was invariably due to a basal pneumonia in the past. He agreed with Dr. Agassiz that radiology was of the utmost importance in differentiating a non-tuberculous fibrosis from other affections of the lungs. He himself had had many cases sent to him as suffering from pulmonary tuberculosis who were suffering from some other disease—in a large proportion of cases from bronchiectasis. In the majority of these cases radiological examination would settle the diagnosis, although there were some very old-standing cases where the secondary bronchiectatic changes associated with chronic bronchitis were so predominant that it was hard to differentiate between them and a non-tuberculous bronchiectasis. A less frequent mistake was to label cases of malignant disease and of syphilis as cases of tuberculosis. In most of these cases an X ray photograph would have obviated the error. When they turned to the pleural and mediastinal cases the importance of radiology became even greater. An interlobar effusion might be suspected, but it was rarely more than a guess until confirmed by the X rays, while the difficulty was even greater in cases of mediastinal effusion. In the diagnosis of activity of a tuberculous lesion it was the clinical signs and not radiology which had to be relied on, though information could also be obtained from the latter source also. The snow-flake fluffy shadow of an acute lesion was in striking contrast to the denser, sharply defined outline of the fibrotic lesion. At times there was a great temptation to diagnose on clinical examination the presence of a cavity when the radiogram showed that the signs were due to a dense area of fibrosis contiguous with a large bronchus. Occasionally the radiogram would reveal a cavity in the centre of a densely fibrotic area which was unsuspected from clinical examination. The X rays would, moreover, reveal in a large cavity the efficiency or otherwise of such a cavity, and any retained products that might be present. When the case under investigation was one with an effusion or pneumothorax, or a combination of the two, it might be impossible to obtain by clinical examination any idea of the extent of the collapse or the character of the collapsed part of the lung. If on examination a patient was found to have a pleural effusion, it was not sufficient to be content with that as a diagnosis; it was necessary to know the cause of the effusion. It might be failing heart or kidney, trauma, suppuration above or below the diaphragm, an infection, or granuloma inside the pleural cavity or in the lung. It might be secondary to an inflammatory lesion, such as pneumonia, or to carcinoma. It might be primary tuberculosis of the pleura, or secondary to pulmonary tuberculosis. The diagnosis might be easy or it might be extremely difficult, especially if the primary lesion was in a collapsed lung surrounded by liquid. But if the liquid was replaced by air and the collapsed lung partially re-expanded, it became possible, by

radiology, to see the character of the lesion which was primarily responsible.

Precision in diagnosis was essential for determining prognosis and treatment; it was absolutely imperative before any surgical treatment could be considered. To attempt treatment of a case of pulmonary tuberculosis by operative intervention without the most thorough radiological as well as clinical examination was to make the patient run a serious risk. In those cases it was not so much the precise condition of the more affected side, but the character and extent of the lesion in the sound lung which was so important. The value of a radiogram lay in its clarity and in their power to interpret it. An indifferent radiogram might be not only worthless but a source of danger, as they might fail to detect the existence of important lesions, and act on the erroneous idea that they were not present.

The question of the interpretation of the film brought them to one of the most difficult problems. The radiologist who handled hundreds of films could detect abnormalities and describe the shadows far better than the average medical man, but his opportunities for studying the radiogram and the clinical picture side by side and following the development of the case were limited. The physician who specialised in pleuro-pulmonary diseases had very great experience, but it was possibly somewhat less than that of the radiologist, while he was also less aware of the allowance to be made for imperfect exposure or development. He had, however, the advantage of his knowledge of the clinical side. The general practitioner, with the wide range of knowledge required of him, could not be expected to have a thorough understanding of the interpretation of radiograms, and he should, in all obscure cases, call in a specialist or consultant and a radiologist. A frequent cause of delay before patients applied for sanatorium treatment was wrong diagnosis, and in order to obviate this he urged that an invariable rule should be made that when there had been persistence for more than three months of symptoms which might be due to tuberculosis, any sputum present should be examined and a radiogram taken.

Dr. E. RIST (Paris), who followed, emphasised the importance of X rays in correcting physical signs. This was best seen in cases in which there was a deep-seated cavity near the hilum, but even superficial cavities were sometimes absolutely silent to the stethoscope. In pneumothorax work X rays were often helpful in deciding whether the signs heard in the less affected lung were an indication that it, too, was affected, or whether the sounds were merely transmitted from the worse lung. Dr. Rist thought that many cases suitable for pneumothorax had not had the benefit of this treatment owing to the failure of the physician to make use of X rays to assist him on this point. He concluded with a plea for more X ray screen examinations, which had the advantage of showing movement, and should always precede the taking of a film. No chest could now be said to have been properly examined unless a screen examination had been made. Objections on the ground of expense should be met by the reply that there was a time when physicians said they could not afford stethoscopes.

Dr. J. LOGAN STEWART (Manchester) considered that the term "hilum tuberculosis" was far too widely used. It should be dropped as misleading in all cases in which lung tissue was affected; and where the disease was confined to bronchial glands the appropriate name should be used. He showed a number of slides to illustrate the various types of case in which an increase of the hilar shadows was noted. A sharp distinction was drawn between cases in which the adjacent lung was infiltrated and those in which it was not. In the latter class plates were shown in which the heavy shadows were due to pleural thickening over the root of the lung, to interlobar pleurisy, and to vascular congestion in cases of mitral disease.

Dr. J. M. WOODBURN MORISON (Edinburgh), speaking as a radiologist with experience of general practice, considered X rays to be an integral part of the physical examination. A diagnosis on the strength of an X ray examination alone should, however, never be made; and the custom adopted by some specialists of sending a patient to a radiologist with a card marked "X ray of chest, please," was not to be recommended. To illustrate this point three slides were shown, in all of which a very similar picture was given, but which were taken from cases of hydro-pneumothorax, subphrenic abscess, and diaphragmatic hernia.

Dr. C. P. LAPAGE (Manchester) considered fibrosis of the root of the lung to be a common condition in childhood; in these cases the most important function of the physician was to determine whether or not the disease was active. The speaker looked upon loss of tone of the skin between the scapulæ as a useful indication of toxæmia in these cases.

Dr. L. D. PARSONS (Ceylon) advocated the use of tuberculin tests in the diagnosis of early tuberculosis.

Mr. DAVIES, winding up the discussion, agreed with Dr. Rist as to the importance of fluoroscopy, and with Dr. Morison that all doctors engaged in chest work should have some knowledge of radiology. He feared, however, that too much emphasis on X ray signs might result in the neglect of the more important clinical side, which should always come first.

Pathology of the Tuberculosis of Childhood.

Prof. EUGENE L. OPIE began by discussing the question of latent tuberculosis. By this term he did not mean that the disease was dormant or arrested, but merely that it gave no symptoms or signs which could be detected by patient or physician. A comparison was made between latent and open tuberculosis on the one hand and uncomplicated measles and measles followed by pneumonia on the other—a striking illustration of the importance of early diagnosis and treatment. Attention was called to the fact that in children the disease progressed more in the lymphatic glands than in the lung parenchyma. Although bronchial gland tuberculosis was often associated with infection of the lung tissue adjacent, a primary focus could usually be found in the part of the lung drained by the affected gland. Prof. Opie also recalled the fact that when there was a focal lesion of the lung the mesenteric glands were rarely affected, and vice versa, and referred to the curious and inexplicable way in which adult phthisis tended to affect the apex of the lung, in which respect it was in sharp contrast with childhood tuberculosis and animal tuberculosis. Although the adult lesion tended to be chronic it remained confined to the lung for a long time, and for some unexplained reason the lymph glands were usually unaffected. The speaker ended by giving some statistics to illustrate the high incidence of latent tuberculosis in the children of tuberculous parents.

Dr. R. G. CANTI (London) discussed some of the theories as to the path of infection in tuberculosis, based on his observations in more than eighty autopsies on children suffering from intrathoracic tuberculosis. He considered mediastinal infection to be almost invariably secondary to a pulmonary focus, the following reasons being given in support of this view: (1) the glands were involved whenever there was tubercle of the lung; (2) when the glands were affected a focus could usually be found in the lung; (3) the glands which were involved were those which might be expected to be so if the pulmonary focus were primary. The path of infection through the mesenteric glands to the lung was unlikely because these glands were rarely affected in lung cases. The suggestion that bacilli of human type passed through the glands and affected the lung was not tenable, because these glands were just as easily affected by the human as by the bovine bacillus.

Dr. P. F. ARMAND-DELILLE (Paris) showed an interesting series of post-mortem specimens and compared them with X ray plates of the same cases taken a few days before death. The accuracy of the comparison was increased by the speaker's method of hardening the inflated lung in a cast of the chest wall

before cutting sections. The chief point brought out by these observations was that only a small part of the periphery of the hilar region was visible on the X ray plate, the greater part being hidden by the heart. Prof. Opie, in replying, referred to the unexpected opposition to the views he had expressed as to the pulmonary origin of bronchial gland tuberculosis, and recalled that Parrot and Kuss had both described these primary foci before Ghon, and their work had been acknowledged by him.

Interrelation of Physician and Surgeon in Non-pulmonary Tuberculosis.

Dr. D. A. POWELL (Cardiff) opened the third discussion. In non-pulmonary as in pulmonary tuberculosis, he said, the physician and surgeon should be one and the same individual for all purposes of diagnosis and treatment, except those involving major operations or a few highly technical procedures. The tuberculosis officer, to attain this end, should seize every opportunity to train himself to become a competent surgeon, first, by looking upon a period of residence in a surgical tuberculosis or orthopædic hospital as quite as essential a part of his training as residence in a chest hospital or sanatorium; and, secondly, by close linking up of his area surgical work with that of an institution, frequent reciprocal visits and interchange of medical staff being an essential part of the scheme. The speaker believed that in this way the present unfortunate tendency to divorce the conception of tuberculosis of bones and joints from general tuberculosis would be checked. Tuberculosis, whatever its site, was the same pathological process, diagnosed by the same procedures, and treated on the same principles; and he urged that the mere utilisation of methods of treatment similar to those of orthopædics should not blind them to the fact that the essential element in the successful management of cases was a sound knowledge of the disease as a whole, fortified by manual dexterity and reinforced when required by the operative skill and expert knowledge of the general or orthopædic surgeon. Among the definite advantages that would accrue if this unification or closer interrelation could be carried out would be the addition of some much-needed precision to their diagnostic criteria, especially in tuberculosis of glands, and their recommendations for treatment would be based on fact rather than on prophecy. By refraining from making up their minds as to the diagnosis until there was a practical certainty about it, they would obviate, in a large proportion of cases, the mental trauma they so lightly inflicted upon their patients to-day, and would avoid the finality of notification with its consequences. The speaker took, as an instance, tuberculous glands, and pointed out that if the tuberculosis officer or his residential colleague became the surgeon oftener and earlier and excised doubtful glands for examination, their ideas as to the distinction between tuberculous and non-tuberculous glands would be clarified, and they would also realise more clearly that although it was broadly true that a tuberculous lesion was the local manifestation of a general infection, yet that in cervical adenitis both lesion and infection might be localised, accessible, and suitable for eradication.

Few problems in medicine required nicer judgment or greater patience than to decide in bone and joint cases when the disease was quiescent and treatment could be altered, or when the disease was arrested and treatment could be discontinued. In early lung involvement the issue was usually clear-cut—namely, the presence or absence of tuberculosis; in non-pulmonary tuberculosis this issue was complicated by the necessity in addition of differentiating between tuberculosis and a number of conditions which might closely simulate it. As a general rule, tuberculosis officers should content themselves with a provisional diagnosis and *act upon it*. Until tuberculosis officers were physicians and surgeons too they must follow up a preliminary, provisional, or approximate diagnosis by such action as requiring the attendance of the patient at a clinic or his admission to hospital, where the differential diagnosis could be elucidated without detriment to the patient, and where treatment could be initiated without loss of time. By a closer coöperation or unification there would be, among other advantages, a more general recognition of the fact that in associated pulmonary and non-pulmonary disease premature success in arresting the local lesion (especially if the former were the primary manifestation) might even activate or reactivate the trouble in the lung. It would be remembered also that, while the development of secondary deformities was a reproach, caution in attempts at preventing or correcting the primary deformity might not be too high a price to pay for life. The surgeon's association with the tuberculosis officer would enable him to realise more vividly the economic repercussion in adult patients of his occasionally too conservative methods in some lesions of the lower limb. He would also realise that after-care in tuberculosis, as opposed to orthopædics, was more than a medical problem, and connoted much more than the correct use of appliances; that failure was not necessarily due to indifference or carelessness, but to those social and economic disabilities that exerted such a profound effect upon the prognosis of tuberculosis in any form.

Prof. JOHN FRASER (Edinburgh) said that the treatment of tuberculosis might be considered under five headings: (1) excision of the lesion; (2) stimulation of the organism by general treatment; (3) rest—the basis of all treatment; (4) chemotherapy, from which nothing of proved value had resulted; (5) tuberculin. This last was criticised in that it caused an increase in the blood-supply to the affected part, whereas Nature's way of healing involved a diminution of blood-supply, following endarteritis obliterans. Prof. Fraser summed up by saying that if the part were put at rest, Nature would supply the fibrous tissue.

Mr. G. H. GIRDLESTONE (Oxford) deprecated the tendency for the tuberculous cripple to be separated from other cripples, and advocated a national scheme to deal with all bone and joint cases requiring hospital observation and treatment. He considered that there was danger of the non-tuberculous cripple being overlooked unless he was treated by the same organisation that was caring for the tuberculous cases. Far from being an appendage of orthopædics, the tuberculous cases formed the majority of those treated in orthopædic hospitals.

In his reply Dr. POWELL stated that he favoured coöperation rather than amalgamation in the treatment of tuberculous and non-tuberculous cripples.

In the afternoon Dr. ARMAND-DELILLE and Prof. OPIE each showed a series of slides to illustrate the papers they had read in the morning.

SECTION OF TROPICAL DISEASES.

WEDNESDAY, JULY 20TH.

ABOUT 85 persons were present on Wednesday, July 20th, when the President, Dr. ANDREW BALFOUR, opened the Section and recalled that on the last occasion on which the Association met in Edinburgh Sir Patrick Manson announced Sir Ronald Ross's discoveries regarding malaria, and reminded his hearers that those discoveries marked the beginning of a new era in tropical medicine.

Recent Advances in the Treatment of Amœbic Dysentery.

Dr. P. H. MANSON-BAHR (London), who read a paper by himself and Dr. E. G. SAYERS, said that ipecacuanha powder by the mouth and emetine injections had both been found unsatisfactory as a means of eradicating amœbic infection, but the use of emetine-bismuth-iodide, in powder form in gelatin capsules, had proved a distinct step forward. For lasting results a dosage of 36 gr. spread over 12 nights was required along with dietetic restrictions. He quoted some striking cases where this treatment had brought about permanent cure, and as a general rule the more acute the symptoms the more satisfactory and

lasting were the results. Out of 40 cases treated in the last seven years there were five in which the drug had not effected permanent cure. Results from the use of emetine periodide (12 g. per diem) during the same period were less favourable, 5 out of 12 so treated having relapsed almost immediately. The introduction of yatren marked a further advance. This compound of oxyquinoline-sulphonic acid and iodine could be given by the mouth in doses of 24 gr. daily, or could be injected into the rectum in a strength of 2½ per cent. A study of four acute cases treated by this drug showed that it brought about rapid improvement in the patients' symptoms, but did not always eradicate the infection. The experiences described led to the conclusion that in the combination of yatren and emetine-bismuth-iodide (E.B.I.) there lay the greatest possibilities of rapid alleviation and permanent cure. The E.B.I. is given by the mouth in 3 gr. doses for ten nights while by day the patient receives the yatren solution into the rectum. A combination of these two drugs was particularly well tolerated, so that it has been possible to record a series of 22 cases, many of them most intractable and resistant, successfully treated without, as yet, any relapse, although the series included no case which had not been observed over a period of nine months since the cessation of treatment.

In a series of water-colour illustrations (presented by epidiascope) Dr. Manson-Bahr demonstrated the appearances of various amœbic lesions as observed through the sigmoidoscope and the effects of various treatments upon the lesions. The most acute lesions rapidly subsided and healed so that, after ten days of treatment, all that could be observed were small pits or depressions to mark the site of former lesions. These depressions, often microscopic in size, were also seen in "carrier cases" and in the latent or chronic forms of the disease.

Prof. CHARLES A. KOFOID (California) said that laboratory findings in over 4000 cases of infection by *Entamœba histolytica* during the past nine years confirmed the greater efficiency of E.B.I. and emetine periodide as compared with emetine, yatren, and stovarsol; the last two were reported to be useful as adjuvants although neo-arsphenamine was replacing stovarsol with advantage. To establish a negative diagnosis examination of repeated series of six consecutive stools was necessary. He relied for diagnosis primarily upon the finding of cysts and the nuclear structure of matured cysts; and some difficulty might be met in distinguishing between the motile phases of *E. histolytica* and those of other amœbæ found in human stools. He had been observing an amœba, found in stools, which resembled the largest "race" of *E. histolytica*, and was generally present in the 4-nucleate stage in stools, and had clear pseudopodia in the motile phase. Nearly 100 cases of this infection had been observed among 2578 persons examined. In culture this amœba had maintained its characteristic morphology and behaviour, in one instance for over a year. The characteristics were sharp distinction between clear ectoplasm and granular endoplasm; cysts with 1, 2, 4, and occasionally 8 nuclei; freedom in budding in fresh stools, and, most diagnostic, a single large lateral blob of peripheral chromatin on the nuclear membrane, and the presence of eight chromosomes at nuclear division. The name *Councilmania dissimilis* had been given to this amœba, whose pathogenicity or harmlessness was as yet uncertain.

A paper embodying their investigations was presented by Prof. WARRINGTON YORKE and Dr. A. R. D. ADAMS (Liverpool).

Life-history of Entamœba Histolytica.

In their work they found that cysts of *E. histolytica* develop and hatch under suitable conditions in vitro; moisture and a temperature of about 37° C. were essential for excystation, but the passage of cysts through liquor pepticus or liquor pancreaticus was unnecessary for that purpose. They had devised a method of preparing, from fæces, washed concentrated suspensions of cysts. When such suspensions were inoculated on Locke egg-serum medium the youngest cysts were found to be uninucleate and loaded with glycogen. With development chromatoid bodies appeared, nuclei divided, and glycogen decreased. These processes continued and when the cyst was completely mature and ready to excyst the nuclei were agglomerated, cytoplasm homogeneous and without glycogen, and the chromatoid bodies greatly reduced or absent. They had observed no evidence of autogamy in cyst development, but frequently had seen chromatin particles apparently extruded from nuclei immediately prior to or during division. The freshly excysted *E. histolytica* contained four closely agglomerated nuclei, and the cytoplasm was very firmly alveolar. Its movement was characteristically slug-like, nuclei almost invariably anterior, and a more or less motionless tail was dragged behind. In cultures most 4-nucleate excysted amœbæ divided, directly or indirectly into four uninucleate individuals, but sometimes multinucleate individuals are formed.

They could not confirm Dobell and Laidlaw's statement that recently passed cysts did not hatch or develop further until cooled outside the body for one or two days; nor the same workers' statement that immature cysts are killed by cooling outside the body. In their experience cooling cysts for periods up to one or two days had no appreciable effect and was unnecessary for further development and excystation. They found the cysts to be killed within five minutes by a temperature of 50° C.; to be resistant to emetine and yatren, and relatively so to hydrochloric acid and chlorine, but they were quickly destroyed by phenol disinfectants, formalin, and perchloride. The cysts survived only 7–10 days in fæces at laboratory temperature and only slightly longer at 0° C.; even when washed free from fæces and stored at 0° C. they survived only two or three weeks.

The life of the cysts in man's intestine was short; development from precystic stage to mature quadrinucleate cyst proceeded rapidly and steadily, and was complete in a few hours. This explained the fact that cysts passed by the same person at different times were often at varied stages of development. Mature cysts probably died if they did not escape from the bowel in, at most, 48 hours. Excystation did not take place in fæces or in extracts of fæces in Locke serum in vitro. From this fact and because prolonged search has failed to reveal typical excysted amœbæ in stools, they concluded that excystation of *E. histolytica* cysts did not take place in the bowel in which they were formed, and that the hypothesis of Sellards and Theiler, that relapses in amœbic dysentery may partly be due to excystation of cysts long stored in the bowel was incorrect.

Problems of Malaria Prophylaxis.

To introduce this discussion copies were distributed of an article by R. Hegner setting out 40 points with regard to malaria in which knowledge is lacking or incomplete. In opening the discussion Lieut.-Colonel S. P. JAMES (Ministry of Health) based his remarks on the findings of the Malaria Commission of the League of Nations, published in that Commission's second report, in the drawing up of which Colonel James assisted. He said that two limitations applied to the recommendations of that report; first, they were applicable to European countries; and, secondly, to countries who could undertake only a moderate expenditure. As a rule the Commission's recommendations represented a compromise, the various members endeavouring to arrive at what might be called the "average opinion." In his view present knowledge and resources rendered it necessary to restrict the aim to "scotching of the enemy"; eradication was as yet unattainable. The Commission had laid stress upon the fact, often overlooked, that there are methods of dealing with malaria which have proved effective apart altogether from the knowledge of the transmission of the disease by mosquitoes, and there was no one method of malaria control which could be described as superior to all others, and therefore to be universally adopted. Malaria control

was essentially a *local problem* requiring preliminary local examination before plans were framed. The Commission considered that it was advisable to limit the methods adopted to one or two well-tried operations rather than to put in action simultaneously a large number of methods reported successful elsewhere. Malaria control measures were often classified as direct and indirect, and the Commission had employed the term direct in a very strict sense—namely, as properly applying only to the killing of the plasmodium either in man or in the mosquito. General antilarval measures were classed as indirect. Certain direct methods were called "primary measures," were concerned with infected persons and the interior of their dwellings, and were indispensable. Treatment of cases, adequate and gratuitous provision of quinine, and arrangements for diagnosis were of first importance; inspection of school-children, following-up of patients to their homes and house-to-house inquiries might be undertaken by duly qualified health visitors. The Commission also recommended as a "primary measure" the systematic killing of adult female anopheles in the interior of dwellings; it was preferable that householders themselves should be educated to undertake this duty. Regarding places where the economic position and social status of the people made these primary measures impossible, nothing save the free distribution of quinine could be attempted until permanent settlement of the land and a fair standard of housing and living had been brought about. It was striking that on some plantations extensive drainage and antilarval works had been undertaken without lessening of malaria among the labourers, who continued to be badly paid and poorly housed. The terms "bonification" and "assainissement" were often misunderstood. The benefit of drainage was often through improved agricultural and economic conditions rather than through reduction of mosquito breeding-places. The continuing of scientific research was most important. The Commission recommended stations for epidemiological observations over a number of years, and laboratories (in countries employing malaria therapeutically) where pure strains of malaria might be cultivated in mosquitoes. Such laboratories established in organised hospitals would provide opportunity to study clinical and parasitological features of malaria and the action of quinine and other drugs which might be introduced.

Lieut.-Colonel E. D. W. GREIG (Edinburgh) described his study of 18 cases of intentionally induced malaria. Well-marked differences of individual susceptibility were observed; if a practical test for the detection of degree of susceptibility could be devised it would assist in prophylaxis. He outlined the problems which present themselves in connexion with the latency (incubation period) of malaria, the time of appearance of sexual forms of the plasmodium, and the uncertainty whether the malaria parasite produces a toxin, and illustrated his remarks by lantern slides of temperature charts.

Dr. MANSON-BAHR gave an account of his employment of plasmochin and plasmochin compound in treatment of malaria. The selective action of this drug for the sexual forms of the parasite made it valuable for prevention of spread of the disease.

Prof. MARTINI (Hamburg) thought there was a danger that Governments would interpret the Malaria Commission's report as sanction for their doing nothing but provide quinine. He leant towards the employment of thorough antilarval measures. He gave an account of his malaria studies in South Russia and Asia Minor, and stated his opinion that cases of so-called spring malaria are nearly always relapses of infections of the previous autumn. He had successfully based his plans for personal prophylaxis in this belief, neglecting precautions in the spring-time.

Dr. L. W. HACKETT (Rome) gave interesting particulars of the use of Paris green as a larvicide in the work of the International Health Board in Italy.

Dr. DRBOHLAV told of malaria in Czecho-Slovakia, and Colonel JAMES summed up the discussion and replied to some questions.

SECTION OF THE HISTORY OF MEDICINE.

AT the first meeting of this new Section, held on July 22nd, the President, Dr. J. D. COMRIE (Edinburgh), hoped that the chief aim would be to treat the history of medicine as a subject of living interest. He was strongly of opinion that it should form part of the medical curriculum.

The Evolution of Disease.

Sir HUMPHRY ROLLESTON (Cambridge), opening a discussion on this subject, said that W. P. Alison was convinced of a change in the types of disease in the course of the first 30 years of the nineteenth century, but the supposed change from sthenic to asthenic type was attributed emphatically by Hughes Bennett to the effect of treatment rather than to any inherent alteration in disease. The science of palæopathology, by the study of morbid anatomy in the fossil remains of man and animals of 500,000 years ago, notably the work of R. L. Moodie in America and of M. A. Ruffer Fouquet, Elliot Smith, and Wood Jones in the investigation of mummies in Egypt, had yielded a considerable amount of valuable information as to the existence in ancient times of conditions of modern disease, recognisable even at great lengths of time. These included arteriosclerosis, rheumatoid arthritis, gout, pyorrhœa, hydrocephalus, pneumonia, anthracosis, cirrhosis of the liver, and peri-appendicular adhesions. Achondroplasia was not uncommon in ancient times, for, besides the skeleton remains of achondroplasics (e.g., in the Tomb of Senab, 2900 B.C.), mural paintings and sculptures of 5000 years ago showed evidence of the disease in figures of the Egyptian gods, Ptah and Bes, and in those of the dwarfs of ancient Egypt, chiefly among males, as also, at a much later date, did figures of court attendants in paintings by Velasquez and others. The pigmies, regarded by Pierre Marie as achondroplasic, were not really so, but were probably as much a racial variation in ancient times as those now known in the forests of Central Africa. Pott's disease of the spine and steatopygia, a gluteal overgrowth of the adipose tissue, as in the Hottentot Venus, had also been reproduced in statuettes by the Egyptian sculptor. Berkeley Moynihan had recognised in a bust done of Alexander the Great in his fatal illness the manifestations of cerebro-spinal fever. It had been possible to identify rickets as well as achondroplasia in remains from Herculaneum and Pompeii, but no evidence of rickets had been found in Ancient Egypt, nor of authenticated syphilis as had been claimed, for Elliot Smith had shown that the supposed syphilitic bone changes were due to the erosion of human remains by beetles, long after burial.

Tuberculosis had been recognised in Egyptian mummies, and in the pulmonary form was probably common also in ancient Greece, where also mumps was apparently definitely known, and with its complication, orchitis, had been described by Hippocrates. Ancient votive offerings of patients seeking cure from their deities showed attempts at reproducing their particular complaint. Although certain conditions of disease were not known to the medical profession till a much later date, their existence long previously had been portrayed by old artists, as example, the portrait of Frederick I. of Prussia by Lucas Van Leyden in 1521, reproduced by Semon, which showed the typical adenoid facies; yet it was only in 1868 that William Meyer, of Copenhagen, first described adenoids to the profession. The dancing mania prevalent in the fourteenth to the sixteenth centuries and variously called the dance of St. Guy, St. John, St. Anthony, and St. Vitus, had been identified from old relics, and in Raphael's paintings, as hystero-epilepsy. From the written records of diseases occurring in the past—e.g., leprosy and hydrophobia—though far more numerous than pictures and drawings, it was more difficult to recognise their true character and to decide as to a change in type, as the description possibly covered more than one disease occurring at the same time. The designation "lepra" probably

included not only true leprosy, but also pellagra, lupus, syphilitic, and other skin lesions.

Disease was the reaction of a complex organism to various influences, and the changes in social conditions brought about by famine, war, and overcrowding had more effect on the spread and type of acute than chronic disease, but alterations of the former were more difficult to determine. The change from the cave man to the club man was a very considerable one, spread over a period of ages, whereas the transformation of lowly organisms occurred with far greater rapidity than in the higher animals. It was probable that alterations in the virus were of more importance in bringing about a changed type of disease than alterations in the host. Small-pox and scarlet fever provided examples of changes in the virus resulting in asthenic types of those diseases, as common at the present day. Alteration in the character of the soil and seed might bring about a new disease, or be responsible for the waxing and waning of the original manifestations of a disease, which at the present day had led to so much separation and differentiation of the various types of infection. In the case of typhus, probably the famine fever of ancient Greece, and not till the nineteenth century differentiated from typhoid fever, was it possible that typhoid and paratyphoid fevers had been originally evolved from it, although now clearly recognised as distinct? Chicken-pox and vaccinia might reasonably be regarded as belonging to the same stock as small-pox, yet their differentiation had become essential, and even alastrim, modified or para-smallpox, was held by some to be an entirely separate disease from true small-pox, which until Sydenham's time was confused with hæmorrhagic measles. There was, however, evidence as far back as 1100 B.C. of an eruption like small-pox, which had been identified in an Egyptian mummy of that period.

The influence also of secondary infections on the type of disease had caused much confusion as to the primary cause. Particularly was this the case with influenza, in which the hæmolytic streptococcus had played so important a part in recent epidemics. The evolution of the streptococcus was possibly correlated with the variety in the types of streptococcal infection recognised at the present day, and its presence as a secondary infection had been held by some to account for the severe form of small-pox. Influenza had been claimed by Sir W. Hamer, F. G. Crookshank, and J. T. C. Nash to have occurred in the past under the name of sweating sickness, and again in Picardy in 1886. No fewer than 194 epidemics had been recorded by Hirsch in France between 1714 and 1874, as compared with only five in England in the fifteenth and sixteenth centuries. Chantemesse held that these outbreaks were distinct from true influenza, contrary to Hamer's opinion, which embraced also cerebro-spinal fever, encephalitis lethargica, and dengue as influenzal manifestations. The spread of disease had been productive of great national crises; for example, to the prevalence of malaria had been attributed the decadence of Greece and Rome. The clinical resemblances of the disease, past and present, as derived from contemporary literature, left little doubt that malaria was prevalent in Greece from the fourth century B.C. and in Italy from 200 B.C.

Bubonic plague was a disease which may have been known well before the Christian era. It was conjectured to have attacked the Philistines severely after their capture from the Israelites of the Ark of the Covenant, and was probably symbolised in the gold offerings (representing the tumours or emerods from which survivors had suffered, and the mice, as supposed carriers of infection) which were made in propitiation when the Ark was returned. Apart from that biblical record, the earliest reliable diagnostic account had shown plague to have appeared in Egypt, Libya, and Syria in the third century B.C. Later, in A.D. 70, Aretæus had mentioned pestilential bubo, but the history of the disease could be more confidently traced from the great plague of Justinian, which came from Egypt in A.D. 542 and overran Europe. The term "plague" had been one of wide application and it was probable that the plague of Athens, described in 430 B.C. by Thucydides and Diodorus Siculus, included diseases as widely separated as malignant scarlet fever, small-pox, and typhus. Similarly the pestilence in Rome, known as the Antonine or Long Plague of A.D. 165, of 15 years' duration, had been variously identified as dysentery, small-pox, and typhus, and was possibly a succession or conglomeration of different diseases.

The history of diphtheria had demonstrated the difficulty of distinguishing between the various severe forms of throat infection and what was now recognised as clinical diphtheria. Adami had held that the true diphtheria bacillus represented a change in type of the harmless diphtheroid variety, and that the transformation had shortly preceded Bretonneau's classic account of the disease in 1821. Appendicitis, so common at the present day, could be described as a modern disease, for at the beginning of the nineteenth century Parkinson and Addison regarded it as a rare condition. Had it not been so, there was no doubt that many more people would have died from it for want of operation. However, detailed descriptions certainly existed earlier than that of Fitz, of Boston, in 1886.

It was only in the sixteenth century that gout and rheumatoid arthritis had been distinguished, yet evidence of chronic arthritis had been found in neolithic skeletons and in ancient Egypt. Jeanselme, in his study of gout in Byzantium, was of opinion that six out of 24 sultans between the fourteenth and seventeenth centuries had suffered from gout.

The incidence of aneurysm, particularly of the popliteal artery, which was known in the fifteenth century, and its relation to syphilis at that period, drew attention to the disputed origin of syphilis, whether brought from South America by the crews of Columbus' expeditions, or, as some held, long known in Europe in a mild concealed form and transferred to the virgin soil of newly discovered America, there to develop in epidemic and virulent form. The Great War, however, had shown the importance of trauma as the chief cause of popliteal aneurysm, although now become a rarity, possibly attributable to changes in occupation, riding having been largely replaced by motoring.

Dr. G. M. CULLEN (Edinburgh) in a paper on

World Epidemics

and their relationship in cause and effect on social conditions, referred to the too frequent perversion of history to the point of view of the propagandist and partisan. By the influence of the individual, too great significance became attached to individual ideas, resulting, in the case of one medical biographer, in concentration on one idea—e.g., that all patients were suffering from eye-strain due to mild astigmatism, or, among the followers of psycho-analysis, that every patient was afflicted with some form of insanity. It was curious to note that, on the other hand, so important a subject as the influence of great epidemics—e.g., the black death—on the history of a people or nation had been much overlooked. Even in the works of Hume and Green the aftermaths of past epidemics had received little or no notice. Now, however, those effects were being better studied, thanks to the researches of W. H. S. Jones and others on the influence of malaria on Greek history.

Dr. Cullen drew attention to the outstanding importance of three dates in the history of civilisation: (1) 430 B.C., when Greece was at the zenith of her power. A hundred years later came her decline and eclipse by the conquests of Alexander the Great. (2) A.D. 542, the Justinian period. Within a century the Arabs had ravaged the Roman empire. (3) A.D. 1348. In 1358 the Turks set foot in Gallipoli and effected the conquest of Constantinople. It was significant that each of these dates, when the respective

nations held world-wide sway, marked the development of widespread epidemics, the first, malaria, the second, plague, and the third the black death, the results of which had effectively prepared the way for conquest by loss of life and the flight of citizens from the stricken towns, which had been more marked in civilised communities. Following the depopulation caused by the black death in 1348, efforts were made to attract fresh inhabitants to the cities, which consequently rose in importance and prosperity. There followed confederations such as the Hansa league of towns, which marked the downfall of the feudal system owing to the weakened power of the nobles. The protection of the king was afforded to towns against the nobles, until power became concentrated under one rule, and by the end of the fifteenth century the kings of England, France, and Spain had become absolute monarchs. Pestilence first enlisted the labourers against the army of capitalism, and in France, for instance, led to the rising of the Jacquerie. There resulted the breaking down of social distinctions, so obviously lacking in death, and it was then the saying originated "When Adam delved and Eve span, who was then the gentleman?" The real birth of the middle-classes belonged to that period, and the rapid change of hands of unaccustomed wealth led to reckless prodigality and many alterations in social customs and dress. In no direction, perhaps, was the effect of the black death more marked than in regard to religion and in the sense of dependence on the Almighty. Moreover, the heavy mortality among priests was regarded as due to divine visitation, and it was only the survivors who were judged to have been fit to administer sacrament. Efforts to fill up the losses in the priesthood failed or attracted only those least fitted.

Dr. Cullen concluded by drawing comparison with the present-day love of pleasure and disregard of religious observance, following the Great War, and the widespread influenza epidemics. Whether these complaints were justified, it was not his duty to inquire, but to note the similarity of symptoms and their possible significance.

Industrialism and Health.

Miss M. C. BUER (Reading) contributed a paper on the effect of early industrialism of the eighteenth century on the health of the community. She drew attention to the decline in death-rates during the eighteenth century unaccompanied by change in birth-rate, as responsible for the rise in population between the years of 1750 and 1815, thus:—

	Death-rates per 1000.		Death-rates per 1000.
England and Wales	1750 .. 35 1815 .. 20	London	1750 .. 50 1815 .. 30

Economic advance had not been at the expense of the public health. The main part of the population in the eighteenth century were living in isolated communities where the death-rate was highest. In mediæval Europe, she referred to the influence of overcrowding, polluted water-supplies, lack of sanitation, and the failure of food-supplies leading to the killing off of cattle for conversion into salted foods. The shortage of green vegetables and root crops had given rise to marked prevalence of rickets and scurvy. Reference was made to the conditions in this country from records of the seventeenth century, when the towns were hot-beds of infection, and the water-supplies were polluted by the carcasses of dead animals in the conduits.

From the fifteenth century onwards there occurred the transition from an agricultural to an industrial state, and the growth of towns reacted on the extent of agriculture. The increase of vegetable culture led to a decrease of rickets and scurvy, and drainage, undertaken for cultivation, resulted in a decline in the prevalence of malaria. In the middle of the eighteenth century came the rapid growth of hospitals, and the end of the century was marked by important changes in the hygienic conditions of the army, thanks to the work of Pringle, Lidden, and Percival in their campaign against typhus, whose efforts ranked with those of Chadwick in the nineteenth century. In 1783, through the efforts of Haygarth, Leicester was first provided with a fever isolation hospital, and in 1797 similarly in Manchester a "house of recovery" was erected. At that time the campaign of cleansing dwellings with whitewash, the introduction of cotton clothing, and the substitution of iron for wood bedsteads had a combined effect on the prevalence of typhus, mainly the result of the work of Howard. Before the improvements begun in the middle of the eighteenth century, 75 per cent. of the children died before reaching the age of 5 years, but in the latter half of the century the heavy death-rate decreased following improvement in food and the rise in interest in child welfare. Lying-in hospitals were established, and the spread of knowledge showed itself in 1815 in the opening of the first baby clinic in London with instruction to mothers in infant feeding.

The change brought about in the second half of the eighteenth century was shown by the following figures from the British Lying-in Hospital—

	Maternal mortality.	Infant mortality per 1000 deliveries.
For the ten years ending 1758	24	66
" " " 1798	3·5	13

and at the Westminster Infirmary in the 30 years between 1750 and 1780, a decline in maternal mortality from 15 to 3·7 per 1000 deliveries was recorded. At the end of the eighteenth century, the death-rate, which exceeded the birth-rate up to 1820, when the reverse first showed itself, amounted to 22 per 1000 in the country districts and 30 per 1000 in the towns, and reached a higher figure earlier in the century. The earliest days of industrial evolution at the beginning of the nineteenth century, for the knowledge then existing, showed relatively greater improvement and lower mortality in comparison with the present day with its much more advanced state of education and scientific progress. As regards the correlation between economic conditions and hygiene, Miss Buer debated whether the slow rate of progress in preventive medicine and backward state of agriculture and industry in the east were merely an accidental association, or more likely, factors which were closely interdependent.

She concluded by stating her firm conviction that present-day civilisation in this country was far from effete, but intensely vital.

In the discussion following the three opening papers Prof. VAN LEERSUM (Amsterdam) referred to the uneasiness felt in Holland as to the frequency of thyroid enlargement, whether affected by the presence of traces only of iodine in the water-supplies. The fact that in the fifteenth and sixteenth centuries goitre was very common, to judge from frequent appearance in models of the period, showed that even with the improved conditions of water-supply its occurrence at the present day remained unaccounted for.

Dr. J. R. RATCLIFFE (Birmingham) was of opinion that, to obtain reliable evidence of changes in type of disease, systematic records of clinical symptoms were essential. He sought explanation of the changes shown by scarlet fever, once so serious, now merely a nuisance from the diagnostic point of view, and as to why chlorosis and anæmia had now practically disappeared, and membranous croup was no longer seen. Bacterial evolution was a question of the number of generations which succeeded each other so rapidly that a change could take place very much quicker than in the human organism, hence the possibility of change in type of disease in a relatively short space of time.

Lieut.-Col. STEPHENSON (I.M.S., retd.) dwelt on the medical interest attaching to the scientific writings of a Persian poet and historian of the thirteenth century, in a compendium of the various known minerals, plants, and animals, and the medicinal uses of each. The state of knowledge in the fourteenth century in Persia as regards disease, for instance, the accounts of what was probably diphtheria, of

quartan fever, and the distinction of gout from chronic rheumatism, argue that the east had possibly anticipated the west. That hemiplegia once fairly common in the Punjab was now rare, pointed to a decrease in arterial disease. The mention made of cataract, corneal opacity, stone, leprosy, tuberculosis, and ringworm, and their treatment, all of which were still common complaints, showed the development of medical science in a broad sense which had existed in mediæval Persia.

Dr. A. A. WARDEN (Cannes) alluded to the date of the first authentic case, confirmed by post mortem, of appendicitis in the death of Gambetta in 1881, maintained by Prof. Lannelongue to be due to appendicular abscess, for which operation was declined.

Dr. W. WRIGHT compared the conceptions of disease now known to be bacterial in origin, but attributed by the ancients to "semina," morbid influences, and "mal odeurs." All sensations were formerly ascribed to particulate matter, and the prevention of disease was confined to counteracting unpleasant effluvia by means of aromatic substances. The carrying of infection found mention in Shakespeare (Henry IV.) in reference to the filthy rags of continental immigrants bringing the semina of disease. Dr. Wright described the work of the late Dr. Charles Creighton on the history of medicine and epidemiology as a classic ranking with Gibbon's History of Rome. Appendicitis had been described by Sydenham in the reign of Charles II. under the name of the "iliac passion," the treatment advocated being the application of the warm belly of a living puppy. The earliest authentic case had been recorded by Heister, a famous Dutch surgeon in the middle of the eighteenth century, who in the course of dissection of the body of a criminal, found the appendix "beautifully injected, and lying free in the peritoneal cavity," and, moreover, stated that the appropriate treatment would have been the application of warm clysters. But for the first anatomical description of the appendix it was necessary to go back to the writings of the anatomist (Berengarius) in the sixteenth century.

Sir HUMPHRY ROLLESTON, in his reply to the discussion, mentioned accounts of appendicitis in the early years of the eighteenth century. Parkinson, who practised in Hoxton, had described cases, as also had Hodgkin, Addison, and Bright, among others. In explanation of the decline of chlorosis, alterations in dress and a more liberal diet in meat, made more easily available by transmission from America, had been put forward as contributing factors.

Prof. A. J. CLARK (Edinburgh) read a paper on

The Historical Aspect of Quackery.

He defined the quack as one pretending knowledge or skill which he did not possess, who preyed upon the unlimited gullibility of the general public, and was actuated by purely selfish motives of personal gain through the exploitation of human suffering. In Prussia, quacks were required by law to register, but in this country there was no such check on their activities, which had been in no way diminished by the spread of education and medical discoveries of the present day. It was remarkable that the greater the advances made by the medical profession, the more unpopular they became with the masses. The last century had seen much agitation against the successes of medical science—notably antivaccination and antivivisection—movements in which there was evidence of strong feeling of distrust of the profession and a readiness to turn to the charlatan who claimed to possess supernatural powers of healing. The common type of quack was a man of forceful personality who exhibited a profound belief in his semi-miraculous powers of healing, regarded himself as inspired and so independent of the too slow advance of science. Among the many quacks there had been in the past and at the present day he mentioned Perkins, who 100 years ago attracted an immense number of followers to believe in his power to cure all disease by stroking the body with two metal rods or tractors. The most recent quack appliances were forms of simple electrical apparatus, for which great claims as panaceas were made, and certain of them had succeeded in achieving remarkable notoriety, mainly in America—e.g., in the case of "Dr." Rogers for whose radio swindle the sum of 500 dollars was charged; also Gaylord Wiltshire, who about a year ago in California traded on his extraordinary facial resemblance to Bernard Shaw. He supplied an apparatus consisting of a coil of insulated wire, with plug and socket in the form of a horse collar which was claimed to magnetise the iron in the hæmoglobin of the patient's circulating blood and so to effect cure. Dr. Abram's box or reflexophone, for which preposterous powers of diagnosis and cure had been claimed, was an apparatus of quite simple electrical device; it had attracted, until his death, a remarkable following in America, and had met with considerable attention in this country, where professional inquiry had failed to justify the extravagant claims made for it.

Prof. Clark concluded by stating that the basis of the success of the quack was the innate belief of mankind in the supernatural, much the same now even, as among primitive races convinced of the reality of magic and largely under the influence of mass suggestion. Religion, in the form of Christian science, appealed to a large number of the more intelligent people at the present day, as a means of finding cure from a great variety of conditions of disease and akin to it was the faith in the virtue of a charm or incantation of which there were many familiar instances in common practice, all of which were evidence of the underlying belief in the power of magic and survivals of the large part played by the supernatural in the life of primitive man, and seen to-day so forcibly in the fetish worship of native races.

Reports and Analytical Records.

MONARCHISTA OLD PORT.

(J. G. THOMSON AND CO., LTD., THE VAULTS, 87, GILES-STREET, LEITH.)

THIS wine, which was matured in wood, when analysed was found to have the composition:—

Alcohol by volume	19·4 per cent.
Alcohol by weight (grammes per 100 c.cm.)	15·3 ,, ,,
Total sugar	11·32 ,, ,,
Sugar-free extractives—	
Fixed acid as tartaric	0·33 ,, ,,
Volatile acid as acetic	0·02 ,, ,,
Mineral matter	0·22 ,, ,,
Water	72·81 ,, ,,

Preservatives were tested for with negative results. The wine is light in colour with a good aroma and palate. It may be regarded as a well-matured sound port.

BALKAN SOBRANIE CIGARETTES (LARGE SIZE).

(ALBERT WEINBERG, 3, CARLISLE-STREET, SOHO-SQUARE, LONDON, W.)

The tin contained 25 cigarettes, each weighing 1·57 grm. (24¼ gr.); approximately 18 cigarettes weigh 1 oz. The paper of each cigarette weighed 0·0503 grm. (0·77 gr.).

On analysis the following results were obtained:—

Moisture	12·56 per cent.
Ash	16·26 ,,
Sand	0·70 ,,
Nicotine	1·10 ,,

The cigarettes are stated to be made of finest Yenidje tobacco, and the analytical figures support this statement. The tobacco is of a good quality, quite free from stalk and midrib, contains very little sand, and possesses an agreeable odour. The cigarettes burn slowly and evenly, and are cool to the palate and throat.

Reviews and Notices of Books.

TEXT-BOOK OF PSYCHIATRY.

By D. K. HENDERSON, M.D. Edin., F.R.F.P.S. Glasg., Physician-Superintendent, Glasgow Royal Mental Hospital; Lecturer in Psychological Medicine, University of Glasgow; and R. D. GILLESPIE, M.D. Glasg., D.P.M. Lond., Physician for Psychological Medicine, Guy's Hospital, London. London: Humphrey Milford, Oxford University Press. 1927. Pp. 520. 18s.

Dr. Henderson and Dr. Gillespie have produced a text-book of psychiatry well in accordance with the modern developments of psychological medicine. Their outlook throughout has been definite and consistent, being founded chiefly upon the teachings of Eugen Bleuler and Adolf Meyer. Again and again emphasis is laid on the important fact that the psychotic picture is largely determined by the character traits present in the individual in his normal healthy state, and that the mental picture may vary just as one individual does from another. Like Clouston they consider it "unphilosophic to say that mind cannot rank as a causative factor, it seems contrary to plain clinical fact . . . to set aside the mental treatment of insanity would be to deprive ourselves of our chief therapeutic resource in many cases."

Starting from these premises, the authors have written a useful book, and have shown a comprehensive grasp of modern methods of care and treatment. Although emphasis is primarily laid upon the psychic side of the problem, physical methods are given their place in the scheme of treatment; appropriate drugs, hydrotherapy, rest, open air, occupational therapy are all included. These are not extensively detailed; for instance, malarial treatment for general paralysis is dismissed with a brief survey, and the differentiation of appropriate cases is not even attempted. The Glasgow Royal Mental Hospital has considerably developed occupational therapy, and good results are claimed from it in a number of cases, a sine quâ non being intelligent coöperation between the instructors and the nursing staff. The authors believe auto-intoxication to be overrated as a causal factor in mental disease, and draw attention to the work of N. Kopeloff and George Kirby in this connexion. They suggest a classification of mental states which is in accordance with Bleuler's views of the various "types of reaction." The chapters on the psychoses are very clear; the authors prefer to speak of schizophrenia rather than of dementia præcox as a separate entity. Involutional melancholia is excellently dealt with and carefully differentiated from the depressive phase of manic-depressive insanity. The high standard of the sections on the psychoses is hardly maintained in the chapters devoted to the psychoneuroses. These seem to have been modelled largely on the work of J. Dejerine, and an attempt has been made to fill gaps by a reference to the conditioned reflex, which is in no way explained or elaborated. Psycho-analytic methods are given a place. The writers seem to base their comments mainly on the earlier works of Freud, for their description of the technique is scanty, and no reference at all is made to the mechanism of cure. They deny the necessity of a sexual trauma in the generation of a psychoneurosis; yet in many of the cases quoted in support of this contention there are obvious irregularities in the patients' sexual lives. The book closes with the usual chapter on the medico-legal aspects of insanity. The fact that carefully selected case-histories are frequently used to illustrate the various mental conditions, in conjunction with the clear and concise style, makes the book easy to read in spite of the excessive use of brackets.

Students and practitioners who desire a good insight into the theory and practice of modern psychiatry will be well advised to study this work.

THE PSYCHOLOGY OF CHILDHOOD.

By MARY SCHARLIEB, D.B.E., M.D., M.S. Lond., J.P. London: Constable and Co., Ltd. 1927. Pp. 194. 6s.

BOOKS on child psychology are extremely plentiful to-day, and are superficially much alike, but of very varying merit. Possibly none of them do much harm, as a mediocre writer will generally rely on the unexceptionable statements of a standard text-book, but no parent wants to waste time reading second-hand advice. The distinguishing feature of a book of this sort is the atmosphere which the writer manages to create in it, and which will incline the reader towards an attitude of mind more than instruct him or her in certain facts. Dame Mary Scharlieb has the highest qualifications of knowledge for this task, as she has brought up a family of her own, has carried on child practice for the large part of her life, and is a magistrate in a London juvenile court. The advice she gives is absolutely sound, and permeated with a refreshing comprehension of what is best in the modern schools of psychological thought. What perhaps, however, will capture a parent's confidence more than this is the atmosphere the book carries of ripe conservatism. There is no raw controversy nor tacit scorning of old beliefs. Dame Mary Scharlieb reminds parents throughout that the whole success of their venture depends upon their whole-hearted practice of the ancient virtues of mutual devotion and responsibility, and frankly advocates the practice by them of the traditional religion of the Church, and that they should instruct their children in it. Whatever a reader's individual views, he will not fail to profit by the ideal (that the writer holds up) of whole-hearted self-application to the most difficult task of all.

A DOCTOR'S VIEW OF LIFE.

By WILLIAM J. ROBINSON, M.D. Edited, with a biographical introduction, by EDEN and CEDAR PAUL. London: George Allen and Unwin, Ltd. 1927. Pp. 526.

THIS book consists of a miscellaneous collection of short articles, aphorisms, and jottings from the pen of an American medical man of wide literary and humanitarian interests. For nearly 25 years Dr. Robinson has been the editor of a paper, *The Critic and Guide*, from which the contents of this book are, for the most part, reproduced. They range over a wide variety of subjects—the Great War, travel, literature, character types, athleticism in America, and numerous contemporary medico-social questions such as birth control (of which the author has always been an insistent though temperate advocate), vivisection, dietetics, sexology, psycho-analysis, and others. These subjects are treated with a vigour, a candour, and a consistency of outlook which springs from a clearly formulated philosophy. It is the outlook of an advanced liberal, a pacifist, an advocate of freedom of speech and thought, an agnostic. Yet Dr. Robinson is no extremist. Though an agnostic he is tolerant, appreciative even, of the religious attitude; though a pacifist he is not an unresister; though desiring greater freedom of discussion and action in sexual matters, he is neither an advocate of unrestraint nor a believer in the pan-sexualism which now dominates psycho-analytic theory; though a birth-controller, he holds that births must be intelligently regulated in the light of racial and international as well as of personal issues. The position which he assumes is, therefore, one which exposes him to attack on both flanks—from opponents of his mode of thought and from extremists in the causes which he has espoused.

Dr. Robinson's fearlessness and candour—both of which, the reader feels, are rendered the more effective by his essential disinterestedness—have made him many enemies, especially during the war. But they have also made for him may sincere admirers and supporters.

THE LANCET.

LONDON: SATURDAY, OCTOBER 1, 1927.

THE NEW MEDICAL SESSION.

ON the first of October words of welcome may well be addressed to the students who to-day are beginning their studies in the various medical schools. The official introductory lecture is not now, as it was by former generations, considered to be an essential feature of the opening of the winter session; but in a few schools the old custom is maintained, while the speakers at various inaugural dinners, though addressing gatherings comprised mostly of qualified men, will be sure to reflect upon the course which medical training now takes, and to consider the professional outlook in its general and special developments. We believe that they will be able to congratulate with real sincerity those who have decided to enter upon the career of medicine, and also that those to whom the management of our professional education is entrusted to-day are aware of the great difficulties which attend the medical career, and are prepared to smoothe them for their juniors. No time will be wasted which is spent, as opportunity offers, in assisting the recent recruits to grasp the principles on which medical practice will have to be conducted, in whatever of the varying careers they may decide to adopt. Life in a medical school is well calculated to produce sympathetic recipients of such advice, for as a means for the development of character it is doubtful if any better training could be devised than the routine of the medical student both in the intensive nature of the studies and in the breadth of their purpose.

But the probationary training must often be truly bewildering to a recruit. The curriculum grows yearly more elaborate, and its rigidity is imposed upon it by an examination system for which nothing else can be substituted. So that the teacher and the taught are alike engaged in a fight against time. Yet it is essential that the medical student should have placed before him the fact that the object of his long years of study is not to pass examinations, but to fit himself to carry on a great corporate work for the benefit of mankind. It has long been advocated in these columns that opportunities should be made at medical schools for the giving of advice to those about to be qualified upon the conduct of medical practice. This implies no regret at the dispensing with the old apprenticeship system, for even when it flourished only a small proportion of the medical students had a sound conception of what may be called professional ideals, and there is no reason to suppose that the proper spirit cannot be thoroughly well inculcated in the medical schools of to-day. It is generally recognised that the ethical conduct of a doctor is dictated by the same rules and observances of neighbourly duty as the conduct of those who follow any other profession, and elaborate codes would not help the good doctor who is a good citizen, and might even defeat their object. No profession can be inspired with lofty endeavour by by-laws. Ethical rules to have value will be those which teach the student while he is still at the hospital, as the practitioner when faced with facts, that medical practice must be conducted in accordance with the spirit that makes all members of the profession ready to participate in the strengthening of authority for the prevention of backsliding, and equally ready where necessary to represent to authority that the guidance may itself need guiding.

The number of medical students registered during the year in each of the three divisions of the United Kingdom for the past 20 years appears now to stand in normal relation to the population, and the figures relating to qualification during those years have the same message. An increase of students from 1915 to 1920 arose distinctly out of the immediate needs of the war, and was reflected five or six years later in the larger number of those acquiring medical degrees or diplomas. Five years ago Sir DONALD MACALISTER, in giving to the General Medical Council the figures relating to medical students for recent years, pointed out that the number registered in 1920 was higher than any that had occurred previously save in 1919, the tendency having been steadily upwards since 1913. The figures to which he referred ranged from 1480 students in 1913 to 3420 students in 1919, and those who could read meaning into the figures felt safe in prophesying that a movement downwards in the entry to the profession would take place. This duly occurred, and the number of medical students in 1926 was actually a little below the figure of 20 years previously, and a little more than a third of the number in 1919. But the figure for 1926 is more than double the figure reached in 1923, when for no very obvious cause the alterations in the curriculum of study led to the registration of only 545 new entrants. The figures certainly suggest stabilisation, and do not support in any way the oft-repeated statement that the profession is or is likely to be overcrowded. It will be safe for those in charge of our new adherents to tell them that there is no risk of unemployment.

NEW LIGHT ON PERNICIOUS ANÆMIA.

EVERY contribution to our knowledge of pernicious anæmia deserves close attention, because it is a malady with a necessarily fatal upshot, and one which, according to a wide body of medical opinion, is becoming commoner every year. Interest centres at the moment around the claims of American workers to have obtained striking results from dietetic measures, and especially from the administration of diets containing large quantities of liver. Dr. G. R. MINOT and Dr. W. P. MURPHY, of Boston, have now published [1] a study of 105 cases of pernicious anæmia treated by this method during the last few years. In their previous communication, 18 months ago, they referred to 45 cases only, but many others have since come under their notice with results not appreciably different from those observed in the smaller series. Their successes have been confirmed by other American physicians, and unpublished reports from observers in this country have been of a like enthusiastic nature. In general the observed effect has been to restore the red corpuscle count from the low figure seen during the acute attack to something over 4½ million per cubic millimetre. Relapses have been singularly few, and cases which have done less well have almost uniformly been those in which insufficient amounts of liver were being taken. The diet prescribed by MINOT and MURPHY consists of about 200 g. of cooked liver per diem, with generous amounts of fruits and vegetables containing 5 to 10 per cent. of carbohydrate, together with red muscle meat. The total

[1] Jour. Amer. Med. Assoc., 1927, lxxxix., 759.

fat in the diet is low, not exceeding 70 g. a day. Sugar is diminished and concentrated carbohydrate and milk are not included to the exclusion of other foods. The cooked liver may be served in any way that pleases the patient, provided that excessive boiling is avoided. It is suggested that mammalian liver is preferable to that of birds, whilst kidney can occasionally be given as a substitute. A good many patients have preferred to take the liver in the form of raw pulp, and it is suggested that it has its maximum value in this form. 180 g. of such pulp divided into two portions and taken mixed with orange-juice has been found a useful prescription in some cases, whilst in others—especially those in which the patients were very ill and subject to nausea—it was found desirable to administer it through a stomach-tube. It is considered advisable to continue this treatment long after the blood-count has become normal, although a good many cases have remained well in spite of reducing the dose to 150 g. three times weekly.

The assessment of therapeutic benefit in pernicious anæmia must be regarded as exceedingly difficult because, whether treated or left alone, the patients have a tendency to improve markedly from their worst period, although they almost invariably suffer successive relapses, which finally lead to a fatal termination. Caution is therefore necessary in ascribing improvement to any remedy which has been administered. Published and unpublished accounts of the MINOT-MURPHY treatment suggest that with it improvement is more rapid and relapse postponed longer than with any other form of treatment observed during recent years. It is clearly impossible, as its authors themselves emphasise, to say whether this treatment is of permanent value until five or more years have passed; there can, however, be little doubt that the method is one worthy of widespread adoption in order that a valid conclusion may be drawn without unnecessary delay. So much for the observations themselves. The reasons put forward by Dr. MINOT and Dr. MURPHY for the success of their treatment are:—

1. The recognition of the similarity of many symptoms and signs of pernicious anæmia to those of pellagra, sprue, and beri-beri.

2. The observation "that patients with pernicious anæmia have often taken an abnormal diet for many years, noticeably one with a deficiency of red meats and an excess of fats particularly derived from dairy products and pork."

3. The geographical distribution of the disease.

4. The knowledge that secondary anæmia is frequently associated with a faulty diet.

5. The fact that patients with pernicious anæmia often had better health "when placed on a well-balanced and high caloric diet containing excess of nitrogen."

We doubt whether these reasons will make any great appeal to those with wide experience of the disease. In the same journal will be found an account [2] by Dr. K. K. KOESSLER and Dr. S. MAURER, of the University of Chicago, of the results of treating pernicious anæmia with a diet of high caloric value and rich in vitamins. Their report covers 40 patients who have been treated during periods ranging from six months to two years. No definite statistics are given concerning the total results save that all the patients, with one exception, are alive and in good health with a normal blood picture. Liver in liquid extract form is part of the diet in many cases, and these authors also lay stress on the faulty diet which is presumed to have preceded the onset of the disease. In contrast to the Boston school, the Chicago observers state that a low fat-content is not justified and large amounts of cream, butter, milk, and cod-liver oil are advised. The efficacy of liver and kidney is considered due to the high content of vitamins A and B in these organs. It is clear that we are here faced with a dietetic régime largely empirical, in which the presence of a considerable quantity of liver is the one outstanding feature.

A further difficulty in assessing the effect of treatment in these cases is the fundamental difficulty of diagnosis. It is true that in this country pernicious anæmia stands almost alone as the cause of really severe anæmia with disproportionate fall in the total number of red corpuscles. But—with the possible exception of the Price-Jones curve—we have no infallible test enabling us to say without doubt that this or that case is one of pernicious anæmia. As soon as successful treatment prevents relapse and autopsies become the exception, it is going to become almost impossible to decide whether the cases dealt with have really been examples of the malady described by ADDISON. A paper [3] by Dr. D. I. MACHT, of the Johns Hopkins School of Medicine, Baltimore, which also appears in the same journal, promises to be of value in this respect. He has tested the blood serum in many cases of this and other blood diseases, and believes that in pernicious anæmia the serum shows a toxic effect upon plant protoplasm quite different from that observed in the control cases. Briefly the method consists in placing seeds of *Lupinus albus* in blood serum, and measuring the inhibitory effect on growth exercised by the blood serum from pernicious anæmia cases. It is believed that the somewhat complicated procedure affords a genuine diagnostic test. Exposure of the serum to irradiation with ultra-violet rays is claimed to have the effect of making it less toxic, and the intravenous injection of substances such as eosin with subsequent ultra-violet irradiation is claimed to have given promising therapeutic results. The complexity of this latest inquiry is such as to invite a special caution, but in so far as it affords a possible new channel for diagnostic exactitude it will command attention.

[2] Jour. Amer. Med. Assoc., 1927, lxxxix., 768.

[3] Ibid., p. 753

SIR ARTHUR SHIPLEY.

THE late Master of Christ's College, Cambridge, was a well-known figure in College and University circles, and this he deserved in respect of his qualities as a just administrator and able organiser. He was known throughout the scientific world as a zoologist, and this in response to a mass of work partly of research and partly of literary character and all bearing the impress of unflagging industry. But beyond this SHIPLEY had impressed the world at large by the breadth of his sympathies, the keenness displayed in the wide range of his interests, and his gift for recording his impressions in a clear and attractive style. He began his career with the intention of becoming a doctor, but the Cambridge school of zoology, with MICHAEL FOSTER and his great pupil, FRANCIS BALFOUR as teachers, attracted him, and he never pursued the whole medical course, turning aside to the fascinating study of zoology. But for many years at Cambridge after his own promising undergraduate period was over, his zoological work brought him into contact with the medical school, so that many practitioners will remember SHIPLEY as an enlightening lecturer and a suggestive

writer and many more as indirectly an examiner. For SHIPLEY examined for the Natural Science Tripos for many years, during which it was usual for the medical candidate to take as his subjects those which he would require later for professional tests, while his text-book on the Zoology of the Invertebrata was in use for an extended period among undergraduates, during which time he was demonstrator of comparative anatomy in the University and lecturer on advanced morphology. SHIPLEY'S later work, neither the original researches which brought him the F.R.S. nor the joint editorship of the Cambridge Natural History, had any close relation to medicine, but such connexion as there was he availed himself of by contributions to Allbutt and Rolleston's "System," and by two useful and amusing books of parasitology entitled "Minor Horrors of the War." Probably few men of SHIPLEY'S age, not actually professional soldiers, appreciated better than he did the life of the man in the trenches, for he placed Christ's Lodge at the disposal of the medical authorities in 1915, and his study, in which he still contrived to work, became the sitting-room of a convalescent home always crowded with injured men. SHIPLEY'S pictures of the parasitology of the war were drawn from the life, and contained many medical lessons. In short, though not a doctor, he was one to whom our profession owed a real debt.

Annotations.

"Ne quid nimis."

THE PROLONGATION OF HUMAN LIFE.

TEN years ago a new precedent was created in the publication of the Registrar-General's decennial supplement, the preparation of its life-table portion being entrusted to Mr. George King, F.I.A., instead of being done by the staff of the General Register Office. That report was invaluable not only for the multiplicity of the local and national life-tables given in it, but also because it made it possible to compare life-table data for the periods 1901–10 and 1910–12 by means of exactly comparable data (because calculated on a uniform basis) for earlier periods in our national registration history. The present life-table report [1] has been prepared by Sir Alfred Watson, the Government actuary, who happily has adopted in the main Mr. King's technical methods, thus preserving that accurate comparability with earlier periods which it is extremely important to maintain. The present differs from previous life-table supplements in containing no life-tables giving the average experience of 1911–20. The reason for this at once appears. The Great War disturbed the natural course of life, and the events of the decennium as a whole would have little value as a measure of national vitality. Apart from this, the plan of taking the vital statistics of the three years, 1920–22, which centre around the census year, offers great practical facilities and gives us a measure of national vitality of greater current interest than one dealing with an already obsolescent experience.

Sir Alfred Watson has given himself a more limited scope than his predecessors as regards variety and number of life-tables; and we should also have welcomed a fuller commentary on the tables given from his competent pen. Subject to these slight regrets, the report is one which should be studied by all interested in the national health. In a subsequent special article we shall attempt to give some of the most important results of his work. As Sir Alfred Watson points out, the most useful tests of vitality are (*a*) the rate of mortality of different ages; (*b*) the number of survivors, at different ages, of a given number born; (*c*) the expectation of life at different ages; to which may be added (*d*) the probability of surviving, say, ten years at any given age. The death-rate in age-periods can be given without constructing a life-table, and nothing detracts from its supreme importance. The number of survivors beyond a given age out of a given number born, like the expectation of life at any given age, represents in a life-table the summarised experience of many ages; while the number of survivors at the end of any ten years of life out of a given number beginning those ten years, like the corresponding death-rate represents the vitality in that particular period.

The expectation of life, although in some respects not so useful a measure as the others named above, has been so long used, that it may be well to give in this article a few figures under this heading, leaving for later consideration the remainder of the report. If the English Life-Table No. 7 (experience of 1901–10) be compared with the English Life-Table No. 8 (1910–12) and with the English Life-Table No. 9 (1920–22) at four ages of life, the following result is seen:—

Expectation of Life.

Year.	Males. Age.				Females. Age.			
	0	20	40	60	0	20	40	60
1901–10 ..	48·5	43·0	27·0	13·5	52·4	45·8	29·4	15·0
1910–12 ..	51·5	44·2	27·7	13·8	55·4	47·1	30·3	15·5
1920–22 ..	55·6	45·8	29·2	14·4	59·6	48·7	31·9	16·2

On an average a male child born during 1920–22, on the basis of the experience of mortality in those years, may expect to live 7·1 years longer than a male child born in 1901–10, the difference for a female child being 7·2 years. Similarly, a young man, aged 20, in the more recent period can expect to live 2·8 years longer and a young woman 2·9 years longer than in the earlier period; and even when the age of 60 is reached a male born in the later period can expect on the basis of the experience of 1920–22 to live 0·9 year longer, and a woman born in the same period can expect to live 1·2 years longer than one born in 1910–20. The preceding statement illustrates the value of this function, the expectation of life, in summarising in one figure the entire experience of life subsequent to a given age, and for this reason its use will doubtless be continued. But it does not show clearly at which part of life the gain has been secured; and for this purpose either death-rates for age-periods or the probability of living, say, ten years, are required. To the use of these tests we propose to return.

THE CLEAN MILK PROBLEM.

MILK and green vegetables, says Sir George Newman,[1] are of the greatest importance in any practical attempts to arrive at a satisfactory diet; they are protective foods and make up for the deficiencies of articles such as bread, sugar, fat, pulses, and potatoes, which are relatively cheap and therefore form the staple nourishment of our population. Unfortunately, milk and green vegetables are not consumed as largely or as widely as they should be. Vegetables are dear—although they could be cultivated in abundance—because the means of distribution to our cities are so faulty. Milk also is expensive, and for this and other reasons its consumption is astonishingly small. The amount taken daily in England and Wales is estimated at about one-quarter of a pint per head of population, and it is obvious, in the light of recent experiments on growth and nutrition, that the national physique

[1] The Registrar-General's Decennial Supplement, Part I. Life-Tables. 2*s*.

[1] Annual Report of the Chief Medical Officer of the Ministry of Health for 1926, p. 185.

would benefit if it were considerably increased. One of the factors that would promote such an increase is confidence in the purity of milk and in its keeping qualities; in other words, a cleaner supply would bring about a greater demand. And although the medical profession could and should do much to popularise milk as a food, it has also a duty, as Prof. F. T. G. Hobday shows in an article on page 738, to encourage all attempts being made to ensure its purity. Milk ought to be clean, and would soon become so if the profession were to use its influence in this direction.

The greatest difficulty is to free the milk-supply from tubercle bacilli. Sir John McFadyean, speaking at Torquay the other day, said that there is hardly one of the 230,000 herds in the country which does not contain an infected animal, whilst Prof. Hobday quotes an estimate that the number of tuberculous cattle is nearly a million. From this it is obvious that the immediate remedy cannot be wholesale slaughter, but the magnitude of the problem need not provoke despair. By regular inspection of herds it is possible to detect nearly all the animals which are infective. Under the Milk and Dairies Order and the Tuberculosis Order county councils are expected to control the diseases of dairy cattle in their areas, and a certain number have started routine periodical inspection of these animals by veterinary surgeons. This is likely to have far better results than any half-measures, and an active policy is essential. The Tuberculosis Order certainly cannot be trusted to put things right by itself, for the effect of merely offering compensation to those who own infected cows is to allow ignorant or unscrupulous farmers to delay notification until their animals have reached the terminal stages of the disease. As Dr. William Savage has forcibly argued in our columns,[2] the Order permits them to claim compensation after allowing their cows to disseminate disease, both to human beings and bovine contacts, over a long period, whereas it ought rather to inflict a penalty for failure to notify disease as soon as it is suspected. The early symptoms and signs are admittedly equivocal and diagnosis at this stage is a matter for veterinary surgeons. The services of these experts, therefore, should be freely at the farmer's disposal, so that he has no reason or excuse for inaction. At present, even when a case of open infection has been found, there is little or no inducement to the owner to have the rest of his herd examined.

The removal of animals with obvious tuberculosis is both valuable and necessary, but it is even better to get milk from herds which have no infection at all. Steady progress is being made in the production of tubercle-free milk, and in 1926 there were 252 herds, comprising 9100 dairy cows, supplying pure milk of this kind, which is labelled either Certified or Grade A (tuberculin tested). We have previously discussed[3] the advantages and disadvantages to the farmer of keeping cattle which do not react to the tuberculin test, and now need only repeat the statement that the greatest disadvantage is the absence of a market for the milk which they produce. Prof. Hobday shows that at Reading, thanks to the admirable work of the National Institute for Research in Dairying, an adequate supply of milk from tuberculin-tested cows is retailed at prices only a little higher than the ordinary, and it is certain that a public demand, stimulated by the medical profession, would lower these prices still further. People who can afford pure milk ought to buy it. The attempt to secure real cleanliness, although made by comparatively few milk-producers, has already done much to raise the standard of production in dairies which have not themselves begun to supply graded milks. As "Dairy Farmer" says in his letter on page 740, the farmer is finding more and more that scientific methods are not only patriotic but profitable.

THE JEWISH HEALTH ORGANISATION OF GREAT BRITAIN.

A WORLD Union for Preserving the Health of the Jews, which bears the abbreviated title of "OZE," was founded in 1912 by a group of Jewish physicians in St. Petersburg and was reorganised ten years later in Berlin when branches were established throughout Europe. In Eastern Europe, where a succession of disasters has shattered the health of the Jewish community, the work of the Union has largely been in the nature of relief of distress and the treatment of epidemic disease, but in Great Britain, where conditions have been happier, the programme of the Organisation has taken on more of a preventive character. The aims and methods of the Organisation in this country may be briefly stated as (1) to raise the standard of the physical health of Jews in Great Britain; (2) to supervise the sanitary conditions of Jewish homes, schools, and workshops, by way of supplementing the work of local authorities; (3) to collect statistics concerning the expectation of life, anthropometry, and pathology of the Jewish community; (4) to publish and distribute literature on health topics; (5) to organise lectures on health and to arrange for a museum of hygiene. All these objects have already been to some extent achieved: the Saturday evening lectures held for four winters at the Whitechapel Art Gallery have been widely attended; the various Jewish burial societies have agreed to supply monthly returns of deaths, and over 50,000 death-records have already been collected and collated with a view to determining the prevalence of cancer; 2000 children attending Jewish evening schools have been examined for their type of visual defect; and a report is now ready and will be published shortly on the comparative intelligence of Jewish and non-Jewish school-children, 2000 of whom between the ages of 8 and 14 have been tested. The Council of the Organisation has also been investigating the curious prevalence of left-handedness among Jewish children as compared with non-Jewish. The latest effort of the Organisation is to open a clinic for nervous and defective children on a small experimental scale at the Jews' Free School where the milder disorders of personality and behaviour are to be investigated with a view to their constructive treatment. The heavy financial responsibilities so incurred are met entirely by voluntary contributions, and an appeal for support has been issued signed by prominent members of the Jewish community. The hon. treasurers of this appeal are Lord Rothschild and Sir Samuel Instone, to whom donations may be addressed at 4, Upper Gloucester-place, London, N.W. 1.

MEGALOCOLON IN INFANCY.

DILATATION of the colon in infancy may be due to definite narrowing of the intestine or anal canal or may occur without any sign of stricture. The latter condition, known as Hirschsprung's disease, has been attributed to spasm and muscular incoördination, but these terms are not very exact and the underlying mechanism is not fully understood. Dr. Joseph Brenneman has recently described[1] six cases of megalocolon in early infancy which he has observed during the last 16 years. The patients were first seen at ages between 2 weeks and 3 months; most of them vomited and all of them had obstinate constipation and distended abdomens. In five of them it was found that there was a firm constricting ring with a sharp edge 2–3 cm. from the sphincter ani. (In the sixth case the distance was not measured.) The obstruction offered definite resistance to the finger but yielded gradually to digital dilatation, and although at first it was often difficult to insert even the little finger the resistance was overcome by considerable slow pressure and in time the index-finger could be used. Treatment by this method for severa

[1] Jour. of Amer. Med. Assoc., August 27th p. 662.

weeks led to recovery in four of the cases; the distension disappeared, the bowels became regular, and three months later they were apparently cured. In one case the stricture was relieved, but the late result is not reported, whilst in one the baby died. The latter case is particularly interesting, because at autopsy there was no sign of stricture although a tight ring with a sharp edge had been felt during life. Dr. Brenneman considers that these six cases are an example of a congenital anomaly identical with more severe malformations in this region but very restricted in extent. As a result of failure of the descending mesenteron to fuse with the ascending proctodæum a membrane may be formed resembling a hymen and having a central aperture. The consistence of the obstructing membrane depends on the number of layers which form it. He comments on the fact that most of the recorded cases of stricture have been treated surgically, the patients often being people of considerable age, and whilst agreeing that for anal obstruction surgery is often the only hope, he suggests that many constrictions can safely be treated and cured by dilatation.

MENTAL DISORDER IN SCOTLAND.

COMPETITION is as valuable a spur to progress in medicine as in commerce, and it is of interest to compare the annual report of the General Board of Control for Scotland with that of the English Board, reviewed in our columns last week (THE LANCET, Sept. 24th, p. 677). The Scottish Commissioners do not enter into that full discussion of the situation which makes such interesting reading in the English report, and the volume is largely taken up with statistics and tables. Although the preamble deals mainly with the problem of the mentally defective, Scotland does not appear to be so much concerned with the difficulties of ascertainment and accommodation. The chief anxiety seems to be the state of public opinion, as stress is laid on the desirability of institutional training and the fact that certified defectives are periodically reconsidered with a view to release. The total number of defectives on the register is 2764. The English Board regards 1 per 1000 as a very conservative estimate of the defectives in our population, and as there are nearly 5 million people in Scotland, it is evident that either the proportion of defectives is very much lower than in England or else many have not yet been "ascertained." A large number are still unsuitably detained in institutions for the insane and the colony system is in its infancy. There is a colony at Waverley Park for 110 girls and excellent progress is reported in developing the patients' capacities. The colony is the result of voluntary effort, and to the splendid work of the Scottish Association of Women Citizens is due the purchase of 750 acres by the Royal Scottish Institution at Larbert for another industrial and farm colony for adolescents. There are 11 other certified institutions and 1000 patients are in private dwellings. The increase in defectives registered during 1926 was only 140. The Board is carefully watching the fate of sufferers from encephalitis lethargica, for whom there are ideal observation wards at the Stobhill General Hospital. The label, "post-encephalitic mental defect," is deprecated, on the ground that such patients may still have a chance of complete recovery if properly and actively treated.

At the beginning of the year there were 18,580 insane persons under official cognisance, including 68 criminal lunatics at Perth, and 45 imbeciles, not certified under the Mental Deficiency Act, in training schools. The ratio to the population corresponds with that of England. In poor-houses there were 1090 and in private dwellings 1718. The English Commissioners constantly plead for more extended use of those sections of their Act which permit the transference of harmless incurable patients from institutions which are or should strive to be mental hospitals, to private guardianship and Poor-law wards. In this respect Scotland, with nearly one-sixth of its insane population outside the asylums, is nearer the ideal than England. The report regrets the decrease that has occurred since the war in the number of boarded-out lunatics. This decrease is partly due to economic factors; higher agricultural wages made it more difficult to find guardians in the country and the increased cost of living made city Poor-law authorities unwilling to take patients at the low board-rate. With the return to normal conditions the Commissioners hope to get more patients boarded out; maintenance is cheaper outside than inside an asylum, and there can be no doubt that aged senile lunatics are far happier sharing a "home" atmosphere, however humble, than in the best of institutions. This provides no argument against certification, however, for the report notes that they are generally better cared for by strange guardians than by their relatives.

In sharp contrast to the year's increase of 2743 in England, Scotland actually showed a decrease of 90 in the number (2304) of persons certified for the first time during 1926. The number of voluntary patients admitted to mental hospitals during the year was 628, nearly double the average figure for the ten preceding years. The Crichton Royal Institution achieved, in the second six months, the distinction of admitting 17 more voluntary than certified patients. The death-rate for the year was 8·3, the recovery-rate 35·9. Both figures show improvement on those of 1925, and are comparable with the English figures. The Scottish death-rate remains a little high. The average standard of care and treatment in the mental hospitals is excellent, as we have noted in considering them individually under the heading of "Mental Hospital Reports." There are seven Royal asylums, 21 district, and two private asylums. One of the last is a new house for Roman Catholic ladies opened last year by the Order of Augustinian Sisters; it has at present five voluntary boarders. Fourteen poor-houses have lunatic wards. There were only four suicidal deaths during the year. In 1926, 98 patients were sent out on probation; of the 48 whose period expired during the year, 17 were finally discharged as recovered. Less use seems to be made of this important trial trip system than in England. Despite the gratifying advances in treatment year by year, the dominant note of the English report is one of anxiety and urgent need for further efforts. From this distress the Scottish report is free.

LEGAL AID FOR PRACTITIONERS.

THE annual general meeting of the Medical Defence Union was held on Saturday of last week at the Royal Bath Hospital, Harrogate. It is well that the Union should meet from time to time outside the metropolis, for it is in the more rural areas that the practitioner is most in need of legal help and least likely to obtain it, except at the hands of a central organisation. No doubt north country practitioners are as able as any to conduct their own affairs without assistance, and may even cherish a not unreasonable belief in the combination of rugged integrity and judicious self-interest, but the solicitors to the Union point out that practitioners unaided are at the mercy of a section of the public who seem to think they are justified in raising any claim, however extravagant and unwarranted, to avoid payment of their just debts. By these persons members of the medical profession are regarded as fair game whenever some slight error of judgment, some momentary distraction of attention plays into their hands. The Union is precluded by its constitution from simply undertaking debt collection, but, so soon as a charge of negligence, threatened as a possible defence to a claim for fees, has been definitely recorded, the experience of the Union is at the practitioner's service. Every point in his favour is brought to the forefront, and every step taken to defeat the claim if unjustified, or, if justified, to ensure that the claim is equitably adjusted.

The policy of the Medical Defence Union is definitely against any settlement out of court, for, in settling a claim which has no merit, the practitioner is really giving way to blackmail and encouraging similar claims against his professional brethren. In five of the cases in which a claim for damages was brought or threatened during the past year, the only negligence alleged was the failure to direct the patient to have an X ray examination made of the injury for which he was under treatment. The Union therefore begs the practitioner, if only for his own protection, to advise his patient in any such case to undergo an X ray examination, and, if this is refused, to ensure that there is some evidence of the advice thus given, either in the form of a witness, a letter written at the time, or a note in the case-book. Even the practitioner with a case so clear and good that he readily obtains a verdict against his patient with costs is not thereby protected against financial loss. During the year the Union only recovered against the other side the sum of £30 9*s*. 6*d*. out of the many hundreds of pounds to which it was entitled as the successful litigant. Indeed, the Finance Committee of the Union lays stress in its report on the fact that heavy legal costs are often incurred in the most successful cases, because, when the people who bring the action are possessed of no means, a verdict with costs affords no financial relief to the costs of the defence. This Committee invites attention to the cost incurred in defending six cases in 1926, amounting in all to £1821, while the amount paid in yearly subscriptions by these six members was only £77. It is impossible for the Union to insure itself against exceptionally heavy expenses from the payment of damages in any particular year; hence the value of a large reserve fund, and incidentally, the convenience of prompt payment of subscriptions.

The report also calls attention to the less spectacular portion of the Union's work—namely, the many times in which the solicitors sat as legal assessors to the General Secretary in arbitrations between members of the medical profession. Since its foundation the Union has aimed at promoting unity within the profession and discouraging intra-professional disputes. It has never advocated complete indemnity or protection for medical men, but merely that those who are doing their duty honestly and rendering their services to the best of their ability should have a reasonable measure of protection. The Union gives its members the assurance that no action can be brought against them without reasonable cause.

NURSES AND THEIR WORK.

A FORTNIGHT ago Dr. T. F. G. Mayer called attention in our columns[1] to the ill-effects that result from constant standing and asked why nurses should be kept perpetually on their feet when so often they might do their work better sitting. The two correspondents who replied to his letter last week[2] took different points of view. One of them, the matron of a large provincial hospital, thought that nurses must be getting rather tired of people taking up the cudgels on their behalf, and said that they were encouraged to sit at their work whenever possible. The other, also an authority on nursing, said that the matter called for serious attention; many nurses feared to sit lest their patients should think they were relaxing unnecessarily, and it would be a great help if in giving directions the medical man would indicate that certain treatment would be better carried out while sitting, thus reassuring the patient and training the nurse to conserve her strength. This seems to us an excellent suggestion. It is quite true that in past years there was much stiffness and unnecessary discomfort to be borne by nurses and there are doubtless survivals still. A few of those who suffered greatly from discipline are apt to insist on such rigid behaviour from their subordinates. It would be wrong, however, to suppose that in the training hospitals of to-day nurses are kept on their feet unnecessarily. If there is something to be done at which a nurse can possibly sit she will probably remain glued to a chair as long as she can, and this with the complete approval, and probably at the request, of the reigning sister. On the other hand, aching feet are ever present, especially among the recruits, and this is, of course, because they hardly ever have time to sit down. Whilst the health of the nurses is carefully considered in most hospitals, it is none the less true that the departure of one of them from a large ward where the work is heavy throws a big extra load on those left behind; for there is seldom the chance of a "relief" coming to take her place. Thus it is unusual to report any but the most incapacitating indisposition, though this state of things is naturally contrary to the expressed wishes of the authorities. Holidays have to be deferred and a given date can seldom be depended on, because in most hospitals, however large, there is not an extra staff sufficiently large to fill all gaps, including the unforeseen. Nothing can prevent nursing from being a hard life; from its very nature there is always something to be done and something which will not wait. But the present situation could be improved if there were more nurses. "Matron" shows this when she says that a nurse is practically certain of being able to obtain another post. In big London hospitals the shortage is largely due to lack of accommodation, for there is little money available for building. Nevertheless, things have altered much more since the war than is generally supposed, and in the best hospitals nurses now have good food and rooms, a fair amount of recreation, and—generally speaking—excellent care when they report sick. The need is for a greater number of enthusiastic girls to take up this form of work, which during the years to come should offer more and more of the ingredients of happiness.

EXAMINATION OF TUMOURS OF THE BREAST.

Prof. John Fraser, of Edinburgh, delivered to the American College of Surgeons in 1926 an address, recently printed,[1] containing some observations on carcinoma of the breast based on the examination of sections made on the key-block system. The breast is divided into two portions through the area which is to be examined. From the surface of one portion a celloidin "whole" section is cut, and this will give the general topography of the gland. From the corresponding surface of the other portion a series of numbered blocks of smaller size are cut in paraffin; these will give the finer histological details of every portion of the "whole" section. The main points which emerge from the examination of 50 mammary glands are the following: (1) Any classification of malignant breast tumours is unsatisfactory because it is found that often one "whole" section exhibits in different parts several different types. The varieties known as "scirrhous" and "encephaloid" may be found side by side, and these terms thus become, more than ever, of academic significance only. (2) Prof. Fraser has been greatly struck by the fact that the epithelium in the ducts and acini for some distance around the malignant growth shows a change in the direction of proliferation, apparently as the result of exposure to a fluid-borne or secretion stimulus. This may be derived from the malignant focus or may be responsible for both malignant and non-malignant changes, and the realisation of this affects for Prof. Fraser his whole conception of the pathology of malignant disease. This observation is, however, not quite new. Attention was drawn to it by Mr. Geoffrey Keynes in a Hunterian lecture delivered in 1923.[2] This observer approached the problem from another angle, studying first the changes seen in "chronic mastitis" and suggesting that a secretion stimulus was probably responsible

[1] Surgery, Gynecology and Obstetrics, 1927, xlv., 266.
[2] British Journal of Surgery, 1923, xi., 89.

for these. The distant epithelial changes surrounding a carcinoma seemed, then, to afford some confirmation of the first idea. It seems possible that much may yet be learned of this aspect of the pathology of malignant disease from the study of the effect of various chemical agents on the cells of living tissue cultures.

SOCIAL HYGIENE AND THE EMPIRE.

THE British Social Hygiene Council, which was formerly known as the National Council for Combating Venereal Diseases, has organised another imperial conference to be held at the Caxton Hall, Westminster, from Oct. 3rd to 7th. The proceedings will open on Monday morning with a welcome to delegates and addresses by High Commissioners for the Dominions and representatives of Government departments. The principal subjects to be considered are Social Hygiene in India and the Crown Colonies, Protectorates, and Mandated Territories, Seamen's Welfare in Ports, and Social Hygiene in its Medical, Educational, and Administrative Aspects. As is natural, a large number of medical men will take part in the discussions. Surgeon-Captain T. B. Shaw will give an account of the Incidence and Prevention of Venereal Disease in the Navy, Sir George Buchanan will speak on the Development of Welfare Work among Seamen, and Major R. B. Lloyd, I.M.S., will read a paper on the Wassermann Test in India. The section of the congress dealing with the medical aspects of social hygiene will meet under the presidency of Mr. David Lees, Mr. Kenneth Walker being the secretary. Colonel L. W. Harrison will speak on the Modern Treatment of Syphilis and its Results, and Prof. F. J. Browne on the management of venereal disease at antenatal clinics. In other sections Dr. A. M. Fleming will describe venereal disease among the natives of Southern Rhodesia, and Dr. K. S. Wise will read a paper on methods of propaganda in Trinidad. Dr. Crichton Miller is to deal with the scientific foundations of character training, whilst on the last day of the congress, on Friday, there will be a discussion on the powers and responsibilities of local authorities in the venereal disease campaign, in which Dr. J. R. Kaye, Dr. A. S. M. Macgregor, and Dr. R. M. F. Picken will take part. After a paper on venereal disease in New Zealand, by Dr. Bernard Myers, the congress will close with a discussion on the problem of congenital syphilis in children of school age. Among the special arrangements made for participants will be visits to treatment centres, and the exhibition of films. The amenities will include a congress dinner, at which the Minister of Health will be present. Fuller particulars may be had from the Secretary-General at Carteret House, Carteret-street, Westminster.

INDICATIONS FOR CIRCUMCISION.

IN our last issue Mr. A. J. C. Hamilton and Mr. D. S. Middleton put on record their observations on infants recommended for circumcision during a period of a year at the Royal Edinburgh Hospital for Sick Children. Over half of these patients were found to be suffering from dysuria due, they concluded, in a majority of cases, to ammoniacal dermatitis. They showed how under certain circumstances urine normal when passed becomes infected from the alimentary canal by a bacillus which liberates ammonia from the urea in the urine-soaked napkin. Thus a kind of ammonia fomentation is applied to the bathing-drawers area of the child and dermatitis results. This condition was found to be amenable to the very mild antiseptic action of boric acid when the napkins were impregnated with it; 103 cases of dysuria were treated by this method with "almost uniformly good results," and the number of circumcisions was reduced to half the usual total. Lack of cleanliness is admittedly the first cause of these eruptions, and the mothers of all patients suffering from them were instructed to change their babies' napkins "frequently." A series of control cases would be necessary to determine whether the boric acid is an essential part of the treatment; in the meanwhile, the boric treatment is commendable for its safety and easy application. It appears that the dermatitis which the authors describe is commoner in Scotland than in England, where dysuria in babies, as seen at out-patient departments, is commonly associated with congenital stenosis of the urinary meatus. True phimosis with sufficient stenosis to cause mechanical obstruction to micturition is very rare—there will be general agreement with the authors in this statement—but with true "pin-hole meatus" the case is otherwise. Diagnosis of this condition may be impossible before circumcision, and it is well to remember that dysuria is the commonest of the many symptoms due to stenosis. Regarding circumcision and its substitutes, it is clear that circumcision is no remedy for "ammoniacal storms," but neither is it a remedy for many of the conditions for which it is so lightly performed. It may, in fact, be admitted that the operation is often done unnecessarily. But because the foreskin protects the glans penis from such an outrage against nature as an ammonia fomentation, it does not follow that circumcision stands condemned. The authors' substitute for circumcision when there are adhesions between the glans and the prepuce is probably well known to many careful mothers and nurses and has a definite place in nursery hygiene. None the less, we are sufficiently old-fashioned to think that a small boy should give the very minimum of attention to his external genitalia. That minimum is necessary for cleanliness, but both cleanliness and "unawareness" are, in our view, attained in many children most quickly and most permanently by the ancient operation of circumcision. There are two principal anatomical reasons for advising circumcision in babies—viz., a tight foreskin and a long foreskin. These indications, however indefinite and unscientific, are found to be useful guides in actual practice.

Summer Time, which commenced on April 10th, will cease on Sunday next, Oct. 2nd, at 3 A.M., when the clock will be put back to 2 A.M. The hour 2–3 A.M. Summer Time will thus be followed by the hour 2–3 A.M. Greenwich time. In France the change occurs eight days later.

AT the Royal College of Physicians of London the Bradshaw Lecture, entitled "The Pathology of Pneumonia," will be delivered by Dr. J. F. Gaskell on Nov. 3rd. Dr. Herbert Spencer will give FitzPatrick Lectures on Nov. 8th and 10th, taking as his subject "The History of British Midwifery." Dr. P. C. Varrier-Jones has chosen for his Mitchell Lecture on Nov. 15th "Village Settlements for the Tuberculous." The Lloyd-Roberts Lecture will be delivered at the Medical Society of London by Lord Hewart on Nov. 16th, his subject being "Criminal Law and Insanity." To all of these lectures any member of the medical profession will be admitted on presentation of card. The time of the lecture in each case is 5 P.M.

UNIVERSITY OF LONDON: *University College.*—A course of six lectures on Vision will be given at the College by Mr. R. J. Lythgoe, at 5 P.M., on Mondays and Wednesdays, from Oct. 10th to 26th inclusive. Mrs. P. M. T. Kerridge will give a course of three lectures of Hydrogen-ion Concentration at the College, at 5 P.M. on Fridays, Oct. 14th, 21st, and 28th. A lecture entitled "The Static Reflexes of Magnus: How Animals get right-way-up and keep so," will be given by Prof. A. J. Hall, F.R.C.P., on Tuesday, Oct. 18th, at 5 P.M. (cinematograph illustrations). Admission to these lectures is free without ticket.

DONATIONS AND BEQUESTS.—Mr. Herbert Augustus Hance, late of the King's Remembrancer's Department, Royal Courts of Justice, among other bequests, left £2000 to the Royal Victoria Hospital, Folkestone, to endow two beds. Certain residues of the property also go to the Royal Victoria Hospital.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXLIII.—THE TREATMENT OF INSOMNIA.

I.—General Considerations.[1]

Insomnia, or the inability to secure a sufficiency of normal physiological sleep under favourable external conditions, is often one of the most exacting problems which confronts the physician. A sufficiency of physiological sleep denotes an amount which is normal and usual for a particular individual, although the actual duration and depth of sleep may vary with age and personal constitution. Insomnia implies not only inadequate sleep, but also failure to obtain sound and restful sleep. Three types of insomnia may be distinguished: (1) sleep delayed in onset; (2) sleep interrupted by disturbing dreams or "starts"; and (3) sleep normal in onset, but the sleeper awakens in the early hours of the morning and is unable to sleep again (internocturnal insomnia). Two of these types may be combined in the same patient.

In dealing with any case of insomnia, it is essential to regard the sleeplessness merely as a symptom and to use every endeavour to ascertain the exact nature of the underlying disturbance responsible for its production. Cases of insomnia have been differentiated into two groups: (1) secondary insomnia, in which the loss of sleep results from some form of bodily discomfort—e.g., pain, cough, dyspnœa, &c.; and (2) primary insomnia, in which no definite physical cause for the symptom can be found. In the latter, however, the sleeplessness almost invariably results from some psychical cause, often an alteration in the affective or emotional state of the patient (anxiety, fear, depression) which acts as a persistent mental irritant preventing the onset or interrupting the tranquillity of sleep. It is probable, indeed, that no true primary insomnia ever occurs.

Ætiology.

From the ætiological standpoint the main factors responsible for insomnia may be classified as follows:—

(A) *Physiogenic causes.*—Insomnia resulting from physical discomfort or organic disease.

(1) *Pain.*—Neuralgia, neuritis, arthritis.

(2) *Dyspnœa.*—Cardiac disease, asthma, nasal obstruction.

(3) *Cough.*—Bronchitis, phthisis.

(4) *Frequency of micturition.*—Cystitis, prostatic enlargement, disseminated sclerosis.

(5) *Pruritus.*—Skin diseases.

(6) *Pyrexia.*—Acute specific fevers.

(7) *Gastro-intestinal disturbances.*—Flatulence, palpitation, colitis.

(8) *Circulatory disturbances.*—High blood pressure, cold feet (peripheral stasis).

(9) *Toxic states.*—Chronic sepsis, alcoholic delirium.

(10) *Organic cerebral disease.*—Encephalitis lethargica, meningitis, dementia paralytica.

In some diseases insomnia may result from a combination of several of the above factors—e.g., in pneumonia from cough, dyspnœa, and toxæmia, or in typhoid fever from gastro-intestinal disturbance, toxæmia, and pyrexia.

(B) *Psychogenic causes.*—Insomnia in which no definite physical basis is found.

(1) *Anxiety states* (anxiety neuroses and anxiety hysteria).—Mental conflicts, apprehensions, disturbing dreams.

(2) *Neurasthenia.*—States of fatigue.

(3) *Hysteria.*—Auto-suggestion, somnambulism.

(4) *Compulsion neuroses.*—Obsessions.

(5) *The psychoses.*—Manic-depressive states, paraphrenia.

(6) *Dementia præcox.*

(7) *Confusional states.*

[1] The concluding portion of this article—Therapeutic Measures—will appear next week.

Clinical Aspects of Insomnia.

In dealing with any patient complaining of sleeplessness, a full physical examination is imperative at the outset. Apart from cases in which the symptoms point to an obvious cause—e.g., pain, dyspnœa, pruritis, frequency of micturition, &c.—the digestive, circulatory, respiratory, and excretory systems must be examined, the blood pressure taken, and, lastly, careful attention devoted to the investigation of the nervous system in order to exclude the presence of organic disease. Insomnia is often an early symptom of organic nervous conditions; for instance, in spite of what the name implies—encephalitis lethargica frequently begins with sleeplessness on several successive nights or, preceding the lethargy, insomnia may be associated with mild nocturnal delirium. Inability to sleep may also persist long into convalescence, especially in the Parkinsonian type of the disease, while it is quite common to meet with alterations in the sleep rhythm (the so-called "sleep-reversal") in which the patient is able to sleep quite well during the day, but insomnia occurs at night. The writer has met with several cases in which, the patient apparently having recovered from the encephalitis, a reversal of sleep rhythm was the only remaining symptom. Again, in general paralysis of the insane (dementia paralytica), insomnia frequently occurs in the early stage of the disease and may or may not be accompanied by excitement or exaltation. Later, in many cases, sleep tends to become excessive and even narcoleptic attacks may occur. Of the diseases of the nervous system associated ætiologically with alcohol, delirium tremens is accompanied by absolute sleeplessness in the early stages, while in alcoholic pseudoparesis insomnia is early and pronounced.

Anxiety.

When all physical factors have been definitely excluded and the conclusion reached that the insomnia is one of psychogenic origin, the physician's duty is to investigate all possible causes of mental anxiety. Consequently a full exploration of the patient's domestic, business, social, and sexual life is essential. A mental conflict is the basis of all cases of anxiety hysteria, in which insomnia is one of the most frequent symptoms. In such cases sleep is often disturbed by harassing dreams, usually associated with or symbolical of the factors giving rise to anxiety—e.g., the battle dreams of war neuroses, &c. Later, sleep is also delayed, the patient frequently anticipating the recurrence of disturbing dreams and fearing to fall asleep. The explanation of these phenomena advanced by analytical psychology is that painful or terrifying experiences are repressed; during sleep, however, control over the repressed memories is relaxed and the patient dreams of them either in actual or in symbolical form. Sleep may also be delayed in onset by the conflicts of apprehension, grief, or of business and domestic worries. Anxieties which have been partially obscured by the ordinary occupations of the day, or by attempts at a process of conscious repression, will emerge with excessive insistence and will have full play while the patient lies waiting for sleep to come. Under such circumstances all doubts are exaggerated and all worries intensified; sleep may eventually supervene only to be interrupted by a startling dream in which the anxiety is reproduced with added intensity and the awakening accompanied by distressing emotional manifestations, such as palpitation and sweating. During the stage of semi-consciousness that actually precedes sleep, the patient is sometimes rudely aroused by an apparent vision of startling intensity (hypnogogic hallucinations), and usually connected with his mental conflict, although often in distorted symbolical form; sleep is thus further delayed, if not actually abolished for that night.

Neurasthenia.

Neurasthenia is a term that should be confined to the clinical entity characterised chiefly by rapid and undue fatigue on slight exertion, physical or

mental, and should not be confused with anxiety neurosis nor anxiety hysteria. In neurasthenia sleep is often good, although it is occasionally delayed in onset. Almost invariably, however, the patient awakes unrefreshed, and is often difficult to arouse in the morning. Sleep may be disturbed by nocturnal emissions. Overwork, in the absence of coexisting worry, is a rare and doubtful cause of insomnia. Most cases in which the symptom is attributed to this factor are examples of anxiety states, mild manic-depressive psychoses, or early dementia præcox. Complete insomnia—total sleeplessness on a succession of nights—is very rare, but may occur in association with neurasthenia. In women it sometimes follows the prolonged nursing of invalids, during which period the absence of regular rest has lowered the general health of the patient and destroyed the normal sleep-habit. As this form may endanger mentality, prevention is better than cure.

Hysteria.

Sleeplessness is occasionally a purely hysterical manifestation (conversion hysteria); in such cases the degree of insomnia is often much exaggerated, the patient taking a delight in telling people how little he or she sleeps. Apart from the fundamental psychoneurotic disturbance, hysterical insomnia develops as the result of auto-suggestion, and may disappear quite suddenly, only to reappear in another form—e.g., as hysterical aphonia, headache, astasia-abasia, &c. In some cases the actual origin of the sleeplessness has been physical—for example, pain, &c.—but the cause, having disappeared, the insomnia persists as a hysterical symptom. This occurrence is analogous to the paresis that sometimes persists in hysterical form following an organic paralysis due to nerve injury, the actual lesion, as shown by normal electrical reactions, having recovered. Somnambulism —though not strictly a form of insomnia—may also interrupt the otherwise normal sleep in hysterical subjects. As a rule, the patient has no recollection of somnambulistic acts when awake.

Hypochondriasis.

In hypochondrical subjects insomnia may become a veritable obsession and constitute a definite "compulsion neurosis," the patient believing that under any circumstances it is quite impossible for him to sleep. Apart from hypnotics such cases may require prolonged psycho-analysis to elucidate the cause, and even then relief may not be attained. Similar cases, however, will eventually sleep quite an adequate number of hours, but will continue to assert that they do not sleep.

The Psychoses.

Insomnia is frequently an early symptom in the psychoses, occurring in association with the depressed or excited mental condition of manic-depressive states, in confusional psychosis, dementia præcox, presenile depression, &c. Many examples of persistent insomnia associated with depression are in reality cases of manic-depressive psychosis. To the same class belong the instances of suicide attributed to sleeplessness, some of which if recognised earlier might have yielded to treatment. In such depressed states sleep is considerably delayed, the patient lying awake, tormented by melancholy and painful ideas; sleep may also be disturbed by confused dreams, and the patient awake early, fatigued and depressed. In mania, excitement interferes considerably with sleep, and some acute cases are almost completely sleepless. Milder cases suffer from delayed sleep and usually awake too early, although when actually asleep their slumber is often profound. Apart from depression, some cases of senile insomnia are due to flatulence and some to high blood pressure. Many of the aged, however, although sleeping only four or five hours at night, will take naps during the daytime, and so average an adequate amount of sleep in the 24 hours.

THE UNIVERSITY OF LONDON:
ITS PRESENT CONSTITUTION AND MACHINERY.

BY PERCY M. WALLACE, M.A. OXF.

II.*

THE Senate of the reconstituted University met for the first time on October 24th, 1900. Seven months earlier, very shortly after the promulgation of the new Statutes and Regulations, but actually in anticipation of their formal approval by the Queen in Council on June 29th, an arrangement had been concluded between the Government and the Senate of the old dispensation by which the head-quarters of the University were transferred from Burlington Gardens, where they had been housed since 1870, to the Imperial Institute Buildings at South Kensington. The main central portion of this structure, including the chief entrance, the Marble and Great Halls, the rooms in the tower, and the whole of the east wing, were appropriated to the use of the University; and the new Senate on entering upon office found at their disposal accommodation which it was hoped would prove adequate for their enlarged administrative needs and for the holding of a considerable proportion of their examinations.

Lines of Development.

Their first task was to complete their constitution as laid down in the Statutes and Regulations, so that the full machinery of the University might be set in motion without delay. Fortunately, the Senate contained a large proportion of men and women not only keenly interested in the problem confronting them but also intimately acquainted with the methods and details of University administration. The Chancellor, the Vice-Chancellor, and the Chairman of Convocation, statutory members of the three Standing Committees, were all Fellows of the University,[1] and in that capacity had for some years taken a full share in its government. There were ten other members who were Fellows; the sixteen representatives of the Faculties had all had responsible experience of academic administration in connection with the Colleges and other institutions at which they held their posts; and of the remaining members there were very few who were not similarly qualified in greater or less degree.

Committees were at once appointed to consider the most urgent problems, and in the course of the first eighteen months these were sufficiently dealt with to enable the University to develope fruitfully along the lines prescribed in the Statutes. But fresh requirements and opportunities continued to demand their attention, and have so continued down to the present date, with the result that the Senate now control an organisation far more extensive and elaborate than the Commissioners could reasonably have envisaged in 1900. From the nature of the case these developments have come into operation under varying conditions—sometimes independently, sometimes by a process of mutual reaction; sometimes owing to external benefactions, sometimes through the natural thrust of the normal work—and all that can here be profitably attempted is to indicate briefly the most important and significant items in the process of the evolution of the University during the past twenty-seven years. The summary that follows observes no strict chronological order, but deals with accomplished facts at the conclusion of the period under review.

* Part I. appeared in THE LANCET last week.

[1] Up to the date of reconstitution the Senate consisted of the Fellows; these now retain their title, but not their seats on the Senate.

In spite of the continued abstention of the four Inns of Court, the Senate resolved in 1905 to constitute the Faculty of Laws which the Commissioners under the Act of 1898 had reluctantly felt themselves unable to bring into immediate existence. Provision for instruction in this subject had increased during the proceding five years, and the first roll of the Faculty contained the names of eleven persons teaching at University College, King's College, and the London School of Economics. By this step, taken after prolonged consideration, and at the earliest moment which appeared to them justifiable in all the circumstances of the case, the Senate removed the most striking defect in the new constitution which the University received in 1900—the absence from its curriculum of adequate opportunity for the systematic and philosophical study of the various aspects of Jurisprudence, which has for many centuries been regarded as an essential feature of the Universities of western civilisation.

Incorporation of University and King's Colleges.

Within the first decade of its reconstitution the *personnel* and property of the University received two notable augmentations which of themselves did much to give it an established position as a teaching body. In 1907, after five years' negotiations, University College, founded eighty years before with the title "University of London," but receiving its Charter under its more restricted designation, abandoned its old independence and became incorporated in the University, its whole organisation being transferred to the direct control of the Senate, with the exception of such departments and endowments as belonged to or were held in trust for its Hospital and the Medical School attached thereto. These were placed under separate administrations, the Medical School becoming a School of the University in the Faculty of Medicine on the same lines as the other great medical schools of London, except that the University took over the control of preliminary and intermediate medical studies on the College premises. Three years later a similar scheme was adopted with reference to King's College (including King's College for Women, subsequently transferred from Kensington Square to the Strand, but not the Household and Social Science Department of that College, which retains its specially erected premises on Campden Hill); in this case the Theological Department was also excepted from the general incorporation, and still remains under the government of its own Council as a School in the Faculty of Theology.

It may conveniently be mentioned here that among other institutions under the direct control of the University are the Brown Animal Sanatory Institution,[2] Goldsmiths' College, the Francis Galton Laboratory for National Eugenics, the Bartlett School of Architecture, and the Institute of Historical Research.

More Recent Admissions.

Though applications by institutions for admission to the status of Schools have always been granted only after the most minute investigation of their condition, purpose, scope, government, resources, and equipment both personal and material, the following have since 1900 been added to this category (in some cases only in certain subjects or for limited periods):—Westfield College, the London Day Training College, and the School of Oriental Studies in the Faculty of Arts; the Household and Social Science Department of King's College for Women in the Faculty of Science; East London College in the Faculties of Arts, Science, and Engineering; the London School of Economics (already a School in the Faculty of Economics) in the Faculties of Arts and Laws; Birkbeck College in the Faculties of Arts and Science; the Imperial College of Science and Technology (comprising the old Royal College of Science, the Royal School of Mines, and the old Central Technical College of the City and Guilds of London Institute, now bearing the title City and Guilds Engineering College) in the Faculties of Science and Engineering; and in the Faculty of Medicine the London School of Tropical Medicine, the Lister Institute of Preventive Medicine, the Royal Army Medical College, the Royal Dental Hospital and School of Dental Surgery, the Naval Medical School of the Royal Naval College (Greenwich), the Maudsley Hospital, Bethlem Royal Hospital, and the School of Pharmacy. Of the original Schools in the Faculty of Theology, Hackney College and New College have been merged into one under the title Hackney and New College, and Cheshunt College has ceased its connection with the University in consequence of its removal to Cambridge.

It will be observed that some of these more recent "Schools" in the Faculty of Medicine have been promoted from the list of "Institutions" given last week; to that list there has been added (among others not of special interest to readers of THE LANCET) the National Institute for Medical Research.

Professoriate and Lectorate.

The stages by which the University Professoriate and Lectorate have been established and developed (these constitute almost entirely the roll of the Appointed as contrasted with the Recognised Teachers) are so various and complicated as to preclude precise and detailed summary in this place. A large proportion of these posts owe their creation to the benefactions of individuals or corporations having no direct connection with the University; many to endowments supplied by the governing bodies of its own Schools who undertook to provide, in suitable cases, the minimum salaries prescribed by the Senate in consideration of the appointment by the University of a Professor or Reader holding his or her commission direct from itself; in other cases the Senate have, in recognition of individual distinction, conferred one or other of these titles on existing members of the staffs of Schools or Institutions.

The total number of Professors at the present time is 169; of Readers, 88. Of the Professorships 53, and of the Readerships 14, are held, under the Senate, at Schools in the Faculty of Medicine (including for this purpose the Departments of the two Incorporated Colleges that provide instruction in preliminary and intermediate medical studies). Of the five Professors of Medicine, four—those holding their posts at the Medical Schools attached to the London, St. Thomas's, St. Bartholomew's, and St. Mary's Hospitals—are also the Directors of the Medical Clinics of those Hospitals respectively; the Professors of Surgery at the Medical Schools attached to University College and St. Mary's Hospitals are also the Directors of their Surgical Clinics; and the Professors of Obstetric Medicine at University College Hospital Medical School and of Obstetrics and Gynæcology at the London School of Medicine for Women are respectively the Directors of the Obstetrical Unit at the former and of the Obstetrical and Gynæcological Unit at the latter. There are also Professors of Anatomy at eight of the Medical Schools, of Morbid Anatomy at one, of Bacteriology at three, of Bio-chemistry at three, of Chemistry at three, of Embryology at one, of Helminthology at one, of Pathology at eight, of Pharmaceutics at one, of Pharmacology at one, of Physics at four, of Physiology at six, of Zoology at two; and Readers in Anatomy at one, in Bio-chemistry at one, in Biology at one, in Chemistry at one, in Histology at two, in Medical Entomology at one, in Medical Protozoology at one, in Pharmocognosy at one, in Pharmacology at one, in Physics at one, in Physiological Chemistry at one. In this enumeration, as in analogous cases, I have confined myself to the Schools in the Faculty of Medicine. But these will serve as illustrations, reflecting the greatest credit on all the parties concerned, of the confidence felt throughout the Schools of the University generally in the sympathy and intelligence which have

[2] This dates from pre-reconstitution days, having been founded in 1871, and may thus be regarded as the pioneer of research work within the University.

characterised the increasing control by the Senate of appointments to the higher posts on the staffs of independent organisations, jealous of their natural rights and proud of their honourable record.

Boards of Advisors.

This gratifying relation between the Senate and the governing bodies of the Schools in the several Faculties has been in great measure due to the establishment of what is generally considered to be one of the most efficient features of the administrative system of the University—the Boards of Advisors. These are, of course, not wholly a novel creation, but in the special form in which they have been constituted in this University they have met with exceptional success. The Regulations governing this matter are necessarily complicated, as in some cases the posts in question are not attached to any particular School or Institution, in others are so attached and the salary is provided by the University, in others are so attached and the salary is provided by the School or Institution itself; in others again it is a question of the conferment of the title of Professor or Reader on a man or woman who is already a Recognised Teacher on the staff of some School or Institution. But for the sake of illustration it will be sufficient to take the common case where the post is tenable at a particular School and the salary is provided, wholly or in part, by the University. There has in the first place been established a permanent (though periodically revised) body of External Experts, persons having no other official relation with the University—three for each of over fifty subjects of University study which correspond generally, but in more specified detail, with those that give their titles to the Boards of Studies enumerated last week and to be further mentioned below. For this purpose the Senate have been fortunate in securing, on the special nomination of the Boards of Studies, the co-operation of a very large number of the leading authorities on the several branches of study throughout the British Isles—many of them occupying Chairs at other Universities. When a particular post is to be filled, a "Board of Advisors" is appointed, consisting of the Vice-Chancellor, the Principal, the three External Experts in the subject concerned, and four persons nominated for this particular case by the School to which the appointee is to be attached. The Board so constituted is permitted to advertise the post or not as it thinks fit, and in recommending any person for appointment by the Senate is directed to have regard to his contributions by research to the advancement of science or learning, to his powers as a teacher, and generally to his eminence in his subject or profession. To put the matter more bluntly than could with propriety be embodied in the Regulations, the External Experts are relied upon to guarantee, in the case of each man reported as eligible, that his professional status is adequate for the post in question, and the colleagues with whom he will be most intimately associated have the opportunity of indicating among those so guaranteed the individual with whom they would find it most congenial to work. The report of the Board is sent simultaneously to the Academic Council and to the governing body of the School at which the post is tenable, finally reaching the Senate together with the reports of these two bodies; and no appointment is made without the concurrence of the latter, as the authority most directly concerned. This procedure is adopted with the appropriate modifications when the post in question falls under one of the other categories indicated above, or when the matter in hand is the conferment of a title rather than the appointment to a Chair or Readership. Other Regulations under this heading are designed to secure suitable conditions of tenure and adequate leisure, equipment, and assistance for the prosecution of research. The minimum salary for a whole-time Professor is £1,000, and for a whole-time Reader £500; but in many cases the salaries actually paid are considerably higher—thus, for instance, Professors at Medical Schools who are also Directors of Clinical Units each receive £2,000.

The original roll of Recognised Teachers was, as has been already stated, constituted by the Commissioners themselves with a total membership of 440 men and women. Many of these have in course of time been promoted to the rank of Appointed Teacher, though this category consists to a large extent of persons brought on to the University staff from outside. The total number of Recognised Teachers at the present time is about 860, of whom 362 are registered as holding their posts at one or other of the Medical Schools. Medicine thus—for reasons already given—retains its numerical preponderance in the *personnel* of the University. But, except for what may be for this purpose regarded as one-subject Faculties (Theology, Laws, and Music), the staffs of the Schools and Institutions generally have grown to a noteworthy degree during the past twenty-seven years. This increase has been in great measure due, not only to the natural ambition of the Schools to make provision for their ever more numerous students, but also—and this applies specially to the growth of the Professoriate and Lectorate staff—to the intensified specialisation of the several subjects of the University curricula. Posts are now created in departments and even sub-departments of branches of study which until a comparatively recent date were deemed susceptible of adequate treatment by one man.

Increase in Boards of Studies.

This tendency, which is properly and indeed inevitably consequent upon the continuous cleavage of all progressive investigations, has been increasingly reflected in the number of the Boards of Studies. It will be remembered that the Commissioners had recommended the early constitution of thirty-two specified Boards. Of these it was decided to postpone for the present those in Archæology and Palæography, Laws, Pharmacy, Ethnology, and Marine Engineering and Naval Architecture; but the other twenty-seven were constituted with all speed—actually on December 19th, 1900, within two months of the first Meeting of the Senate under the new dispensation. The total membership of these twenty-seven original Boards was 374 (305 Teachers and 69 external experts). Year by year, as the development and specialisation of the work of the University demanded, the existing Boards have been enlarged, re-cast, and divided, and new Boards have been created, until at the present time the Register contains no less than forty-five, with a total membership of 1196 (986 Teachers and 210 external experts).[3] It is both interesting and significant to note the precise nature of these adjustments of and additions to the ultimate sources of expert guidance in the complicated fabric of the University. The Board of Laws was constituted in 1905, contemporaneously with the corresponding Faculty to which reference has been made above. Three of the others specified by the Commissioners have also been established—Pharmacy, Archæology and Palæography, and Ethnology, though of these the second bears the sole title Archæology and the third has been re-named Anthropology. Marine Engineering and Naval Architecture is thus the only definite "subject of University study" designated by the Commissioners as requiring a separate Board of Studies which has not yet found its place in the London curriculum. On the other hand, Mediæval and Modern Languages and Literatures has proved, both in scope and in treatment, too extensive an area for effective control by one Board, and has accordingly been subdivided under three, which deal respectively with the languages and literatures of the English, the Romance, and the Germanic peoples. Similarly, Physiology and Psychology form now the provinces of separate Boards; as do also Architecture and Fine Art. In addition, there are now in operation ten Boards not contemplated by the Commissioners—

[3] In both categories some members have seats on more than one Board.

Human Anatomy and Morphology, Veterinary Science, Sociology, Pharmacology, Statistics, Horticulture, Slavonic Studies, Comparative Philology, Military Studies, and one which has for its purview "the Principles, History, and Method of Science." This last-named, constituted four years ago, was with special and prolonged care designed to embrace not only the natural and mathematical sciences but also logic, ethics, history, pedagogy, economics, linguistics, archæology, scholarship, and medicine. The inclusion of so wide a field within the purview of one Board might at first seem to indicate a reaction against the spirit of specialisation; but the Senate were actuated by the recognition that the labourers in all fields of scientific enquiry are members one of another, and that a comprehensive consideration of the fundamental principles, the methods, and the progress of trained investigation is in itself a specialised industry, properly and profitably to be constituted a subject of separate study—the higher strategy in the campaign waged by the University against ignorance and narrowness of outlook.[4]

Maintenance of Standard.

It must not be supposed that this remarkable increase both in the number and still more in the *personnel* of the various bodies that constitute the framework of the reformed University implies any degradation of standard. On the contrary, the successive records of the Senate bear ample witness to the cautious elaboration of the machinery employed, whether imposed by the Commissioners or designed by themselves, and to the scrupulous care with which appointments and admissions are eventually made. And it is eminently satisfactory to learn that this jealousy for the honour of the organisation entrusted to its care has won the admiration of the various authorities, whether within the University or without, who have come under its operation. Admission to the status of a School is an honour which several governing bodies have been glad to achieve by providing the required additional outlay upon libraries and other equipment, and many a Teacher in Institutions throughout the metropolitan area has owed his increased salary or his restricted hours of work or his improved facilities for research to conditions imposed by the Senate upon his employers who had applied for his recognition.

The history of the Faculties during the period under review has not been in all respects what the Commissioners appear to have contemplated. As advisory bodies they have to a certain extent fallen between two stools. The Boards of Studies are more intensively expert in the details of curricula and the qualifications of Examiners, and the Councils are in a stronger position in matters that concern the more comprehensive co-ordination of studies. Moreover, the Councils must consult the Boards of Studies, but need not consult the Faculties unless they desire, though every Board must communicate to the Faculty or Faculties with which it is in relation the text of any report which it sends to either of the Councils. A further difficulty arises from the structure of the Faculties themselves. In the cases of Theology, Laws, Music, and Economics, the Faculty is hardly more (sometimes even less) than the corresponding Board of Studies without the external experts who sit upon the latter; in a modified degree this is true also of Engineering, where three Boards are concerned; on the other hand, in Arts, in Science, and especially in Medicine, the Faculty is far too large for the regular and convenient consideration of detailed business.[5] This disadvantage in the case of the three last-named bodies has led to the establishment of Faculty Boards, each consisting entirely or almost entirely of representatives appointed *ad hoc* by the associated Boards of Studies; these bodies are summoned as required, and are in some cases able to assist the higher authorities with correlative advice on the business of the Faculty itself, midway between the restricted sphere of the Boards of Studies and the more extensive purview of the Council. But there is a general feeling that these Faculty Boards are of the nature of a fifth wheel to the original coach, and that the urgent need—all legitimate interests being adequately safeguarded—is for the speeding up of the rate of advance rather than for any addition to an already inevitably cumbrous procedure. Thus the greatest influence regularly exercised by the Faculties themselves is in their capacity as electoral bodies. On their sixteen representatives on the Academic Council lies almost wholly the responsibility of digesting, correlating, and laying before the Senate all schemes, amendments, and developments affecting the Schools and Institutions, the Teachers (Appointed or Recognised), and the curricula, examinations, and degrees of Internal Students.

But the purview of the work of the University in this department has extended far beyond the immediate regulation of courses leading to graduation. Lack of space, however, precludes more than the barest mention of some of these newer features. To the Brown Animal Sanatory Institution, Goldsmiths' College, the Francis Galton Laboratory for National Eugenics, the Bartlett School of Architecture, and other foundations incidental reference has already been made; there is in each Faculty an elaborate system of Advanced Lectures delivered every year by some of the leading scholars and scientists of Europe and the United States; facilities for post-graduate study and research, and for the publication of their results and of students' theses, are constantly provided as far as possible; a series of carefully guarded Diplomas has been instituted in a variety of subjects—Anthropology, Geography, Journalism, Fine Art, Librarianship, Theology, Town Planning and Civic Architecture, Town Planning and Civic Engineering, Social Administration, and others; Libraries of all kinds, general and sectional, have been established and enlarged; and other illustrations, particulars of which may be found in the Annual Reports and other publications, show how fresh demands have ever met with fresh and fruitful response.[6]

Concentration of Preliminary Studies.

With all this record of achievement and advance there is one failure that calls for mention—or, if not failure in the strict sense, one instance in which the Senate have not been able to carry out in full a measure upon which the Commissioners laid special stress. In one of their Statutes they empowered the Senate, "with a view to greater efficiency and economy," to encourage among the Schools of the University the provision of common courses of instruction in suitable subjects, with consequent interchange of students; and added the direction:—"in particular the Senate shall use its best endeavours whenever practicable to secure such common courses of instruction for Internal Medical Students in the preliminary and intermediate portion of their studies under Appointed or Recognised Teachers at one or more centres." In an attached Report they pointed out how uneconomical was the system by which each medical school provided full instruction, not only in the strictly professional portions of the curriculum, but in Physics, Chemistry, Biology, Anatomy, and Physiology. The classes were small, the remuneration of the teachers inadequate, and the whole machinery an unnecessary burden upon the schools. The objections to concentration were frankly acknowledged—that it was essential that these subjects should be taught not as pure sciences

[4] Portions of this paragraph have been adapted to present conditions from the Report of the Principal Officer for the Year 1922–23.

[5] The membership of the several Faculties at the present time is as follows:—Theology, 20; Arts, 207; Laws, 20; Music, 17; Medicine, 405; Science, 242; Engineering, 60; Economics, 46. The Faculties of Arts, Medicine, and Science are concerned with the work of 21, 9, and 21 Boards of Studies respectively.

[6] It need hardly be added that many of these developments have been made possible only by the generosity of benefactors. I have not, either in this connection or elsewhere, been able to give any details of this most gratifying feature of the success that has followed the reconstitution of the University.

but with special reference to medical studies, and that great benefits resulted from continuous personal intercourse between teachers and students and the establishment of an *esprit de corps* from the beginning of the period of study. On the other hand were urged the disproportionate expensiveness of a system of small classes, each requiring elaborate equipment, the higher general standard of tuition that would accompany concentration, with eminent experts in charge of the several subjects, and the liberation in each school not only of space but also of human energy that could more profitably be devoted to clinical instruction. Weighing all the evidence before them, the Commissioners declared themselves in favour of concentration, but, failing to secure in this matter the support of the several medical schools, they were unable to frame Statutes to give compulsory effect to their views. Hence the Statute cited above is of a permissive and recommendatory character only; but the Report emphasises strongly the urgency of effecting such a concentration of teaching, and this not only in the specific "preliminary" and "intermediate" subjects indicated above, but also, should such an extension be found practicable, in Pathology, Pharmacology, and the various branches of Hygiene and Public Health.

As early as possible after they had got definitely to work, the Senate referred this portion of the Commissioners' Report to the Faculty of Medicine, who conducted an exhaustive enquiry into the whole question. After prolonged consideration of the views of three expert Committees, the Faculty declared their approval of the concentration of the preliminary and intermediate studies in two or more institutions; and on their advice the Senate prepared a detailed scheme for carrying it into effect, mainly by the erection, equipment, and endowment of an adequate and comprehensive Institute in the neighbourhood of the Central Office of the University. A large sum of money was collected for the purpose, and for a time the prospects of its realisation were most favourable. But as the details were further developed opposition arose among some of the Schools concerned, and eventually it was found that, owing to various apprehensions and difficulties of adjustment,[7] the scheme was no longer generally regarded as either desirable or practicable in the full sense of the Commissioners' Report. It had consequently to be abandoned, and the donations returned. This was a great disappointment to many who had believed, with the Commissioners, that the concentration they had recommended would have proved both efficient and economical. At a later stage it was adopted in a modified form by some of the Schools acting independently of the designed central control, and at the present time the students at Westminster, St. George's, Charing Cross, and King's College Hospitals are free to attend one of the University centres (University College and King's College) for instruction in their preliminary and intermediate work.[8]

But, if this particular application of the principle of common courses of instruction has for special reasons not been found practicable, analogous schemes have been, and continue to be, successfully adopted in other Faculties. As typical illustrations may be mentioned the concentration of Architecture, Dutch, and the Scandinavian Languages at University College, of Slavonic Studies at King's College, and of all Oriental Languages at the School of Oriental Studies; while Inter-collegiate Courses are conducted at various Schools in French, Italian, Geography, and other subjects, whereby the advantages anticipated by the Commissioners have to a considerable extent been secured.

External and Extension Work.

If in what I have written in these two articles I have confined myself almost entirely to the development of the Internal side of the University, it must not be supposed that I underrate either the importance or the progress of the other two main departments established on parallel lines by the Statutes of 1900. I have not attempted to sketch, even in outline, the history of the University at large during the past twenty-seven years. I have endeavoured rather to describe its fabric and machinery—to show what its constitution is, and how it has worked, both within the scope specifically appointed for it and by natural evolution beyond the immediate limitations of that scope. It was the new department—the Internal—that was then created, and that has since increased. The External side of the work of the University was in full and beneficent operation for half a century before the reconstitution of 1900, and—except for the establishment of the Boards of Studies—it has neither needed nor received any essential amendment since that date. As far as the readers of THE LANCET may be considered directly interested, it is sufficient to state that, *pari passu* with the Internal side (though with the necessary divergences), it has aimed at keeping abreast of the ever-increasing requirements of its province, whether by the adoption of Regulations dealing with fresh branches of specialised study, or by the periodical revision, at once cautious and sympathetic, of the list of Institutions (not only within these islands but throughout the Empire) from which, with the approval of the Privy Council, Certificates may be received, whether of courses attended or of appointments held, in connection with the several degrees in Medicine and Surgery. Its most notable development of recent years, that by which External Students are on request advised by experts with regard to their private work, to local facilities for education, and especially to means of relating their way of life to University studies, appeals from the nature of the case hardly at all to those seeking degrees in Medicine, however successful it has been in respect of other avenues to graduation.

For the same reason, and to a greater extent, the activities of the Extension Board do not fall within my present purpose. It has stood outside the elaborate machinery devised by the Statutes of 1900 for the regulation and co-ordination of the Internal and External Departments, and has thus been able with greater freedom to follow the lines of advance from time to time open before it. It has maintained with marked success the administration of University Extension work in London and the suburbs, having upon its Panel close upon seventy names, besides Supplementary Lecturers, and providing at about ninety centres continuous courses of lectures on History, Literature, the Fine Arts, Philosophy, and the various branches of Natural, Economic, Political, and Sociological Science. It is also concerned with the supply of Tutorial Classes for Working People throughout the metropolis; and has further within its province a carefully graded system of inspection and examination of secondary schools, the organisation of annual Summer Courses for Foreigners, and the award of a number of Diplomas and Certificates in subjects so diverse as Religious Knowledge, Psychological Medicine, Nursing, and Dramatic Art.

It is not, therefore, through negligence, but by the nature of my present limitations, that I have not dealt in full with these two departments, or at all with various other features of the work carried on by the Senate. My aim has been, not to dilate upon the character of the services which the University has rendered to the nation since its reconstruction, but to indicate under what system and by what agencies—with special reference to medical study—those services have been brought into operation.

[7] Among many other authorities, Lord Lister proclaimed himself as definitely hostile to the proposal.

[8] Mention may be made in this place—though there is no historical or organic connection between the two schemes—of the Physiological Laboratory which was established in the University Central Office in 1902 through the enterprise and devotion of a number of teachers of that subject. This was concerned, not with the instruction of undergraduates, but with the provision of advanced lectures and the prosecution of research; and had to be closed down in 1920 in consequence of the inability of the University to supply any longer the required accommodation by reason of the continuous increase of its own administrative staff. In this case also a large proportion of the donations had to be returned to those whose generosity had originally provided the equipment.

THE WORLD POPULATION CONFERENCE AT GENEVA.

AUGUST 31ST–SEPT. 3RD, 1927.

(FROM A SPECIAL CORRESPONDENT.)

THAT changes in the quality and quantity of the populations inhabiting the different countries of the earth have a fundamental bearing upon the future of the human race is obvious. Yet consideration of these changes has so far played but little part in those adjustments of international relations by which, in the last nine years, it has been sought to prevent wars. Hence the conference upon world population which sat in Geneva from August 31st to Sept. 3rd, attended by some 150 delegates from over 30 countries, has especial interest as being the first of its kind that has taken place.

In his opening address on Wednesday, August 31st, Sir BERNARD MALET, the chairman of the conference, made it clear that the objects of the conference were strictly impartial and scientific, and that propaganda was to be rigorously excluded from the debates. This statement of aim required emphasis, because it has been felt in some quarters that the promoters and most of the chief speakers of the conference were advocates of birth control, and that behind a façade of simulated scientific disinterestedness they had concealed the real motive of the conference—namely, birth control propaganda. The subject of birth control was therefore not discussed at the conference. So elaborately, in fact, was it avoided that certain aspects of the population question which, for the economist, possess scientific interest and which are rich in consequences for the racial future of mankind, were not touched upon.

The conference proper opened with a paper by Prof. RAYMOND PEARL upon the

Biology of Population Growth.

The substance of his argument was that the increase of the fruit fly, *Drosophila melanogaster*, and of yeast cells, grown under experimental conditions in bottles and test-tubes, could be graphically represented by a curve called, by its original discoverer, Verhulst, the "logistic curve." The multiplication of a wide variety of organisms, including human beings, was held by Prof. Pearl to conform to this curve.

But his exposition of the logistic curve was not devoid of ambiguity. Population growth is affected by three "primary variables"—natality, mortality, and migration. Upon these primary variables, however, there act "various secondary environmental factors," such as "food-supply, the economic situation, and social forces of various sorts." Now it is of the essence of Prof. Pearl's teaching that the influence of these secondary factors in modifying population growth is small. The chief difficulties of this argument can be conveyed by the following extract from Prof. Pearl's paper: It is not unreasonable to compare populations of fruit flies and human beings, because "populations, of whatever organisms, are, in their very nature, aggregate wholes, and behave in growth and other ways as such. The elements of their behaviour arising out of this condition of aggregate wholeness are just as true in populations composed of individuals of one species as in those composed of individuals of another. Perhaps the most impressive thing which has come out of the statistical study of human population growth is the evidence that the steady onward march of this growth is *not sensibly influenced by the host of economic and social events which are supposed of logical necessity, to affect it.*" (Italics mine.)

Two questions are raised by this quotation. In the first place, what, for human beings, is an "aggregate whole of population"? There is really no analogue, unless possibly that of a community living on a desert island cut off from the outside world, to be found among human beings for Prof. Pearl's bottled flies. What is the criterion of the "aggregate whole" of human population—the family, the tribe, the race, or humanity at large? Are the delimitations of the "whole" racial, cultural, economic or geographical in nature, or all simultaneously? Could, for instance, the British Isles, depending for its existence on its trade, be regarded as an aggregate whole in any sense comparable to the bottled colony of drosophila? The term "aggregate whole" clearly requires, but as clearly was not given, definition.

In the second place, what is meant by the statement that the growth of a population is not influenced by social and economic events? The industrial revolution was such an event. So was the agricultural development of the New World.

The trebling of the population of the British Isles in the last century is clearly attributable to these events. What, then, is meant by the statement that "secondary environmental factors," such as food-supply, have an influence which is "not sensible" upon population growth?

It was not surprising to find that Prof. Pearl's paper met with considerable criticism. This criticism for the first time reflected those differences in national attitude which were further manifested at every phase of the conference.

By American speakers, with their national leaning towards statistical and graphic formulations, the paper was hailed as a fundamental contribution which placed the problem of population growth upon a basis of scientific and mathematical fact. By speakers belonging to other nationalities, many of whom mollified their remarks by prefatory expressions of cordial personal esteem for Prof. Pearl, his paper was regarded, in its bearings upon human population, as a pseudo-scientific irrelevancy. The multiplication of flies in bottles, it was argued, protected from enemies and fed upon a controlled quantity of synthetic pabulum, had little bearing on the multiplication of human beings, or even of animals in a state of nature. It is probable that much of the criticism arose from misunderstanding, since Prof. Pearl was careful, in one part of his paper, to disclaim any desire to apply to human beings conclusions reached from observations on fruit flies. But in another passage he seemed to claim that his conclusions were applicable to human beings.

The next paper was read by Dr. H. P. FAIRCHILD, professor of sociology at New York University, upon the subject of

Optimum Populations.

His conception of the optimum population of a given country was that of a product of four factors, of which three are variable and one is fixed. "Land," used in the most comprehensive sense, is the factor which is fixed. Population, the state of the arts, and the standard of living are the factors which are variable. These terms were clearly defined by Prof. Fairchild whose thesis was that the criterion of the "optimum" of population should reside, not in the mere achievement of large numbers in relation to the available land and resources, but in a high standard of living, most helpfully considered in terms of family units. It is clear that the conception of an optimum population is fundamental to any effort to secure the fullest expression of social harmony and happiness within any community. Prof. Fairchild's paper served a valuable purpose in defining and sharpening this somewhat vague conception. His general thesis that the optimum should be conceived in cultural rather than in numerical terms, passed unchallenged.

Food and Population.

A paper on this subject was read by Dr. E. M. EAST, professor at Harvard University.

His argument was as follows: As far as can be foreseen at present, there exist on the earth some 13,000 million acres of tillable soil, capable of supporting, at the rate of 2½ acres per individual,

some 5000 million people. At the current rate of increase, this figure will be reached in about 100 years. At the present moment there exist in Europe some 80 to 85 million people who have to be fed with imported food. At present the only countries which make the exportation of food their primary business are Canada, the Argentine, and Australia. These countries are doubling their populations in 25 to 30 years, and are rapidly becoming self-supporting in the matter of manufactured goods in the meanwhile. Hence we are within measurable distance of a time when the present food-exporting countries will, after feeding their enormously augmented populations, have little food to export to the Old World and to Japan.

Hence it behoves these countries to become more self-supporting, either by increasing their food-production, or by limiting their numbers. Prof. East's conclusions were vigorously attacked by speakers from European countries, who seemed to treat him as if he were advocating American non-coöperation with Europe rather than prophesying from more or less incontrovertible data. The most ferocious onslaught came from Dr. Jean Bourdon, of the Sorbonne.

On the morning of Sept. 1st a paper was read by Prof. CARR-SAUNDERS, of Liverpool University, upon

Differential Fertility.

By this term is meant the varying rates of contribution to the adult ranks of the next generation made by different groups of the population. It was shown by this paper that in England those classes whose occupation is intellectual rather than manual, and those classes whose intelligence is shown by intelligence tests to be relatively superior, contribute less to the next generation than do the labouring classes and those classes whose intelligence, measured by intelligence tests, is seen to be of a relatively low order. Further, it was shown that this discrepancy in the contributions made by the different classes is increasing with the lapse of time.

Prof. Carr-Saunders was followed by Prof. LUCIEN MARCH, of Paris, Prof. GROTJAHN, of Berlin, and Prof. METHORST, of The Hague. These speakers described changes in their respective countries comparable to those that had occurred in England.

In a paper read on the afternoon of Sept. 1st, entitled Fertility and Sterility in Relation to Population, Dr. F. A. E. CREW, of Edinburgh, described the various factors which, affecting fecundity, fertilisation, pregnancy, and parturition, determine the reproduction rate of a given generation. The paper was of a non-controversial nature.

Other Papers.

Other papers were read by Mr. ALBERT THOMAS, who spoke in French, on International Migration and its Control, and by Mr. E. J. LIDBETTER, on Heredity, Disease, and Pauperism. These last contributions were in certain respects the most important of the conference. The painstaking investigations of the last speaker have led him to the conclusion that persons of low-grade stock conform in their marriages to the principle of "assortative mating." "The evidence," said Mr. Lidbetter, "suggests that defectives and low-grade types are closely intermingled and overlap, but that they preserve their general characteristics from generation to generation and *probably do not often, by intermarriage, initiate good stocks or derive strength from that source.* (Italics mine.) A few thousand family stocks probably provide the great burden of inherent defectiveness which the community has to bear." The fertility-rate of these types is high and Mr. Lidbetter says of them: "We may be assured that the rate of reproduction of these groups much exceeds that of any other section of the community." Further, they have not responded to that general rise in culture which has taken place in the last 100 years. During this period their "family conditions do not appear to have greatly altered, except that as their numbers have increased, they have not enjoyed that improvement in the standard of living which has been common, and the measure and intensity of their dependence upon the public has increased." This last observation has an important bearing upon the contention that these types are best helped by improving their environment.

Conclusions.

On the morning of Saturday, Sept. 3rd, it was resolved to form an international committee for the study of population problems.

It is difficult to sum up the achievements of the conference or even to draw attention to any conclusions upon which unanimity was reached. Certain delegates, especially those coming from Catholic countries, spoke as if they believed that the problems of population should be left to take care of themselves. Those who, for religious or other reasons, would let population problems take their natural course, usually give scientific expression to their beliefs by postulating "biological laws" through the operation of which nations wax and wane, the wealthier and more intellectual classes die out, and by which the other anomalies of differential fertility are to be explained. In face of such "laws" it is clearly useless, presumptuous even, for man to attempt to direct his biological destiny. Hence those who believe that "laws" govern population growth are usually opposed to eugenic ideals of racial improvement, and to the ideal of realising an "optimum" of population by any process of restriction or selection. This attitude was well represented at the conference by Prof. Corrado Gini, of the University of Rome. By speakers, on the other hand, from Anglo-Saxon countries and from Germany, it was generally believed that with the progress of knowledge and the enlightenment of public opinion it would be possible for man largely to regulate his biological future. To those who believe that, if civilisation is to be saved from disaster, "natural" selection must be replaced by "rational" selection, the ideal naturally commends itself that each country should strive to achieve a quantitative optimum—conceived along the lines indicated by Prof. Fairchild—with qualitatively optimal people. This last can only be realised by eugenic endeavour. It was interesting to English listeners, and doubtless agreeable to French listeners, to hear Prof. Grotjahn, of Berlin, state that the population of Germany is now approximately stationary, and outline for his country a detailed scheme of positive eugenics, concluding with the remark: "Then we should bring to an end the stupid fertility in those strata which have least means, room, or time for the upbringing of their offspring."

And it was noteworthy that the only suggestion that international pressure might eventually be brought to bear on a country to compel it to keep its population within limits compatible with the security of its neighbours, came from a Frenchman. In the words of Mr. Albert Thomas: "International rules concerning naturalisation and assimilation accepted by common consent, might, failing a policy of compulsory birth control, form a protection against excessive growth of certain sections of the world population where such growth may represent a danger to neighbouring communities."

PAPWORTH VILLAGE SETTLEMENT.—Dr. P. C. Varrier-Jones, medical director, in his report for 1926, stated that there were 127 children in the colony at the end of the year, of whom 81 were between the ages of 12 and 3. "After 11 years' experience," he writes, "no child (and some have now come of age) has, while a member of our community, contracted tuberculosis of the lungs, glands, bones, or joints, or indeed in any known clinical form. We have had no single case of tuberculous meningitis. Those who have left the settlement and seek education or employment elsewhere are all free from the disease." Dr. Varrier-Jones claims that this system has cut the vicious circle of infection, rendering the family not only free from infection but highly resistant to the disease.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Insurance not Charity.

IT is interesting to see that at the recent meeting of the Scottish Association of Insurance Committees the President should have found it necessary to say that, after 15 years of administration, perhaps the most evil of all the forms of opposition to national health insurance is that which may be frankly described as snobbery. Some young people, he said, would have nothing to do with the Act because they looked upon its benefits as a kind of charity or pauper relief.

The claim made in the early days for contributory insurance was that it was essentially different from "rates," and that the recipients of benefits valued them more because they had paid for them. This was even regarded as the groundwork of a better system of "moral responsibility," and was supposed to evade the social degradation which came from providing health organisation and service out of the rates. This delusion has gone by the board, and now even benefit under unemployment insurance is nicknamed—quite wrongly—"the dole," while all forms of benefit under this, or under the national health insurance, are regarded in the same impersonal way as the services of gas, water, electricity, and the public health service generally. Insured persons, notwithstanding the moral difference supposed to be generated by the contributory system, go indifferently to child welfare centres, out-patient departments, general hospitals, and maternity homes and hospitals. The result to the individual is much the same whether the tax be an ad hoc tax paid in a special way as contributions, or a local rate paid on the rental, or a tax paid on tobacco or on income. In the end he acts on the idea that he is getting something for nothing whenever he does not (as it were) pay coin over the counter for his requirements.

Reorganisation of the Board of Health.

One of the motions brought before the Association's annual meeting was :—

"That the Conference view with disquietude the proposals made by the Government in the reorganisation of Offices (Scotland) Bill, to the effect that the Scottish Board of Health should be abolished, and the work inter alia of national health insurance in Scotland conducted by a department under a secretary responsible to the Secretary of State for Scotland, and regard as necessary for the proper conduct of the Local Government in Scotland that the duties of supervision should be undertaken by a responsible Board situated in Scotland."

This motion seems to be founded on some misunderstanding. The existing Board is subject in everything to the President, who is the Secretary of State for Scotland, and the new organisation, whatever form it takes, will be in the same position. But the above motion was supplemented in a way that materially altered the effect of it. A motion was moved :

"That, in the event of the Government pressing for the abolition of the Scottish Board of Health, the conference instructs the executive to take such steps as are necessary to secure by amendment of the Bill, or otherwise, that the Department of Health, which will take the place of the Board, shall be established on the lines of the Scottish Education Department, so that the existing relationship between the Scottish Board of Health and the Secretary of State for Scotland can be maintained by the Secretary of State, as Minister, being the responsible head of the Department."

Sir Henry Keith, whose unrivalled experience in Scottish local government gives weight to his view, said there was no intention, so far as he understood the Bill, that the seat of office, so far as Scottish administration was concerned, should be removed from Edinburgh. If there were any such intention it would be strenuously opposed by all representative associations in Scotland.

In effect, the addendum and the motion together support the Government's proposals. The second reading of the Bill will be completed, it is understood, in the autumn session, and the Bill will be passed.

Sir John Lindsay.

By the death of Sir John Lindsay, late town clerk of Glasgow, Scotland has lost a man of great intellectual acquisitions and force of character. It is more than 30 years since I first met him at meetings of the Sanitary Association. He was heart and soul in favour of the modern public health movement, and when he ultimately became town clerk everybody realised his strength as a municipal administrator and reformer. He was an untiring slave in the service of the corporation and the nation, and his evidence before the Housing Commission was masterly. History, as yet, is not in the habit of recording what the commonwealth owes to men of this kind.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Tuberculosis Medical Officers' Association.

THE annual meeting of the Tuberculosis Medical Officers' Association was held in Dublin last week, and the Association added to its usual programme the holding of a scientific meeting to which members of the profession were invited. Dr. McMahon, of New York, showed an interesting series of X ray slides illustrative of the changes that take place in the lungs in the healing of pulmonary tuberculosis. Dr. Boyd Barrett, one of the medical inspectors of the Department of Local Government and Public Health, followed with a paper on the Control of Bovine Tuberculous Infection. He quoted investigations proving that bovine infection is the cause not only of human disease but of death. He said that it was necessary that facilities for the bacteriological examination of milk should be provided, and suggested the application of the Swedish law, which made it imperative that persons working in dairies or concerned with the sale of milk should be in possession of a medical certificate, delivered less than a year before the time of their engagement, stating that they were not suffering from contagious tuberculosis, with severe penalties and stoppage of sale of milk for non-compliance. Every dairy farm and dairy should be registered, and registration should be followed by inspection by a veterinary surgeon, so that all diseased animals might be discovered. In this way the elimination of advanced cases of tuberculosis could be commenced, leading subsequently to the separation of healthy from tuberculin-reacting cows. Thus, also, the basis would be laid for the ultimate objective of the rearing of tuberculosis-free herds. The next step would be the testing by tuberculin of the remainder of the herd, and next the milk of cows giving the reaction to tuberculosis should be tested for the presence of tubercle bacilli.

Dr. P. J. Burke, tuberculosis medical officer of County Sligo, read a short paper on the Costs of Tuberculosis. He quoted estimates to show that the average life lost to the nation by tuberculosis had been valued at from £500 to £1500 by different authorities. Taking £300 as a minimum figure, the cost of each illness terminating in death might be counted as £360. Each life lost, therefore, deprived the country of the value of at least £660. The reduction of tuberculous mortality in the year 1925 as compared with 1915 meant a saving for the nation worth £1,354,320. The cost to the nation for the year 1927 he estimated at £4,347,272, while the money at present spent on county tuberculosis schemes was about £75,000.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some 1926 statistics of six counties :—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Diarrhœa under 2 years.	Infant mortality.	Maternal mortality from childbirth.
Essex .. .. .. (991,700)	16·8	9·9	0·76	1·37	1·4	1·5	8·2	52	3·0
Surrey .. .. .. (773,900)	14·7	10·0	0·66	1·44	1·5	1·4	3·4	50	3·0
Warwickshire .. (370,600)	17·5	10·5	0·82	1·38	1·4	1·5	3·7	55	3·3
Leicestershire .. (279,700)	17·4	10·5	0·88	1·23	1·3	1·5	4·5	58	3·5
Cumberland .. (217,400)	19·9	12·6	0·76	1·42	1·9	1·8	9·7	72	6·2
Northamptonshire (214,200)	15·8	11·4	0·76	1·60	1·6	1·8	2·6	52	4·7

Essex.

Dr. W. A. Bullough states that the tuberculosis staff has been strengthened during 1926 by the appointment of Dr. W. Burton Wood as consulting officer (part-time) for pulmonary tuberculosis. Dr. Wood has visited all the dispensaries and sanatoriums in the county, and also the sanatoriums outside the county which receive Essex patients. The report contains a contribution from Dr. Wood on "tuberculous infection in early life," which concludes with the suggestion that special cards should be issued in order to facilitate the following up of children threatened with tuberculosis. He would use these cards for four classes of children : (1) those who had been contacts of cases of open tuberculosis ; (2) those who had suffered from any tuberculous disease ; (3) the so-called pre-tuberculous children ; and (4) those whose appearance suggested the type of constitution usually associated with a low resistance to tuberculous infection.

When these children left school the special card would be sent to the tuberculosis department at Chelmsford for future reference. The report also contains extracts from the report of Dr. J. Pearse, of the Ministry of Health, on the Essex combined medical service resulting from an inquiry made early in 1926. This scheme is an attempt to provide a unified public health service by appointing the local medical officer of health assistant to the county medical officer of health for the public health services performed by the county. Dr. Pearse's report is generally favourable as regards the availability of a specially trained officer, coördination, and the avoidance of overlapping. One officer residing in the district responsible for all public duties has the opportunity of wider influence. Dr. Pearse deals with some of the objections which might be met in various ways. Dual control has caused no special difficulty, though there is a feeling that the county council duties receive first consideration. Some of the districts are too big and others are too small. The salary of £700, even if it rises to £800, is not attractive as a permanency, and the question arises whether the future prospects of these officers are helped by the title of *assistant* county medical officer. The responsibility and salary do not perhaps compare favourably with those usual in the case of the medical officer of health of a combined district. The scheme now includes 12 areas and a population of about 448,000. In view of the new regulations for dealing with puerperal pyrexia, the county council have agreed to the appointment of an obstetric specialist to attend a limited number of cases, the total fees not to exceed £105 plus travelling expenses, for an experimental period of 12 months ; and have authorised the county medical officer to arrange for the admission to hospital of a limited number of patients at a cost not to exceed £3 3*s.* per week. The arrangements for home nursing, when required, are to be made with the Essex County Nursing Association.

Of 1356 samples of milk, 87 were unsatisfactory ; 28 contained added water, varying from 4 per cent. up to 44 per cent. ; 57 were deficient in fat, the deficiency varying from 5 per cent. to 43 per cent. ; and two samples were unusual in being dyed with annatto. The licences issued by the county council for Grade A milk show an increase year by year. During 1923 eight were issued, during 1924 11, during 1925 27, and during 1926 35. During the year "98 samples were submitted to microscopical examination, when four were found to contain bacilli indistinguishable microscopically from the tubercle bacilli." No further action is mentioned, so presumably the biological test was not carried out. Under the Tuberculosis Order 676 animals were slaughtered. Of these 318 had tuberculosis which was not "advanced" ; 356 had advanced tuberculosis ; and two were found to be not tuberculous. The total compensation paid was £4017 6*s.* 6*d.*, and the receipts from the sale of carcasses were £701 5*s.* 6*d.*

The county council is endeavouring to see that the water-supplies of the county are distributed equitably among the various districts. The rivers are to be gauged, beginning with the Stour, which appears to be the chief practical source of future supplies for the county.

Surrey.

Dr. Joseph Cates records two memorable happenings during 1926. The county sanatorium at Milford was begun, and a scheme to provide treatment for children under school age was approved. The sanatorium will accommodate 300 patients, and the contract price amounts to £166,270. Substantial progress was made by the end of 1926, despite the interruption caused by the general strike, and the building should be completed before September, 1928. In the scheme for the treatment of pre-school children a whole-time dentist is to be appointed and an additional health visitor to act as dental nurse. Arrangements will be made for the services of a part-time ophthalmic surgeon, and for children suffering from enlarged tonsils to be treated in hospital on the terms at present sanctioned by the Education Committee. To begin with, the larger and better equipped school clinics—such as those at Chertsey, Woking, Malden, and Surbiton—will be used for the scheme. Photographs of the Malden clinic are included in the report. The condition of the River Wandle has received considerable attention during the year. A detailed survey from Wandle Park, Croydon, to the London-road bridge at Wallington has been made. Pollution in this stretch is chiefly due to oil from the surface water system at Croydon. The removal of obstructions due to deposits and defective banks has diminished the danger of flooding. Two instances of chemical pollution, both originating in the Carshalton district, were dealt with.

Dr. Cates deals with the recognised relation of chicken-pox to herpes zoster, and suggests that, when it is found necessary to make chicken-pox notifiable, herpes zoster should be also notified. Owing to the apparently increased prevalence of acute poliomyelitis, the county council endeavoured to obtain particulars from the local sanitary authorities. Four of the latter refused to comply with the request, and the matter was referred to the Ministry for a decision. The county council is responsible for maternity and child welfare in a great part of the county, five municipal boroughs and some urban districts being excepted. The area included has a population of 450,670. The superintendent health visitor is

inspector of midwives, but the superintendent of the Surrey Nursing Association inspects the midwives in the employ of her association. The county council provides hospital treatment for children with ophthalmia neonatorum in preference to domiciliary nursing, but little use is made of this arrangement, the cases admitted to hospital during the last four years being 1, 1, 2, and 1 respectively. No cases of impaired vision were reported in 1926, and one in each of the two previous years, the notifications in each of these three years being about 50. For dealing with cases of puerperal pyrexia the county is divided into three areas. Each area has its gynæcologist and available hospital. During the first quarter of the year, under the new scheme, there were two applications from medical practitioners for a second opinion, and five cases were admitted to hospital. More requests for these facilities are expected when the scheme becomes more widely known. The council has no maternity homes of its own, but makes arrangements for the admission of patients to suitable homes, chiefly at Woking, Redhill, Guildford, and Bagshot. These homes are being used more every year, and the accommodation is now hardly sufficient to meet the needs of the county. The council have endeavoured to arrange for a "refresher" course for midwives lasting for a fortnight, but, as no institution in London was prepared to meet this need, an effort is now being made to arrange for such a course at the County Hospital, Guildford. Answers to a questionaire on the subject of overcrowding, addressed to the local authorities in the county, showed that in rather more than one-third of the districts there was some evidence that overcrowding was diminishing.

Warwickshire.

Dr. A. Hamilton Wood points out that of the 356 deaths of infants 176, or 50 per cent., were due to congenital debility, malformation, or premature birth, and he looks forward to antenatal instruction in the future through the obstetrician and the midwife as the means of preventing many of these deaths. At the present time, however, the antenatal work is on a very small scale. There were 6493 births in the county during 1926. The two principal antenatal clinics at the county maternity homes at Warwick and Rugby were attended by 164 expectant mothers, and two small antenatal clinics at Coventry and Stratford-on-Avon were attended by 23 expectant mothers.

The Coventry and Warwickshire Hospital and the Warneford Hospital at Leamington have antenatal clinics for the admission of complicated cases to their maternity wards. It thus appears that up to now only about 200 expectant mothers in the county receive antenatal supervision through these clinics. There were 14 notifications of encephalitis lethargica in the urban districts and 19 in the rural, and 21 deaths were registered from this disease. The Upper Tame Basin Joint Committee have improved the quality of the river water before it reaches the county, but a great deal still remains to be done. The trade waste from paper mills is found to be difficult to deal with. On July 27th a complete survey was made of the Avon and its tributaries. The pollution of the river by Leamington was worse during the summer owing to the pumping being interfered with by the coal shortage. The capacity of the pumps is to be increased and filter beds, capable of dealing with the whole of the town's sewage, are to be laid down. Rugby sewage works are giving improved results. The improvement from the work done at Coventry is not as great as was expected when the works were extended some two years ago, and the area available for bacterial filtration will need to be increased.

The measures taken by the county council to comply with the new Milk Act are to investigate all cases of tuberculous milk reported by outside authorities and to take 50 bulk samples with a view to the detection of tubercle bacilli. Ten notifications of tubercle-infected milk were received from outside authorities, but as the result only three tuberculous cows were found and slaughtered under the Order. Seventy-five per cent. of the births were attended by midwives, who sent for medical help in 990 cases out of 4887. The provision made to comply with the new puerperal pyrexia regulations consists of the admission of cases to the larger hospitals of the county at a charge of £3 3*s.* per week, pathological examinations by the University of Birmingham, and the appointment of obstetric consultants, one at Birmingham and the other at Leamington. By the Housing Act of 1926 the county council is empowered to take steps for the improvement and renovation of labourers' houses, but the district councils may apply to the Ministry for permission to administer the Act. Most of the district councils have so applied, and for the present the county council will leave the administration of the Act to the urban and district councils.

Leicestershire.

Dr. J. A. Fairer reports that Dr. T. Robinson had to resign on Sept. 30th on account of ill-health, after 28 years' service, and that he has been appointed consulting medical officer. Dr. Fairer has to record a widespread outbreak of infantile paralysis during the autumn, which makes "a comprehensive scheme of orthopædic treatment a matter of extreme urgency." The cases numbered 72, 55 being in the rural districts and 17 in the urban. A feature of the distribution of the cases was the relative immunity of the coal-mining districts of the western part of the county. The county council provides 15 beds at a convalescent home at Woodhouse Eaves for county children, of whom 92 were admitted during the year with very satisfactory results. The enormous development of housing schemes has led to new difficulties in sewage disposal. Serious pollution of rivers and streams is unavoidable during this period of reconstruction, and the difficulties, says Dr. Fairer, will have to be faced with foresight and determination. Improvements are being effected in the hygienic conditions of the elementary schools, especially with regard to cloakroom accommodation and the arrangements for drying clothes in wet weather. Six dairy farms were visited owing to outside complaints of tuberculous milk. On four of the farms no animal giving tuberculous milk could be detected, and the unusual suggestion is put forward that producers sending milk by rail do not always have their own churns immediately returned to them, that these churns may be used in the interval by other milk producers, and that the real owner of the churn may be blamed for tuberculous milk which he did not produce.

Northamptonshire.

Dr. L. Meredith Davies took over the duties on April 1st from his predecessor, Dr. Charles E. Paget, the first medical officer of health for the county, whose term of office extended from 1897 to 1926. Dr. Paget's recent death was announced on p. 682 of the last issue of THE LANCET.

Good progress has been made in the coördination of the health services, which, however, will not be complete until all the branches are housed in one building. In the future a single medical officer will supervise the health of the children from prenatal days until they leave school, and a single officer will deal with each family, except for tuberculosis or eye defects. The time saved will enable the schools to be visited every 12 months instead of every 14, and the work should be more efficient. The amalgamation of office staffs is under consideration, and also a scheme by which the same nurse will carry out health visiting and school and tuberculosis work. The county council have installed two mercury-vapour lamps at the Wellingborough dispensary, in order to ensure the treatment of all known cases of lupus in the county. Dr. Davies says the results of light treatment in lupus have exceeded expectations and that improvement is more rapid in the ulcerative varieties. "Dramatic results" are obtained in the case of discharging sinuses in connexion with various tuberculous conditions. The pre-tuberculous group shows distinct

improvement in mental health and brightness, with definite gain of weight. Under the definition "pre-tuberculous" he includes children with a history of exceptional exposure to infection and those who either present stigmata of tubercle or are debilitated, anæmic, or marantic, or have failed to recover completely from measles, whooping-cough, &c. With regard to pulmonary cases, much longer experience will be necessary before expressing an opinion, but good results have been obtained in a few carefully chosen cases. Vitaglass has been substituted for ordinary window glass in the children's wards of the sanatorium. Dr. Davies discusses the relation of tuberculosis to the boot and shoe industry. About 20 per cent. of the occupied workers are engaged in this industry, and the number of new patients at the dispensary, the number of patients admitted to the sanatorium, and the number of deaths of adults from pulmonary tuberculosis in the same industry are all about 25 per cent. of the respective totals. The finishers and the clickers are the workers chiefly attacked by tubercle. In the clicking department the air is stagnant but free from dust. In the finishing department the air is hot from gas jets and generally very dusty. In each case the work is sedentary and light. Outside complaints of tuberculous milk led to veterinary inspections at four farms and the bacteriological examination of 29 samples of milk, but no cows with tuberculous udders were traced. Up to now the county council have made no arrangement for the veterinary inspection of the cattle in the county, but have contented themselves with appointing the existing joint committees for veterinary inspection, which only cover a portion of the county, their agents.

Cumberland.

Dr. F. H. Morison refers to the unenviable notoriety of his county for a high maternal death-rate from childbirth. For its reduction he looks to antenatal work. There is no mention, however, of any antenatal clinics conducted by the county council. The Housing (Rural Workers) Act, 1926, has been considered. Several district councils wished to work the Act. The county council, however, decided that central administration was essential to secure uniformity of practice throughout the county. They have therefore drawn up a scheme, which has been approved by the Ministry, showing the conditions under which financial assistance will be given to the owners of small properties to enable them to effect improvements and renovations. Dr. Morison reports three outbreaks of diphtheria in which immunisation was apparently effective. In the first at Hayton there were 13 cases with four deaths. This outbreak was associated with a carrier, and cases occurred intermittently from August, 1925, until July, 1926. Ultimately all the school staff and children (whose parents gave consent) were Schick-tested and immunised. No fresh cases occurred subsequent to the inoculations, in spite of the fact that the carrier was in attendance at the school. The second outbreak, at Hallbankgate, occurred suddenly in the autumn of 1926. There were 11 cases with three deaths; 140 children were immunised, and no subsequent fresh cases occurred. At Brampton there were 13 cases with one death. About 240 children were immunised, and in this case two of the inoculated children subsequently contracted diphtheria. One of these children had only had one inoculation, and the second three inoculations, a month previous to the attack of diphtheria.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 17TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 126 (last week 146); scarlet fever, 1675; diphtheria, 1022; enteric fever, 104; pneumonia, 454; puerperal fever, 40; puerperal pyrexia, 79; cerebro-spinal fever, 8; acute poliomyelitis, 46; acute polio-encephalitis, 4; encephalitis lethargica, 23; dysentery, 8; ophthalmia neonatorum, 111. No case of cholera, plague, or typhus was notified during the week.

While the cases of poliomyelitis and polio-encephalitis are scattered over 16 counties in England and Wales, there is a high incidence of the infection in the East Riding of Yorkshire, where the numbers reported for the last few weeks (looking backward) are 20, 25, 20, 13, 8. From Kingston-upon-Hull itself 14 cases were reported this week against 21 cases last week. It is stated that the mortality has not been heavy.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 5 (0) from enteric fever, 13 (2) from measles, 6 (0) from scarlet fever, 8 (4) from whooping-cough, 27 (6) from diphtheria, 75 (22) from diarrhœa and enteritis under two years, and 24 (2) from influenza. The figures in parentheses are those for London itself.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. W. L. Hawkins is placed on the retd. list with the rank of Surg.-Capt.

Surg. Comdrs. C. A. G. Phipps and K. D. Bell to *President*, for Royal Victoria Yard, Deptford.

Surg. Lt.-Comdr. F. C. Hunot to be Surg.-Comdr.

The following appointments have been made by the Admiralty: Surg.-Lts. F. W. Gayford to *Foxglove*; T. S. Osborne to *Bruce*; H. J. Scott to *Cricket*; A. S. Burns to *Castor*; and T. F. Barlow to *Keppel*. Surg.-Lts. (D.) F. W. Watt to *Victory*, for R.M. Infirmary, Eastney; and D. L. Simpson to *Victory*, for R.N. Barracks, temp. supy.; and T. Hunt to *Ramillies*.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg.-Lt. R. S. Allison to be Surg.-Lt.

ROYAL ARMY MEDICAL CORPS.

R. Reynolds to be Temp. Lt.

ARMY RESERVE OF OFFICERS.

Lt.-Col. F. Harvey, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Capt. (Prov.) A. Badenoch is confirmed in his rank.
Lt. C. P. Oliver to be Capt.
Lt. D. R. Lewis resigns his commn.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. J. Lamberton from the Active List to be Capt.

ROYAL AIR FORCE.

The undermentioned are granted short service commissions in the rank of Flying Officer for three years on the Active List: G. T. O'Brien and P. O'Callaghan.

Flying Officer W. D. Guyler is promoted to the rank of Flight Lt. (Dental) on promotion to Capt. in the Army Dental Corps.

INDIAN MEDICAL SERVICE.

Capts. E. C. A. Smith, Kekhasru Sorabji Master, W. J. Webster, and S. R. Prall to be Majs.

Maj. G. Covell has been appointed Supernumerary Officer, Central Research Institute, Kasauli. Lt.-Col. D. H. Rai, professor, King Edward Medical College, has been appointed Civil Surg., Lahore, vice Lt.-Col. J. G. D. Swan. Sardar Sahib Dr. Amdik Singh has been appointed Officiating Civil Surg., Shahpur, vice Dr. Traynor. Maj. A. S. Fry to officiate as Officer Commanding Indian Military Hospital, Peshawar, vice Lt.-Col. G. C. L. Kerans, granted leave. Capt. L. G. Pearson to officiate as 2nd in Command, Indian Military Hospital, Peshawar, vice Maj. A. S. Fry, vacated. Capt. R. Sen to be 2nd in Command, Indian Military Hospital, Sialkot, vice Capt. D. P. Bhargava. Capt. D. Kelly to be in Command, Indian Military Hospital, Bakloh, vice Capt. R. A. Leembruggen, vacated. Maj. R. N. Khosla to be 2nd in Command, Indian Military Hospital, Lahore Cantonment, vice Maj. J. B. Hanafin, vacated. Col. W. D. A. Keys, Indian Military Hospital, Bangalore, to be Senior Brevet Colonel. Maj. J. Scott to be Brevet Lt.-Col. Lt.-Col. J. G. D. Swan, Civil Surg., Lahore, has been granted leave, and Maj. T. L. Bomford, Officiating Civil Surg., Burdwan.

Correspondence.

"Audi alteram partem."

THE BROAD ROAD OF HEALTH.

A REJOINDER.

To the Editor of THE LANCET.

SIR,—The MacAlister lecture, which I had the honour of delivering before the London Clinical Society in July last, has been the subject of a good deal of discussion, both in the correspondence columns of THE LANCET and elsewhere. In addition to the comments which have appeared in the medical and in the lay press, I have received a very large number of letters. The part of the lecture which has given rise to the greatest amount of discussion is that in which I said that the case for wholemeal bread had recently been overstated. I still maintain that this is so. In this letter I wish to draw attention to two considerations of a more general kind, arising out of the wholemeal bread propaganda in so far as medical men have taken part in it.

Before doing so, perhaps, it may not be out of place to refer to some of the criticisms which have been advanced against my view. I do not purpose a specific rejoinder. The full corroboration of my remarks in quick succession by several distinguished professors of physiology, by medical officers of health who had made a special study of the question, by the professor of agriculture at Cambridge University, and then by the chief medical officer of the Ministry of Health, renders this unnecessary. It also gives my contention that academic hall-mark which the President of the New Health Society, whilst generously granting me status in another direction, regretted that I lacked in this one. This overwhelming series of confirmations modified considerably the attitude of the Honorary Secretary of the Society, who, before they appeared, rebuked me severely for making statements so "unworthy" of myself, and afterwards suggested that, in view of the different medical opinions enunciated, the Medical Research Council should give the matter early attention. A most admirable adjustment and one which, were it maintained, would doubtless put the teaching of the Society above reproach.

Of my many other critics I need say little. Most of them have misread my main thesis, no doubt being influenced more by an unfortunate newspaper controversy and consequent detachment of some of my sentences from their context, than by reading the lecture itself. I can only explain the virulence of some of the letters I have received by supposing that I have unwittingly struck a blow at some vested interests. Two gentlemen called me a liar and one of them insistently invites me to debate this point on the platform. But a feeling of slight prejudice makes me doubt if such a discussion would serve any useful purpose. Certain firms have sent me boxes of elegantly packed biscuits and specimens of rather expensive bread, feeling sure (they say) that I did not know of the existence of these things or I should not have said what I did. I have been challenged to live by (white) bread alone, despite the plea that I entered for a mixed diet. The challenger offers to write my epitaph if I died, which I should deserve to do if I subscribed to his childish logic. And an appropriate epitaph would be: "I was well; I wanted to be better; here I lie." Mr. X. has told me how well his pigs thrive on wholemeal. Mr. Y. relates how his canaries wilt when fed on flour. I have not had time to remind the writers that a man is neither a pig nor a canary, so they are probably quite happy. And in any case my withers are unwrung, because Mme. Z., "dancer of originality," cheers me by the news that, though her age was 42 last May, she can perform the usual "lifts and swings," and follow her profession of "exhibition and semi-acrobatic dancer, without the slightest fatigue or distress," much better on white bread than she can on brown . . . .

Had the advocacy of wholemeal bread been confined to a statement of its virtues for particular individuals, or even to a recommendation of its use as an occasional alternative to white bread by those who are able to disregard the economic side of the question, I should never have said what I did. For I readily endorse both of these aspects of the matter. But to state that the substitution of wholemeal for white bread by the whole nation would result in such hygienic benefits as would amply compensate for the extra cost to the worker; to go further and promise that such substitution offered immunity from cancer and other diseases: these were claims which I decided, not without consideration, to challenge. I did so because I knew that both of these claims lack the support of science, whether our knowledge be derived from experiment or from experience.

But significant though this ill-informed effort to establish the claims of a particular bread is, the campaign of which it is a part is more significant still, and more serious in its consequences. Nominally undertaken in the interest of personal hygiene, it is actually inimical to this. Although not the motive of those medical men who support the campaign, a disastrous result of the latter is the creation in the public mind of the idea that health is an extremely difficult thing to secure. The citizen is led to believe, and to fear, that only by a series of close observances, and equally close restrictions, can he hope for physical salvation. So much so that many are saying: "It is high, I cannot attain unto it." The way of health is conceived of as a tightrope, along which we make a slow and trepidating progress. The least bias to this or to that side, not immediately corrected, or corrected too slowly or inaccurately, and we plunge headlong into the abyss. Here await us inflammations and ulcerations and cancer—especially cancer.

This is not my conception of the way of health, nor is it the experience of the ordinary healthy human being. Health is a broad and well-paved road; nature is both an excellent road-maker and an excellent road-mender. Not only does it require very little skill, and but a modicum of good fortune, to keep to it, the wayfaring man must be a fool indeed if he errs therein. Now and again there are bends which call for some care; there are cross roads; there is a goodly sprinkling of fools travelling; and pace carries risks of a special kind. But apart from these things the amount of negotiation needed is very little provided we keep control of the car.

Another idea has been promulgated of late, the idea which is embodied in the phrase "The Secrets of Good Health." This second conception is on all fours with the first and is equally regrettable. "Secrets," forsooth! As though good health were something masonic! Regard the carter driving his team, the sailor hauling on his rope, the smith working at his anvil; his physical fitness, far from being a mode of difficult and unnatural progression, or the result of initiation into a ritual, is the most spontaneous of all acquirements. There is here no "struggling, task'd morality," no "strife divine"; there is "no effort on his brow," he "does not strive," he "does not weep." Yet no health society inquires what bread he eats, if he gets sufficient vitamins, or how frequently waste products leave his body. Why should it? Such curiosity could no more discover the "secret" of health than could the question: "What porridge had John Keats?" lay bare the mystery of a poet's soul.

More than one critic has dubbed me the Mark Tapley of medicine. I prefer the rôle of Mark Tapley to that of Mrs. Gummidge. For I hold that in medicine society has a greater enemy than the man who kills joy, and that is the man who kills confidence.

There is yet another unfortunate aspect of this particular campaign. All pseudo-science is obstructive

to the progress of true science. The spread of irresponsible statements about the causes of cancer, such as the fiction that this disease is due to the eating of some special article of diet, tends to distract the public mind from the only way by which this great problem can ever be solved—namely, by painstaking and concentrated research. H. G. Wells, who has done more for the progress of scientific methods than any other man in his generation, puts this fact more eloquently than I can possibly do. "The disease of cancer," says Sempack in "Meanwhile," "will be banished from life by calm, unhurrying, persistent men and women, working, with every shiver of feeling controlled and suppressed, in hospitals and laboratories." Again, lamenting the paucity of workers in this field, he asks, "Where are the mighty armies of investigators? Nothing as yet but guerrilla bands that wander in the wilderness and happen upon this or that." No greater deterrent to an adequate appreciation of our present ignorance of the causes of cancer could possibly exist than the serving up to the public of private notions under the guise of established facts. And that certain medical men, who have in other fields earned a prestige which enables them to speak with authority, should endorse the fantastic vapourings of untrained laymen, is both pathetic and unfortunate.—I am, Sir, yours faithfully,

Harley-street, W., Sept. 28th, 1927. THOMAS HORDER.

LUMINAL IN EPILEPSY.

To the Editor of THE LANCET.

SIR,—I was much interested in the article by Dr. J. Tylor Fox in your issue of Sept. 17th. In a short paper which I published in your columns on August 5th, 1922 (p. 275), I reported my experience in the days of the early use of this drug. During the past five years I have continued the treatment of epilepsy with this drug in both hospital and private cases, and my experiences had led me to form similar views to those expressed by Dr. Fox.

In the majority of cases improvement has occurred in the first few months of treatment, but, unfortunately, observation of its use over a more prolonged period has not confirmed one's original opinion of its value. In many cases, after a period varying from 6 to 12 months, the frequency of the attacks tend to increase sometimes in an alarming manner, and this is often accompanied by a mental condition which can best be described as "mental cloudiness." When, for such reasons, the decision has been reached that the drug must be withdrawn, a difficult period is encountered, lasting from four to six weeks, even if the drug is withdrawn gradually. The patient is liable to develop a series of attacks which can almost be described as fulminating in character. This state has been more likely to occur in the case of children than in adults.

Accordingly, I have been gradually led to confine the use of luminal in epilepsy to certain selected cases, and to discontinue its use in the greater proportion of patients. The older drugs still remain the best agent in the treatment of epileptic seizures. I should mention that the drug I have used is luminal in suspension, in a bromide mixture, and not luminal-sodium. I am, Sir, yours faithfully,

Liverpool, Sept. 24th, 1927. W. JOHNSON.

"THE THOMAS SPLINT."

To the Editor of THE LANCET.

SIR,—I beg to thank you for the appreciative critique of my book on the "Thomas Splint" which appeared in your issue of August 13th (p. 337), and I shall be grateful if you will allow me a little space to reply to one or two points on which your reviewer and I do not seem to be in agreement. Your reviewer says:—

> In the description of the Thomas splint for the leg the lowest level of the ring is stated to be at the junction of the ring and inner upright. Surely the lowest point of the ring should be at the point where the tuber ischii comes in contact with the ring, so that naturally, with any displacement, this bony point of counter-extension will always tend to slip back and remain in contact with it."

I beg to assert that my statement is correct. In a properly made Thomas the lowest point of the ring is the point where it joins the internal bar, the word "lowest" being used to mean most inferior when the body is in the anatomical position or more simply nearest the foot and farthest from the head. If the point where the ring joins the internal bar be at a higher level than the point where the ring comes in contact with the tuber ischii the ring will press on the side of the perineum and adductor origins on the rami of pubis and ischium. These parts are not suitable for taking counter extension from. I do not use the splint in the Thomas manner in the initial treatment of fracture of the femur because I find the pull required to restore the limb to and retain it at its proper length causes at least some pain and discomfort to the patient from pressure on the tuber ischii, and these disadvantages do not occur when the splint is used in the Hodgen way.

Your reviewer is incorrect when he states that my method is no better than simple extension in a trough, because the essence of my method is not only to extend the leg to the same length as its fellow, but also to restore and maintain the arch of the femur, which is easily done by the pressure from below of the series of flannel bands passing between the side bars and secured by clips, and with the "key bandage" acting as the key stone does in a stone arch. The restoration of the arch of the femur is impossible or very difficult to achieve in any form of trough splint. Further, my 4-in. flannel bands and 4-in. sectional dressings allow free access to wounds, section by section, so that the restored arch is never lost. This is impossible to do in a trough splint. My method is unsuitable in the old and infirm because of the risk of congestion of the lungs from inclining the body so as to use its weight for the extending force. In these cases the probability of having to prop up the patient must be considered, and, therefore, the Thomas splint must be applied strictly in the Thomas manner, and if the patient be unable to stand sufficient pressure on the tuber ischii, it is better for him to put up with a little shortening rather than to lose his life from pulmonary complications.

I am, Sir, yours faithfully,

MEURICE SINCLAIR.

Harley-street, W., Sept. 24th, 1927.

CANCER AND ADRENALIN.

To the Editor of THE LANCET.

SIR,—On my return from abroad Dr. Cramer's letter in your issue on Sept. 3rd was brought to my notice. Dr. Stephens and I used adrenalin for the well-recognised purpose of localising another reagent. It was only incidentally that we noticed regression of tumours in control animals treated with local injections of adrenalin alone. We made no claim to priority.

On looking up Dr. Cramer's reference to his own experiment in 1905 I find that he injected a "toxic" dose of adrenalin into cancerous mice (number not stated) with the idea of causing hæmorrhage into the tumours. Only three mice survived and "in one the tumours had diminished in size by the fifth day. The animal was then killed." So that it does not appear that Dr. Cramer observed a single instance of complete regression. The two drawings of microscopic specimens he published are such as might be obtained from certain areas in many untreated tumours and are to my mind quite unconvincing. The whole reference consists of some 13 lines of print in a paper dealing with the action of radium on tumours and was unknown to me; but even if I had been aware of its existence I do not think I should have felt justified in referring to it since it does not appear germane to the subject under investigation.

Reicher investigated the effect of local injections of adrenalin fully and got results as good as, or better than, those obtained in the controls treated by Dr. Stephens and myself. In his paper in the *Deutsch. Med. Woch.*, 1910, he claims to be the first to have used adrenalin for the cure of tumours, and I have no reason to doubt the validity of his claim. He does not mention Dr. Cramer's name. Engel, in 1912, confirmed and extended Reicher's results. Dr. Stephens and I found that injections of adrenalin at a site remote from the tumour did not effect cure. If Dr. Cramer can obtain cures in this way, which as far as I know he has not yet shown, he may still, if he is anxious to do so, claim some priority, though he might have to dispute this, amongst others, with Opitz, Vorländer and Jung, who have published good results when using adrenalin, along with cholin, trypan blue, and cerium.

Dr. Cramer considers it "obvious" (always a word to use cautiously) that local injections as a means of treatment are of little importance. Here I entirely disagree with him. The essential point made in the paper by Dr. Stephens and myself, and, indeed, the whole trend of my recent work indicate that by appropriate local treatment an active immunity can be induced which is not local but *general*. This point Dr. Cramer appears not to have appreciated fully, for I can hardly imagine that he would underrate the value of any method which, by local treatment, can effect not only the disappearance of the local growth but leaves the animal immune, against subsequent inoculations of the same tumour, in every part of its body.—I am, Sir, yours faithfully,

THOMAS LUMSDEN.

Lister Institute of Preventive Medicine, London S.W., Sept. 23rd, 1927.

BREAST-FEEDING OF TRIPLETS.

To the Editor of THE LANCET.

SIR,—In these days when many medical men and not a few medical officers in charge of welfare clinics lightly advise artificial feeding, it is refreshing to find a mother of triplets nursing her infants.

Five months ago Mrs. W. gave birth to quadruplets, one of which died at the age of 3 days, the other three, Albert, Edward, and Betty, survived and are now healthy infants weighing 13 lb., 12 lb., 12 lb. 8 oz. respectively. There are two other children aged 11 and 7. The family lives in three rooms, rent of which is 11*s.* 6*d.* weekly, and the average wage of the father is £2 12*s.*

The mother is an ordinary working woman of the South London type, not very robust, and somewhat older than her years. The method of feeding the infants is a little unusual. All three are put to the same breast at one feed, and to the other breast at the next feed, but the first comer at one feed becomes the last at the next and vice versa; one infant is therefore always second comer, which may account for its slightly lower weight. Feeds are given at roughly three-hourly intervals.

The mother's diet is not excessive. In fact, she confessed that she would eat more were "her money better." She drinks, however, three pints of milk and a quart of water daily in addition to her ordinary three cups of tea and one cup of cocoa or coffee.

She has found out that she requires adequate rest, and this, with her extra fluid intake, has enabled her to suckle her infants without difficulty.

It is well known that many women are capable of nursing more than one infant, but even so it is a little surprising that this mother has escaped the ministrations of the many who consider that the nursing of one infant is beyond the power of the average mother.

I am, Sir, yours faithfully,

Lee-road, Blackheath, Sept. 26th, 1927. GUY NEELY.

ST. MARY'S HOSPITAL.—The board of management have extended the term of office of Dr. Graham Little, M.P., as physician in charge of the Dermatological Department for a further period of five years as from Oct. 25th, 1927.

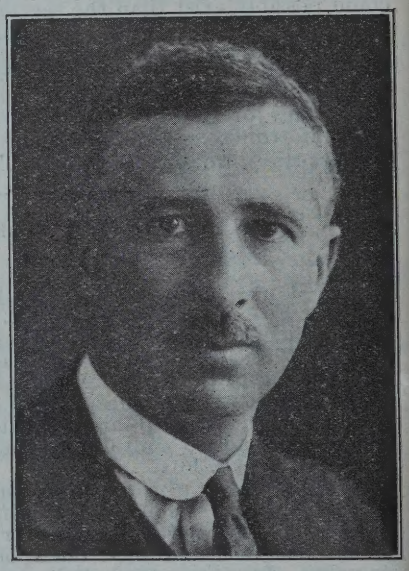
RADCLIFFE INFIRMARY, OXFORD.—In connexion with a post-graduate course at this hospital, Dr. J. Gravesen, medical superintendent of Vejlefjord Sanatorium, Denmark, will give an illustrated lecture on the Modern Treatment of Pulmonary Tuberculosis, at 3 P.M. on Friday, Oct. 14th

Obituary.

ADRIAN STOKES, D.S.O., M.D. DUB., M.R.C.P. LOND., F.R.C.S. IREL.

WE have to record the death of Dr. Adrian Stokes, Sir William Dunn Professor of Pathology at Guy's Hospital, which occurred at Lagos on Sept. 19th. Early this year he was asked by the Rockefeller Commission to go to West Africa to investigate the transmission of yellow fever, which he had previously studied on the Gold Coast. His death was due to infection by this disease. The following account of his life and work has been written by one of his colleagues.

It is impossible to estimate the loss which medical science and education have sustained by the death, at the early age of 41, of Prof. Adrian Stokes. Valuable and varied though they were, his published contributions afford no real index of his genius and of his remarkable power of inspiring clear thinking, hard work, and the best kind of scientific enthusiasm in others. Colleagues and students—and his colleagues, young and old, were among his students and always appealing to him for advice—all held him in the highest affection and esteem. He was a most open-hearted, generous, and lovable man. Save only to those whom he judged to be insincere he set no barriers in his life or his laboratory. All others were welcome and sure of his friendship and coöperation. Seldom have the love of scientific truth and a warm humanity been more closely welded in the same personality.



PROF. ADRIAN STOKES.

(Photograph by Elliott and Fry, Ltd.)

The war gave Adrian Stokes his great opportunity. He joined the R.A.M.C. on the declaration of hostilities and went to France on August 11th, 1914. From that day onward he expended himself in every conceivable way in furthering and improving the work of his own branch of the service. No matter what the task nor whether it were really his concern, provided only that it might save or help to save a single life, he would strive to ensure, and generally in person, that it was done. The incidents which helped to make him something of a legend among his friends and associates are too numerous to record, but it will not be forgotten how in September, 1914, he rode 140 miles on a shaky motor-cycle to bring a supply of tetanus antitoxin to where it was sorely needed. When typhoid fever appeared in the Guards' Brigade in those early months it was Stokes who anticipated the whole idea of the mobile laboratory by equipping his motor-cycle and sidecar (his "yoke," as he called it) with an incubator and a sergeant of the R.A.M.C., and going forth to capture (as he successfully did) the "carrier" responsible for the epidemic. He was the first in France to isolate from the blood stream the organism of gas gangrene,

although his account, through some editorial error, was held back from publication for 18 months. Early in 1915 we find him acting as the mainspring and unofficial liaison officer to the mass of bacteriological and hygienic work necessitated by a grave epidemic of typhoid fever among the Belgian refugees in the neighbourhood of Ypres. This epidemic never extended to the troops which crowded all the billets there. In the same year he was occupied with an outbreak of cerebro-spinal fever in the northern British armies, busy with the work of diagnosis, examination of carriers and contacts, and at the same time treating and instructing medical officers in the treatment of the cases with appropriate sera.

We next find him in charge of a mobile laboratory stationed for two years near Poperinghe, attached for messing purposes to No. 10 Casualty Clearing Station, and devoting every moment of his arduous days not merely to his own routine duties, but also to the bigger task of helping and inspiring others. Surgeons, physicians, and administrative staff were constantly in his debt, and yet all his work was done unobtrusively and he never sought and often failed to gain the credit for important innovations due to him. He was, in a sense, the conscience of all the medical units in his zone. Should the word go forth or his own observations suggest that this or that new method of treating wounds or shock should be put in force, it was Stokes, with his friendly, unorthodox methods of approach, who prompted the surgeons and saw, by personal contact, that the work was properly done. When it was found that warm ether anæsthesia lessened shock and saved lives, and the authorities could only allow a ration of one apparatus per C.C.S., he at once improvised, with his own hands, as many outfits as were needed. When a certain C.C.S. was flooded one morning with the victims of a bad phosgene gas attack, and oxygen supplies were short while the old method of administration with a funnel was shown to be futile, it was he who conceived the simple idea of feeding oxygen continuously to the men (four being supplied from one cylinder) through nasal catheters. The method became universal along the front, was far more efficacious than the more elaborate apparatus supplied later, has been extended to civilian practice ever since, and must have saved countless lives. All these and kindred actions were wholly spontaneous and quite outside his official sphere as bacteriologist, and yet he was never behind-hand with his very arduous laboratory tasks. In times of stress he would become anæsthetist or surgeon, but even then would often start his day early with post-mortem examinations, undertaken in the hope that they might provide useful information in relation to the effects of wounds or gas or disease. Sometimes his quick humanity would outbid his zest for scientific accuracy. Although such incidents were few, more than one war widow whose husband was found dead by the wayside on a bitter winter's night, having obtained unauthorised access to the rum jar, draws a pension to-day because a kindly pathologist found evidence of nephritis acquired "in the field" and reported "death from uræmia."

He did, again, much good work on trench nephritis dysentery, and wound infections, but his most brilliant piece of research was in connexion with an epidemic of spirochætal jaundice (spirochætosis icterohæmorrhagica), which appeared in the salient in 1916. He was the first to recognise cases clinically, and then pursued the inquiry with animal experiments and proved the disease to be identical with that first described in 1914, but more fully in March, 1916, by Japanese investigators. He showed that the rats infesting the trenches were the carriers of the spirochæte and with the aid of "spot-maps" helped to discover what parts of the trench system were responsible for the majority of the cases. This disease is clinically and in its morbid anatomy almost identical with yellow fever, if less lethal, and it was undoubtedly Stokes's work in Flanders which led to the invitation to join the Rockefeller Commissions on Yellow Fever dispatched to West Africa soon after the war and again recently. For his war services he was awarded the D.S.O., the O.B.E., and the Belgian Order of the Crown, and was several times mentioned in dispatches. Stokes went to Germany with the Army of Occupation, came through a severe illness there, and devoted his energies particularly to the big problem of venereal infection among the troops.

After demobilisation Stokes returned to his old school at Trinity College, Dublin, where he became Professor of Bacteriology. In 1922 he was asked to enter for the Chair of Pathology—the Sir William Dunn Professorship—then vacant at Guy's Hospital, and was selected from a very strong list of applicants. He quickly established himself in his new surroundings and won the friendship and eager support of his colleagues. For the students pathology was at once endowed with a new popularity and his classes were always crowded. His phraseology, always unorthodox and quaint, added to the attractiveness of his essentially practical lectures and demonstrations. For his friends, senior and junior, 4 o'clock tea in "Stokes's Lab." became quite an institution. However trivial the requests that came to him at his bench he always left what he was doing to interest himself in the problems of others. If he published but little in his later years it was partly because his time was so fully occupied and he conceived teaching to be his first function, partly because he would never publish anything incomplete, and partly because he would insist on the credit for work done in collaboration falling to the collaborator. To students with personal problems, in sickness or in sorrow, he offered, from time to time, not only his open-handed friendship and holiday companionship, but his very roof.

Of the progress of his researches at Lagos nothing official is known as yet, but from certain vivid and cheerful letters to friends it seems reasonable to suppose that things were going well, and that some of his transmission experiments had already given gratifying results. Until further news is received it can only be surmised that he became accidentally infected by one of his own mosquitoes. Death followed within a few days of the first symptoms.

The son of Henry John Stokes, an Indian Civil Servant, and grandson of the famous William Stokes, he carried on wonderfully a great family tradition. He had a brilliant career as a student. Outside his work he was a keen fisherman and a fearless yachtsman, a good cricketer, and a member of the M.C.C. He was bluff and humorous, intolerant of fools, and could be stirred to a white heat of indignation by any base action or hint of injustice. He loved Ireland and was clearly, although he never spoke on the subject, deeply injured by the circumstances and consequences of the rebellion. As has been shown, he was completely unselfish, and no man was ever more loyal to his friends and to his duty.

When, lamenting the early end to his career, we are prompted to exclaim against the waste of so valuable a life. Should we not rather pause in pride and remember that he accomplished more for his fellow-men and for the medical sciences—taking only the period from August, 1914, to his death from yellow fever in September, 1927—than most men can ever hope to accomplish in a long life-time? J. A. R.

Our Dublin correspondent writes: The death of Prof. Stokes has been felt not only as a great loss to medical science, but as a personal grief by many of the profession in Ireland. Although he spent the last five years of his life as a teacher in London, the whole of his previous career was associated with Dublin. Sprung from a family famous in medicine as well as in art and scholarship, Adrian Stokes was the grandson of William Stokes, the most famous of Irish physicians. He received his medical education at Trinity College, Dublin. His zeal for research and his scrupulous accuracy attracted the attention of his teachers, and particularly of the late Alexander Charles O'Sullivan, at that time lecturer in pathology

in Trinity College. Shortly after obtaining his medical degrees he was appointed an assistant in O'Sullivan's laboratory, where he continued to work until the war called him to other duties. In 1919 he returned to Dublin, where his colleagues hoped that he might spend a long life in adding to knowledge by his researches, and stimulating those around him by his spirit. But the period was not a hopeful one in Ireland, and no one was much surprised when, in 1922, Stokes accepted an unsought and unexpected invitation to a wider sphere of activity in London. Though Stokes thus left us we always regarded him as one of ourselves and counted his reputation among the trophies of the Dublin School of Medicine. His death brings to all who knew him well a sense of surprise as well as of personal bereavement. He was so full of vitality that one never thought of losing him by death. Intellectually a giant, in personality he retained many of the characteristics of a child. He had a child-like simplicity, a child-like honesty, and above all a child-like kindness. And he was subject, too, to the same instinctive dislikes as a child and had something of the same brusqueness in expressing them. As a class teacher he was excelled by many lesser men. He had not the faculty for putting himself in the place of the beginner, and he often over-estimated the knowledge and intelligence of his hearers. But in the laboratory it was different. No pains were too much, no help too great for him to give. He was always busy, but no pressure of work prevented his spending himself in the interest of all honest inquiries after knowledge.

Medical News.

MEDICAL DEFENCE UNION.—The annual general meeting was held at Harrogate on Sept. 24th. Sir Herbert Waterhouse, the President, who took the chair, said that the annual report for 1926–27 was a record of continued growth and progress. The Hume-Spry case had been the biggest and the most anxious case with which the Union had been concerned during the year, and had, he thought, cost more than any other action since the Union was founded. Fortunately, the members had been completely vindicated. He must, he said, "protest against the existing judicial system which permits medical practitioners, who have done their duty honestly in the interests of the public and of the patient, to be subjected to a lengthy and costly trial, because the plaintiff is able to produce affidavits from medical men who see him some months or even years after he was certified, testifying—without any inquiry of those in professional attendance on the patient at the time of, or prior to, certification—that he was not insane when certified, and that those who certified acted negligently, and/or in bad faith." Except for such affidavits the Hume-Spry case would never have gone to trial. The verdict of the jury and the remarks of the judge sufficiently indicated the value they attached to such evidence. The fact that evidence of this type was repeatedly given in court made him wonder whether the disciplinary powers of the profession did not require strengthening. The history of the Hume-Spry case was certainly a striking illustration of the benefit of membership of the Union.

In numerous other cases, continued the President, the Union had been able successfully to defend members whose professional work had been called in question, and although in some few cases they had been compelled to effect a settlement out of court by a monetary payment, he was glad to say that no single verdict had been recorded against a member of the Union. The finances were so satisfactory that it had been possible to increase still further the benefits of membership. The Council was now prepared to defend an action brought against a member in consequence of the acts or omissions in any event of a subordinate medical officer or a non-medical subordinate, and of a partner or assistant if he belonged to either of the two English Defence Societies. Also a member could now obtain protection against actions arising out of the acts or omissions of an assistant who was not himself a member of any defence society, by paying an additional annual subscription of 10s. in advance. The reciprocal arrangement with the other society as regards assistants had now been extended to partners. He must again emphasise the absolute necessity for everyone engaged in active practice to belong to the Medical Defence Union. The Union could only defend its own members, and they must be in benefit.

Referring to a circular letter issued last February to every member of the Union on the subject of X ray examinations in cases of injury to bones or joints, the President remarked that it had evidently been very much misunderstood. It had been interpreted by some as implying that a member who had not made an X ray examination in any such case would not be defended. That was not what the letter said, nor what the Council intended. It was a warning to members that in all such cases the member should in his own interests advise an X ray examination, and that when such advice was not followed, the member should for his own protection place the advice given on record by writing a letter to the patient and keeping a copy in case of future trouble. This advice was based on experience of scores of cases, but was constantly ignored, thus depriving the Council of the only evidence which as a rule made a successful defence possible. The President concluded by expressing sincere thanks to Dr. James Neal, the general secretary, and to Mr. Hempson, the solicitor, for valued help and guidance. He was certain that no society had two important officials more reliable and capable.

The report of the Council and the financial statement for the year 1926 were adopted unanimously. Dr. E. C. Greenwood, Dr. H. Robinson, and Mr. W. G. Spencer, the retiring members of Council, were re-elected. The auditor, Mr. Lewis Hardy, F.C.A., was reappointed, and authority was given for the payment of the first-class railway fares (with expenses if detained for the night) of members of the Council attending council meetings from provincial centres.

The President referred to certain objections[1] raised by the Todmorden Medical Society to a circular letter issued by the Council on Feb. 15th, 1927, to members of the Union only, on the subject of X ray examinations, and explained that the Council had invited any members of the Todmorden Medical Society who were also members of the Medical Defence Union, to attend the annual meeting and state their views. No member of the Todmorden Medical Society was present, and after some discussion a resolution approving the circular letter issued by the Council was unanimously passed, members of Council who were present abstaining from voting at the request of the President.

A hearty vote of thanks to the President and Council for their services during the past year was passed with acclamation.

MEDICAL SOCIETY OF LONDON.—The annual general meeting will be held on Monday, Oct. 10th, at 8 P.M., after which Mr. H. W. Carson will give a presidential address on Surgery in the Early Days of the Society. Other forthcoming arrangements include a discussion on the Duodenal Tube, at 8.30 P.M., on Oct. 24th (introduced by Dr. B. B. Vincent Lyon), and a clinical evening at 8 P.M., on Nov. 14th.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—From Oct. 3rd to 15th, from 10 A.M. to 4 P.M. daily, there will be a course at the National Hospital for Diseases of the Heart (entry limited to 20). The Central London Throat, Nose and Ear Hospital holds it usual October course from the 3rd to the 22nd. It consists of (1) a clinical course, occupying most of each day, which may be taken alone if desired, (2) an operative surgery class from 10 to 11.30 A.M. daily, (3) a practical course in peroral endoscopy, and (4) a course in pathology and bacteriology suitable for D.L.O. students. The numbers for the three last courses are limited. On Oct. 4th the London School of Hygiene and Tropical Medicine will start a series of clinical demonstrations, to be given on Tuesdays and Thursdays at 2 P.M. until Oct. 28th. At 5 P.M. on Fridays, from Oct. 7th to 28th (inclusive), a course in Antenatal Diagnosis and Treatment will be given by Prof. Louise McIlroy at the Royal Free Hospital (entry limited to 10). The subjects of other courses are: Diseases of Children at the Paddington Green and Victoria Hospital for Children, from Oct. 17th to 29th; Gynæcology, at the Chelsea Hospital, Oct. 17th to 28th; Electrotherapy, at the Royal Free Hospital, Oct. 12th to Nov. 2nd; and Ophthalmology, at the Royal Eye Hospital, Oct. 24th to Nov. 5th. On Oct. 3rd a two months' course in neurology will begin at the National Hospital, Queen-square. November courses include two late afternoon courses for practitioners, and courses in Diseases of Children, Diseases of the Chest, Neurology, Proctology, Urology, and Venereal Diseases. A series of lectures, entitled Practical Hints on Medicine, Surgery, and the Applied Specialties, is to be given on Mondays, at 5 P.M., in the Lecture Room of the Medical Society, Chandos-street, W. 1, beginning on Oct. 17th. Series of demonstrations will start during the same week. Both lectures and demonstrations will be open to members of the medical profession without fee. Copies of syllabuses are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1. They will be sent regularly on publication if desired.

[1] THE LANCET, 1927, i., 1108 and 1153.

ROYAL INSTITUTE OF PUBLIC HEALTH.—It is reported that the Council of the Institute has decided to bestow the Harben Gold Medal for 1928 upon Sir Ronald Ross, F.R.S., director-in-chief of the Ross Institute and Hospital for Tropical Diseases.

CHARING CROSS HOSPITAL MEDICAL SCHOOL.—The Huxley lecture will be delivered by Sir Archibald Garrod, F.R.S., Regius Professor of Medicine in the University of Oxford, on Thursday, Nov. 24th. The subject will be Diathesis.

LIVERPOOL PSYCHOLOGICAL SOCIETY.—Dr. Barton Hall will deliver a presidential address to this society on Dreams and Dreaming, at the University of Liverpool, on Oct. 4th. Details of the society's programme may be had from the secretary at the University.

A SISTER'S EFFORTS FOR WESTMINSTER HOSPITAL. A sister at Westminster Hospital has by her own efforts collected the sum of £600 for the perpetual endowment of a children's cot in the hospital.

INVALID CHILDREN'S AID SOCIETY.—The new Hospital and Home of Recovery for Heart Cases (Children) at West Wickham, Kent, will be opened on Thursday, Oct. 6th, at 3 P.M., by Lady Lennard.

ST. MARY'S HOSPITALS, MANCHESTER.—During the year 3269 patients were treated by the maternity department—1489 in their homes and 1780 in the wards. The mortality-rate for all admissions is 2·3 per cent.

A HOSPITAL FOR CANVEY ISLAND.—A committee has been formed to raise funds for a hospital for Canvey Island. An excellent piece of land has been offered as a site on the main road near the recreation ground, with a further space at the rear for any future extensions.

SCUNTHORPE WAR MEMORIAL HOSPITAL.—A second gift of £5000 has been received by Scunthorpe War Memorial Hospital from Mr. Stephen Cliff, of Leeds. The foundation-stone of the hospital will be laid on Oct. 13th by Lord Buckland, and the institution when completed will have 112 beds and will have cost over £100,000.

ST. ANDREW'S HOSPITAL, NORTHAMPTON.—A new reception hospital at St. Andrew's Hospital for Mental Diseases will be opened by Viscount Cave, the Lord Chancellor, at 3 P.M. on Friday, Oct. 14th. At the ceremony Sir Frederick Willis, Chairman of the Board of Control, will make an initial statement.

FAMILY ENDOWMENT SOCIETY.—A public conference has been arranged by this society to be held on the evening of Friday, Oct. 14th, and the afternoon and evening of Oct. 15th at the London School of Economics, Houghton-street, W.C. Sir William Beveridge will give an address on the case for Family Allowances; whilst the other speakers will include Mr. R. A. Fisher, D.Sc., Mr. H. N. Brailsford, Principal John Murray, and Mr. J. L. Cohen. Prof. V. H. Mottram will speak on the Physiological Basis of the Minimum Wage. Particulars may be had from the hon. secretary of the society at 24, Tufton-street, London, S.W. 1.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
TUESDAY, Oct. 4th.—5.30 P.M. (Cases at 4.30 P.M.) ORTHOPÆDICS. Presidential Address: Mr. W. Rowley Bristow: Arthrodesis, to be followed by a discussion. Relevant cases only will be shown.
WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. Paper: Dr. Kenneth J. Franklin: Valves in Veins—an Historical Survey.

LECTURES, ADDRESSES, DEMONSTRATIONS &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Oct. 3rd, to SATURDAY, Oct. 8th.—NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland-street, W. Special post-graduate course in Cardiology, occupying all day from 10 A.M. to 4 P.M.—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C. Special course in Laryngology, Rhinology, and Otology, including Operative Surgery, a practical course in Peroral Endoscopy, and a course in Pathology and Bacteriology suitable for D.L.O. Students. All day.—LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Endsleigh-gardens. Tues. and Sat., clinical demonstration on Diseases in the Tropics.—NATIONAL HOSPITAL, Queen-square, W.C. Special two months' course in Neurology.—ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—On Fri., at 5 P.M., demonstration on Antenatal Diagnosis and Treatment. Further information from the Secretary, Mayfair 2236.

WEST LONDON HOSPITAL, POST-GRADUATE COLLEGE, Hammersmith, W.
MONDAY, Oct. 3rd.—11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Donald Armour: Operations. 4.30 P.M., Sir H. Simson: Post-Graduate Education in Obstetrics.
TUESDAY.—10 A.M., Medical Registrar: Ward Demonstration. 2 P.M., Mr. Sinclair: Surgical Out-patients. 3 P.M., Dr. Pritchard: Medical Wards.
WEDNESDAY.—10 A.M., Dr. Owen: Medical Diseases of Children. 2 P.M., Mr. Gibb: Eye Department.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Dr. Ironside: Medical Out-patients. 3 P.M., Mr. Simmonds: Surgical Out-patients.
FRIDAY.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Mr. Addison: Operations. 4.30 P.M., Mr. Vlasto: Mastoiditis (Lecture).
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy and Ward List. 10 A.M., Dr. Owen: Medical Diseases of Children.
Operations, Medical, Surgical, and Special Out-patients, daily 10 A.M. to 5 P.M.; Saturdays, 10 A.M. to 1 P.M.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Oct. 3rd.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.
WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.
There will also be a special demonstration of medical cases on Monday, Oct. 3rd, at 2 P.M. and of X ray cases on Wednesday, Oct. 5th, at 2.30 P.M. by Dr. Whiting and Dr. Shanks respectively.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Oct. 4th.—5 P.M., Dr. J. H. Stowers: Introductory.
THURSDAY.—5 P.M., Dr. J. M. H. MacLeod: Anatomy of the Skin.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Oct. 4th.—4.15 P.M., Mr. W. H. Hey: The Past Year's Advances in Surgery.
FRIDAY.—Dr. E. M. Brockbank: Dr. John Ferriar (1761–1815); Public Health Affairs.

Appointments.

Queen Charlotte's Maternity Hospital: TREE, J. R., M.R.C.S., L.R.C.P. Lond., Senior Resident Medical Officer; PEIRCE, G. E. G., M.R.C.S., L.R.C.P. Lond., Assistant Resident Medical Officer; WILLIAMS, J. C., M.R.C.S., L.R.C.P. Lond., District Resident Medical Officer.

Vacancies.

For further information refer to the advertisement columns.

Ascot, Heatherwood Hospital.—Res. Asst. M.O. £300.
Belgrave Hospital for Children, Clapham-road, S.W.—H.P., Asst. H.P., and H.S. Each at rate of £100.
Bradford Royal Infirmary.—Two H.S.'s and H.P. Each £150.
Bury Infirmary.—Third H.S. At rate of £150.
Carshalton, Surrey, Queen Mary's Hospital for Children.—Jun. Asst. M.O. £500.
Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Hon. Asst. Out-patient. Reg.
Dumfries, Crichton Royal Mental Hospital.—Asst. Phys. £350.
Dundee Royal Infirmary.—Asst. S.
Durham County Council, &c.—Dist. Tub. M.O., &c. £500.
Exeter, Royal Devon and Exeter Hospital.—H.P. Also Cas. O. At rate of £130 and £100 respectively.
Gloucestershire Royal Infirmary, &c., Gloucester.—Res. Surg. O. and Asst. H.S. At rate of £175 and £120 respectively.
Grosvenor Hospital for Women, Vincent-square, S.W.—Hon. Anæsthetist.
Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—Cas. M.O., H.P. Also H.S. Each at rate of £100.
Hendon Union, Redhill Hospital, Edgware.—Res. Deputy Med. Supt. £300.
Hospital for Consumption and Dis. of Chest, Brompton, S.W.—H.P. £50 for six months.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—Hon. Anæsthetist. Also Res. M.O. and H.P. At rate of £150 and £100 respectively, and Med. Reg. £100.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S., H.P., and Asst. Cas. O. Each £50.
Hospital of St. John and St. Elizabeth, 40, Grove-End-road, N.W. Res. H.S. At rate of £75.
Hove Hospital, Sackville-road.—Res. M.O. £150.
Jersey General Hospital and Poor-Law Infirmary.—Res. M.O. £200.
Leeds, City Sanatorium, Gateforth.—Res. M.O. £400.
Liverpool Royal Children's Hospital, Myrtle-street.—Res. Cas. O. £120.
London Hospital, E.—Asst. P. Also 1st Asst. and Reg. to one of the Med. Firms, and 1st Asst. and Reg. to one of the five Surg. Firms. Each £300.
London Temperance Hospital, Hampstead-road, N.W.—Clin. Asst., Ear, Nose and Throat Dept.
Manchester Maternity and Child Welfare Centres.—Infant Clinic M.O. £600.
Manchester Royal Infirmary.—Jun. Anæsthetist. £125.
Middlesex Hospital Medical School, London, W.—2nd Demonstrator for the Dept. of Physiology.
Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Hon. S. to Ear, Nose, and Throat Dept.
Miller General Hospital for South-East London, Greenwich-road, S.E.—Out-patient O. £150.
North Middlesex Hospital, Edmonton, N.—Res. M.O. £200.
Norwich, Norfolk and Norwich Hospital.—H.P. and H.S. Each £120.
Oswestry, Shropshire Orthopædic Hospital, &c.—Two H.S.'s. Each £200.
Ovamboland, South-West Africa.—Dist. S. £1000.
Paddington Green Children's Hospital, London, W.—H.P. At rate of £150.
Princess Louise Kensington Hospital for Children, N. Kensington. H.P. and H.S. At the rate of £100 and £75 respectively.
Queen's Hospital for Children, Hackney-road, E.—H.S. At rate of £100.
Rochdale Infirmary and Dispensary.—Jun. H.S. £200.
Rotherham Hospital.—H.P. £180.
Royal Free Hospital, Gray's Inn-road, W.C.—Cas. O. At rate of £150. Obstet. and Gynæcological Unit, Sen. Asst. part-time. £350. Second Asst. £500. Third Asst. £270. Also Res. Asst. Pathologist. £150.
Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Five Registrars. Each £100.
Royal Northern Hospital, Holloway, N.—Med. Reg. £100.
St. Mark's Hospital for Cancer, City-road, E.C.—Radiologist. Also H.S. At rate of £75.
St. Paul's Hospital for Diseases of the Genito-Urinary Organs, &c., Endell-street, Holborn, W.C.—Hon. Clin. Asst.
Seamen's Hospital, Albert Dock, Connaught-road, E.—Ophthalmologist.
Sheffield Royal Hospital.—Hon. Asst. P.
South London Hospital for Women, Clapham Common, S.W.—Clin. Asst. £1 1s. per attendance.
Sudan Government, Wellcome Tropical Research Laboratories, Khartoum.—Asst. Bacteriologist. £E.720.
Tunbridge Wells Eye and Ear Hospital.—H.S. £150.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Hon. Med. Reg. and Hon. Surg. Reg. Also Hon. Out-patient Anæsthetist. 10*s.* 6*d.* per attendance.
Warwick County Mental Hospital, Hatton.—Asst. M.O. £300.
Warwickshire and Coventry Joint Committee for Tuberculosis.—Asst. Tuberculosis O. £650.
West Sussex County Council and Bognor Urban D.C.—Asst. County and Dist. M.O.H. £700.

Vacant appointments for Certifying Factory Surgeons are announced at Kenninghall (Norfolk) and at Ellon (Aberdeenshire).

Births, Marriages, and Deaths.

BIRTHS.

COOKSEY.—On Sept. 23rd, at a nursing home, Worthing, Sussex, the wife of Wm. O. Cooksey, L.D.S.R.C.S. Eng., of a daughter.
FISCHER.—On Sept. 21st, at King's Langley, the wife of Dr. Reginald Fischer, of a daughter.

MARRIAGES.

LLOYD—SOLOMON.—On Sept. 15th, at Swansea, William Ernest Lloyd, M.D., M.R.C.P., to Irene Olive Neville Solomon.

DEATHS.

CHIPPERFIELD.—On Sept. 23rd, at Epsom, Thomas John Burgoyne Pearse Chipperfield, M.R.C.S., L.R.C.P., in his 72nd year.
COLEMAN.—On Sept. 22nd, at Leicester, Denis Joseph Coleman, M.B., aged 31.
JOULE.—On Sept. 19th, 1927, at Claremont, Rose Hill, Dorking, John Samuel Joule, M.D. Lond., late of Pinner, Middlesex, formerly of Paddington, aged 77 years.
LANKESTER.—On Sept. 19th (suddenly), at Eastbourne, Ralph A. R. Lankester, M.D., of Bradford, Yorks.
O'KELLY.—On Sept. 25th, at The Acland Home, Oxford, Thomas O'Kelly, M.D., late of Chipping Norton, aged 70 years.
STOKES.—On Sept. 19th, at Lagos, West Africa, Prof. Adrian Stokes, M.D., D.S.O., O.B.E., in his 41st year.
WALLACE.—On Sept. 24th, at New Romney, Kent, John Jamieson Wallace, M.D.

*N.B.—A fee of 7*s.* 6*d.* is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Comments, and Abstracts.

CLEAN MILK.*

BY FREDERICK T. G. HOBDAY, C.M.G., F.R.C.V.S., F.R.S. EDIN.,
PRINCIPAL OF THE ROYAL VETERINARY COLLEGE OF LONDON.

IT seems an anomaly in this twentieth century, when so much is being done in the domain of hygiene, to speak of anything which is sold for human consumption as "clean." The anomaly is all the greater since it only needs complete understanding and determined collaboration between the medical and veterinary professions to ensure that milk shall always be clean and never anything else.

Method, not Equipment.

In going about the country I have found that the public is not only very ignorant of the dangers of drinking contaminated milk but is also very apathetic; whilst the condition of many of our dairies and cowsheds and the way in which milk is obtained from the cow can only be described as absolutely filthy. One does not expect to find cows in palaces, but one does expect that they shall be kept healthy and reasonably clean. The statement has been made over and over again that the cost of producing *clean* milk is prohibitive to the average farmer, but that this is not so is evident from the results obtained in districts where capable organisers and enthusiastic members of agricultural and dairying committees have taken the matter in hand.

In a recent number of the *Veterinary Journal* Mr. W. A. Hoy, of the National Institute for Research in Dairying, gives briefly the following rules to be observed in producing milk: 1. The long hair on and around the udder is to be kept clipped to make cleaning easier and to avoid the accumulation of dirt. 2. Before each milking the udder and its immediate surroundings are washed clean. 3. The milker's hands are washed between the milking of each cow. A clean milking suit is worn and a scrubbed stool is used. 4. The first milk from each quarter is rejected and the milk taken into a sterilised small-topped covered milking pail. 5. The milk is strained and cooled immediately. 6. After milking, all utensils are washed clean and then sterilised by steam. This is a very important factor in influencing the bacteriological count of the milk.

As is pointed out by Mr. Steele Bodger, in the May issue of the same journal, "it is impossible to emphasise too strongly that it is *method* and not *equipment* which is the all-important factor in the production of clean milk. . . . It is the 101 little things which are so important."

All the rules given above are easy to follow and none is impossible even to the poorest aspirant to dairy farming; but the following extract from a letter recently sent to me by a veterinary surgeon in Lincolnshire shows how far they are neglected, and emphasises the necessity for educational propaganda on these lines: "In this part of Lincs. the ordinary dairyman and farmer has no idea of hygiene and cleanliness; 95 per cent. are wet milkers. They begin by milking a little on to their hands (which in the majority of cases are dirty), then milk into the pail; when their hands and fingers become sticky they dip them into the milk. Just imagine a cow with short teats and a milker with dirty hands. I rarely drink cow's milk and prefer goat's milk—and milk the goat myself."

It would be invidious, perhaps, to mention any one district as being in advance of another, but the propaganda and practical pioneer work done by the National Institute for Research in Dairying (University of Reading), under Dr. Stenhouse Williams and his band of scientific workers, certainly does stand out for what it has done amongst the dairy farms of Berkshire. According to Mr. Hoy, about one-sixth of the milk-supply of Reading (which is a town of 100,000 inhabitants) is Grade A (tuberculin tested), and it is interesting to note that no other graded milk, raw or pasteurised, is sold in the town. Sixty per cent. is bought by private consumers, of whom half belong to the working classes, and the remaining 40 per cent. is taken by hospitals and other institutions. The retail price in the summer is 3½*d.* per pint and in the winter 4*d.*, as compared with 3*d.* and 3½*d.* for ordinary milk. What has been done in Berkshire can be done by other counties. Only yesterday, in Somersetshire, I had the opportunity of seeing a dairy herd of 70 cows supplying Grade A (tuberculin tested) milk from a collection of ancient

* Being the substance of an address delivered before a joint meeting of the Guildford Branch of the British Medical Association and the Royal and Southern Counties Branches of the National Veterinary Association.

buildings which had been completely modernised and brought up to date a few years ago when building was dear, at an expenditure of less than £900—the major part of which was spent upon the impervious transformation of the flooring and walls. This expenditure has already repaid its owner several times over.

Tuberculosis.

Lieut.-Colonel F. E. Fremantle has summed up the requirements of the public health in respect of the milk-supply as follows: "The problem then is to provide at the house door a cheap and plentiful supply of clean milk, free from the germs of tuberculosis. It concerns the health both of man and of animals, and the Ministries, therefore, of Health and of Agriculture. At the farm it involves care in the health, management, and breeding of the cattle; attention to buildings, equipment and water-supply, to the milkers and their methods, to proper treatment of the milk and proper supervision throughout. In transit it depends on speed, protection, and coolness. . . . At its destination the chief need is for proper storage of the milk." In that paragraph we have in a nutshell the principles which underlie a supply of clean milk to the general public, and it illustrates admirably the need for collaboration between the medical and veterinary professions. Milk needs attention in its whole passage from the cow to the consumer. In the cow itself there are questions of health and cleanliness. The statement is made again and again that there are practically a million cows suffering from tuberculosis in Great Britain, and although only a comparatively small proportion of these have tuberculosis of the udder, it is admitted that the question of eradication is not only one of cost but one of expediency.

The United States are waging war on tuberculosis on a large scale under what is known as the "accredited herd" and "area eradication" plans. It is estimated that in the States there are already 13 million cattle which are free from tuberculosis, and the districts in which they are kept are so hemmed in with strict regulations and veterinary supervision that it is difficult, if not impossible, to reintroduce amongst them cattle which are not certified as free from this disease. What has been done in America can be done in Great Britain, and when once tuberculosis has been stamped out, our insular position ought to make it comparatively easy to keep our herds free.

That the new Bovine Tuberculosis Order (1925) is not perfect has recently been brought to the notice of the medical and veterinary professions by Dr. William Savage.[1] The Order throws the onus of diagnosing and reporting a suspected case of tuberculosis on the owner, but the owner has not sufficient knowledge to make the diagnosis until his animal has become diseased in an advanced stage, and by that time it has probably infected others. The deadly work has thus been done before the veterinary inspector sees the herd, and the obvious remedy is that cattle should all be periodically and regularly inspected by qualified veterinary experts. As Dr. Savage says, "It should be made a duty under the Order to report all animals *suspected* to belong to one of the designated groups. . . . The local authority should provide veterinary assistance, free of charge, to ascertain if these suspected animals did come under the Order. As a natural corollary any owner found to have an animal in the advanced stage of tuberculosis which he should have reported (and did not) as a suspected animal, would be fined and no compensation paid for slaughter. This would increase his interest in the problem. The benefit of free veterinary assistance for suspected animals would be of great assistance to owners of herds, and only the neglectful, indifferent farmer would be penalised. It would prevent some of the scandals which occur at present of cows being deliberately milked to the bitter end, although clearly in an advanced stage of tuberculosis, and then when no longer of any use as milkers being reported and compensation claimed."

Inspection.

To put the inspection of milk from the cow to the consumer on a satisfactory basis, the inspection board, to be complete, should have a medical officer of health, a veterinary officer of health, and a sanitary inspector. Each would find plenty to do in his own legitimate sphere and neither would overlap the other in the performance of his duties. At the present time in England it is not an exaggeration to say that there are many hundreds of milking sheds in which the inspector appointed by the Ministry of Health, usually a medical man, has never set foot, and it is not far from the truth, too, to say that the official inspector, even if he tries to perform his duties properly, often has no practical knowledge of what he is supposed to inspect. The inspection of the living animal is obviously the job of the veterinarian, and it seems a peculiar anomaly in 1927 still to find an attempt to perform such duties by the medical officer of health or the sanitary inspector.

Milk in Bottles.

Bottling of milk is not always carried out on the most hygienic lines and is apt to give a false sense of security to the public. A few of its disadvantages have lately been enumerated by Dr. E. G. Gibbs-Smith, who goes so far as to say that "the bottle in commonest use is thoroughly unhygienic. The narrowness of the neck of the bottle makes it difficult to clean the inside. The groove round the bottom inside edge, occasioned by the convex shape of the base, is a more serious objection, because it affords a place for the accumulation of congealed milk. But the worst defect is the groove constructed around the inside of the neck for the purpose of holding the disc in place. In this tiny hollow germs and dust inevitably collect. The method of sealing with a disc is bad in itself. The bottles are opened in 99 cases out of 100 by pressing in the disc with the finger and so letting into the milk whatever may have collected on the outside. The amount of dust which must accumulate when these bottles are left on the stairways of flats, at street doors, and in areas is obvious, and in addition, there is a grave risk of contamination by animals, male dogs especially." Dr. Gibbs-Smith mentions the difficulty of cleansing and sterilising these bottles where the cleansing is done by hand, and also gives an instance of what I myself have actually seen—a man refilling a bottle in the street from a can and sealing it with a disc from his pocket. Not long ago THE LANCET [2] reported a case in which the Brighton magistrates fined a milk roundsman for this offence, whilst a further instance was reported to me by a veterinary student who wrote: "It occurred about 10 A.M. one Saturday morning in a district of the North of London and I was an eye-witness. A milkman was standing by the side of the pavement with the usual milk cans on wheels, tap attached and all complete. The boy collected bottles from the houses as he went along, and brought them to the milk barrow, where the man deliberately filled them up again, and the boy put his hand into his greasy coat pocket, pulled out some of the round cardboard discs, and affixed them firmly with his dirty fingers. Replacing the full bottles on the barrow, the man proceeded on his journey and delivered them to his unsuspecting customers. The making of hygienic regulations is one thing, and their carrying out is another." We shall probably live to see carried out Dr. Gibbs-Smith's suggestion that distributors of milk should use some sort of cardboard container which could be used once and then destroyed.

Experience Abroad.

Last year I took a party of veterinarians to Denmark and Sweden with a view to getting first-hand information about the methods in use in those countries. We visited a number of farms, and in many of them machine-milking was the only method adopted. Those who owned the dairy herds spoke of it in the highest terms both from the point of view of cleanliness and economy of labour. In some of the herds the cows were milked three times a day.

Copenhagen, with over 700,000 inhabitants, is mainly supplied by the Copenhagen City Milk Distributing Company, who get their milk from about 3500 farms with an aggregate of about 55,000 cows. Stockholm, with some 450,000 inhabitants, derives most of its milk from a big coöperative farmers' and milk sales organisation, popularly known as the "Milk Central." The principles upon which they are run are very similar. Dairy farmers apply for membership and are required to hold shares in proportion to the average number of cows they milk. Interest is paid on the money invested and there is a fixed rate for the milk, with profit distributed in accordance with the quantities delivered. The organisation in Stockholm came into being in 1915 when there were 1523 members with an average of 22 cows each. In January, 1927, there were 7260 members, with an average of 12 cows each, so it will be seen that it is not all made up of large dairies. The hygienic control of the milk commences at the farms from which it is obtained, as all the cattle are examined once a month by veterinary surgeons who have strict instructions to deal at once with any sick beast and especially to be on the look-out for tuberculosis. The veterinary surgeon has to report upon the general cleanliness of the cows and the cowsheds and also upon the quality of the food given. Samples of milk are regularly sent to the laboratory to be tested in regard to appearance, taste, smell, purity, and fat-content. And after passing through certain cooling and cleansing processes on arrival at the depôt, the milk is put into sterilised bottles, capped, and despatched to the customer. Almost everything is done by machinery and neither the bottles nor milk are touched any more than is necessary by the hands of the milkers.

The Situation in England.

Although probably it would be correct to say that Denmark did a lot of pioneering, it would not be fair to give the impression that we are not moving in the same direction in Great Britain. Work on similar lines is being done by such companies as the United Dairies Company and others in our large cities. The part played by super-heated steam in sterilisation and its comparatively economical application is now so well understood, owing largely to the propaganda work of our large dairy companies, that the high-pressure boiler, with its steam pipes and sterilising cupboard and appurtenances, is installed as one of the first essentials in starting a successful dairy. The dairies supplying Manchester, Birmingham, Sheffield, and Edinburgh—to mention only a few of the large towns where properly organised inspection by medical and veterinary officials exists—are shining instances of the benefit which has resulted from collaboration over the question of clean milk between the two professions. This collaboration is essential, and the situation is in our hands if we assert our power and practise what we preach. No family would go against the word of its medical adviser, and the veterinary profession is prepared to work wholeheartedly to carry out the essential legal enactments. There could be no better illustration of the necessity for the collaboration of the two branches of medicine—human and veterinary. A great deal can be done to promote the production of clean milk if the practising doctor and the practising veterinarian, by being particular in regard to the milk they and their families drink, set an example to the public, and if they put in a word in season on every possible occasion. We have it in our power during the daily course of our lives to assist enormously by our words and actions the production of a clean supply of what is a necessity to the health of the nation.

DAIRY RESEARCH AND THE FARMER.

To the Editor of THE LANCET.

SIR,—As a farmer I am sometimes asked whether all the talk one hears nowadays about research in dairying is of any real interest to me, and whether I find that the work done at the National Institute for Research in Dairying at Shinfield, near Reading, is of any direct value. The general impression appears to be that this work is of interest only to a few wealthy people who farm for a hobby with a gay disregard of cost, and that well-groomed cows, with nicely washed udders, together with smart-looking milkers in spotless white overalls may look very well at an agricultural show, but can find no place in the routine of an ordinary farm. Most people are aware that, largely owing to the efforts of the staff at Shinfield, it is now possible to buy milk which is remarkably free from bacteria, and which is produced by cows which have passed certain tuberculin tests. But this super-milk is expensive to produce, and commands a high price, so that only a comparatively small number of people can afford to buy it. The greater part of the population is still consuming "ordinary" milk, which is sold with no guarantee as to cleanliness, and it is often asked whether the work of the Institute has any influence upon the production of this class of milk. The reply is a decided "yes."

It is unfortunate that, as a rule, the producer of "ordinary" milk is paid the same price per gallon, whether he makes an effort to keep it really clean or no, as a little encouragement in this direction would go a very long way. Luckily, however, cleanliness has several advantages from the farmer's point of view. Losses through milk turning sour become rare or disappear altogether, udder troubles are reduced, and the cowmen take a much keener interest in their work. Also in these days of over-production it is an increasingly important point that a farmer who has a reputation for producing really clean reliable milk can always find a ready market for it.

The National Institute for Research in Dairying owns a herd of cows, and farmers in the district are able to see for themselves that it is possible to produce really clean milk with little extra trouble and without expensive equipment or elaborate cowsheds. The methods in use have been evolved after some years of experience, and as they have always been subject to the criticism of visiting farmers they are simple and practical as well as efficient. Hence it is not surprising to find that they have been widely adopted in the district. Farmers are always cautious about taking up new ideas recommended by an institution which is not being run for profit, but when once the ideas have been put into practice by a few successful farmers and are reported upon favourably, the others are ready to follow suit. Thus the clean milk movement, which started slowly, has now gathered considerable impetus; more and more farmers are adopting the new ideas, and the general standard of cleanliness is much higher than it was a few years ago. The modern farmer's faith in the scientist is much greater than the general public realises or he himself admits, and the above indicates one of many ways in which the teaching of the National Institute for Research in Dairying is taking immediate effect, to the benefit of the farmer himself and of the general public.

I am, Sir, yours faithfully,

Tilehurst, Berkshire, Sept. 9th. DAIRY FARMER.

A PORTABLE ELECTROCARDIOGRAPH.

THE Portable Electrocardiograph which has been recently placed upon the market by the Victor X Ray Corporation, Ltd., is an interesting instrument in that it incorporates many new features. Whereas in the usual electrocardiographs the action current of the heart is recorded by an extremely sensitive galvanometer, in this the heart current is amplified by a special three-tube valve amplifier, and is recorded by a ruggedly constructed galvanometer of the mirror type. The principle of amplification of low potential currents prior to recording has been used for some years past by experimental physiologists, both in this country and the United States, but, while inherently successful, the practical difficulties have required much patience and care. The present instrument is said to be extremely simple in operation, and requires no special treatment; it is portable though heavy, and wherever it is placed, there it is said to function satisfactorily; the jar and vibration of transport do not affect it. The makers state that the deflection time is 0·001 second or less—an extremely short period; and it is a pity that definite evidence of this feature is not available. There is no separate time marker, the motor controlling the film being held capable of such uniform speed that the time intervals can be measured on an auxiliary scale which is supplied. This, from the point of view of accurate time measurements, is a grave disadvantage. The general advantages that the makers claim beyond those already noted are that no compensating resistance device for the patient's skin resistance is necessary, that it can be used in daylight, the records are free from confusion owing to the absence of vertical and horizontal lines, and that it avoids the troubles associated with a sensitive string galvanometer. It is an instrument which is interesting because of the many new features, but at the moment there is no evidence available that several of the special claims made by the makers are justified, and they remain to be verified by experience. The price is not yet fixed, but is said to be about £400. The address of the makers is 314–322, Regent-street, London, W.1.

THE ROYAL FREE HOSPITAL.

To the Editor of THE LANCET.

SIR,—It is just 50 years since the Royal Free Hospital opened its wards for the clinical instruction of the students of the London School of Medicine for Women. During this period the development of the hospital has led to many changes. In 1877 there were just over 100 beds; now there are 268. These include 68 beds in the unit of obstetrics and gynæcology, and 20 in the children's wards. The Royal Free was the first hospital in England to have a unit of obstetrics and gynæcology, and is, I think, still the only general hospital which provides accommodation for venereal obstetric cases. In 1877 the out-patient department was held in the basement of the hospital; now there is a spacious out-patient hall, with airy, light consulting rooms, each supplied with several small rooms for the examination of patients. The casualty department was formerly a small room at the gate; now there is a good waiting hall with adequate accommodation for the examination and dressing of the patients, a casualty theatre, and four observation beds, two for men and two for women. The hospital now has a cardiograph room, X ray and treatment rooms, an electro-therapeutical and massage department, light treatment, orthopædic and dental departments, and many other special departments. The "Alfred Langton Home" provides a bedroom for each nurse, with large recreation and sitting-rooms, and a dining-room with small tables. The Home is not yet completed owing to lack of funds, and some 50 nurses sleep in houses in Mecklenburgh-square, and a few in the main hospital. It is desired to complete the nurses' home at the earliest possible moment. Nine private wards have been provided in the hospital. These are in constant demand, and the honorary staff greatly desire that they may be doubled or trebled in number. This could be done if the nurses' home was completed. The annual cost of the hospital has increased from £7200 to £72,000, partly due to the increased price of all goods and salaries, and partly to the increased number of beds.

I should be glad if former students who visit London, and others interested in the development of this hospital, will let me know and I will arrange for them to see it. Contributions from any readers of THE LANCET would, at this time of remembrance, be warmly welcomed.

I am, Sir, yours faithfully,

Gray's Inn-road, W.C., Sept. 22nd. MAY THORNE, Hon. Sec.

*** The address of the Royal Free Hospital Centenary Appeal is 24, Mecklenburgh-square, London, W.C.1.—ED. L.

John B. Murphy Oration

ON THE

BIONOMICS OF ANIMAL REPRODUCTION

IN RELATION TO TUMOURS AND CANCERS.

Delivered at Detroit, Michigan, on Oct. 3rd, 1927,

BY SIR JOHN BLAND-SUTTON, BART., F.R.C.S. ENG.,

CONSULTING SURGEON TO THE MIDDLESEX HOSPITAL.

The Theory of the Origin of Man from lower animals finds its surest foundation in Embryology, and some remarkable observations and discoveries relating to Tumours are concerned with this branch of Biology.

THE greatest discovery man ever made about himself was when Von Baer in 1827 discovered, with the aid of a microscope, the human ovum. When ripe the ovum is a spherical cell 0·25 μ in diameter. The riddle of animal reproduction remained unsolved until Koelliker recognised the importance of the minute flagellate cells called spermatozoa. These remarkable cells were discovered by Hamm, a pupil of Leeuwenhoek, in 1677. They resemble protozoa, and were called spermatozoa. For many years they were regarded as parasites of semen until Wagner and Koelliker in 1844 proved them to be histological elements of the testis. No one has witnessed the union of a spermatozoon with a human ovum; it is a matter of inference from observations made on the eggs of starfishes and amphibians. In such creatures ova and spermatozoa mingle in the water and come into vital collision, and the act of fertilisation can be seen under conditions permitting accurate observation. Biologists who have studied the process of fertilisation notice that when mature ova are brought into the vicinity of sperm, the spermatozoa, influenced by their presence, make energetic efforts to reach them.

THE AQUATIC ORIGIN OF MAN.

There is good evidence that man is derived from aquatic ancestors; the stages he passes through before becoming fit to be born indicate this: the fœtus in the womb lives as an aquatic parasite within its mother. When an ovum enters the uterus, the overgrown uterine decidua on which it rests secretes a fluid for its nourishment. This fluid is aptly named by Teacher, in a recent admirable research, uterine milk. The ovum can flourish in this medium about ten days. When the environment is favourable fertilisation is effected by a spermatozoon—a flagellate cell flourishing in a fluid menstruum. The ovum, in consequence of its union with the head of the spermatozoon, becomes an oösperm, or zygote, and is quickly invested with delicate membranes. Of these, the outer, known as the chorion, quickly becomes shaggy with protoplasmic bodies called chorionic villi. These villi erode the adjacent decidua and firmly embed the oösperm; they are, in due course, converted into a placenta—the respiratory organ of the fœtus. Fluid accumulates in the amnionic cavity and in due course the embryo disports itself actively as an aquatic creature in its own amnionic pool. In the early stage its skin is covered by a single layer of cells. Later this becomes double and the superficial layer is known as the epitrichium. About the eighth month of intra-uterine life the epitrichium is cast off mixed with grease from the skin-glands, and the delicate hairs known as lanugo. This soapy stuff is the vernix caseosa so conspicuous on the skin of the new-born child. The epitrichium persists on aquatic creatures such as frogs and salamanders and protects their skin from maceration. When the human fœtus, as an aquatic creature, disports itself in the amnionic hydrosphere the epitrichium and vernix caseosa protect it from maceration. Occasionally the epitrichium persists and the fœtus dies; in such circumstances when discharged from the uterus, it presents a weird appearance and is known as the Harlequin fœtus.

The human fœtus is an aquatic mammal, its blood being oxygenated by its mother's blood by means of the placenta. At birth it is expelled from the uterus; discards the placenta, and becomes a lung-breathing creature.

Few things made a deeper impression on my mind that when, as a child, I realised that the tadpoles, which emerged from the frog-spawn in the ditch bordering my playground, turned into frogs and jumped among the long grass in the paddock. It was my earliest lesson in embryology. When I became absorbed in anatomy and morphology the changes in the branchial bars, as the aquatic tadpole transforms into an air-breathing amphibian, became more interesting, especially on learning that in man their chief representatives are the delicate chain of ossicles—malleus, incus, and stapes—in the tympanic cavity. It requires little imagination to realise that "the first landmark in the ascent of man was when the frog first found voice and left the water," but true to its origin, *the frog must return to the water to spawn.*

Recently Leathes,[1] in an admirable summary, concludes that life consists in organic compounds continually reforming themselves and that the sea is the native environment originally of all forms of life. The importance of water is emphasised by the knowledge that the greater part of our bodies (two-thirds) is water.

CHORIONIC VILLI.

An ovum is propelled through the Fallopian tube in about three days. Normally the life of the ovum is spent in the cavity of the uterus, a suitable place for its reception and nourishment. When an ovum is attacked by a spermatozoon it burrows into the endometrium like a vigorous parasite. The initial effect of this invasion upon a woman is immediate arrest of menstruation; no one has suggested an explanation of this remarkable effect.

Thirty or forty days after fertilisation the oösperm has undergone some wonderful changes. It has increased enormously and become a cyst with a thin delicate transparent wall containing a visible embryo, and its outer wall is shaggy with delicate tufts known as chorionic villi. In the early stages the villi are devoid of blood-vessels; they consist of an axis of delicate connective tissue supporting cells rich in protoplasm. These cells are peculiar in character and easily recognised with the aid of a microscope by competent histologists. The chorionic villi are the chief cellular elements of the placenta. The cellular caps of the villi possess erosive powers which enable them to erode maternal tissues and blood-vessels. Chorionic villi have become the subject of intense study. A century ago it was discovered that the curious product of conception known as the grape-mole (Trauben mole) is due to changes in the chorionic villi. Examples are preserved in most pathological museums. Scientific knowledge percolates slowly; this disease remained a curiosity until Sänger and Pfeiffer, in 1889, independently described a malignant type of uterine tumour, peculiar in structure, which attacks parturient women. Subsequent investigations by many observers proved that such perversion is associated with the chorionic villi. It is now well known as an exaggeration of the eroding properties of the villi; they penetrate the walls of the uterus and may invade the peritoneal cavity. When they erode blood-vessels, fragments of the villi are deported by the blood stream to the heart, lungs, bones, viscera, and brain, giving origin to "secondary deposits" and sometimes kill the patient with astonishing speed.

Examples of the spontaneous disappearance of chorionic cancer have been reported. This betrays

[1] THE LANCET, 1926, ii., 365.

its alliance with the placenta which is a temporary organ.

The natural history of chorionic villi illustrates in a remarkable way the distinguishing features of the cancer cell; for example, its power of independent growth, erosiveness, and vitality which enable it to undergo dispersion and establish itself in parts of the body remote from its origin.

The natural history of the placenta is astonishing, but facts have been gradually accumulating which increase our astonishment.

The placenta dominates the life of the fœtus; the termination of its intra-uterine life coincides with that of the placenta, and at the end of 280 days, if the child be not expelled, the fœtal circulation stops, the babe dies, the placenta dies, and is slowly absorbed. It is significant that a ripe placenta never becomes malignant. The villi—the immature elements—are the source of chorionic cancer.

The pathologist's interest does not end here.

OVARIAN DERMOIDS.

Misdirected Embryologic Energy.

When the wonderful effects which follow the vital collision of a spermatozoon with an ovum were unravelled by embryologists, the spermatozoon seemed to be the essential factor in initiating developmental changes in the ovum. There are reasons for believing that this privilege is not peculiar to the tailed-cell. Ovarian dermoids are familiar to surgeons to-day, but 50 years ago they were regarded as curious tumours usually found after death. With the establishment of ovariotomy they were proved to be common tumours; all organs normal to a fœtus have been found in them, except the reproductive gonads. Skin with all the elements common to it, lanugo, hair, glands, and nails. Brain tissue, choroid plexus, and spinal cord. Eyes, teeth, cartilage, and bone. Trachea with mucous membrane and thyroid gland. Intestine and liver. The essential element is a skin-covered lump which often resembles a mammary gland with a nipple surrounded with an areola. Sometimes a rudely shaped head and a stunted limb. These ill-formed lumps, known as embryomas, represent an ovum which has developed without the stimulus of a spermatozoon.

Whilst pathologists were puzzled by such occurrences, Loeb induced the eggs of starfishes to segment by adding soda-water to the sea-water of an aquarium—shock fertilisation. Later, Batallion induced complete embryogenesis in the eggs of grass frogs by gently puncturing them with extremely thin metal, or glass stylets dipped in frog's blood. It is now a common experiment in biological laboratories in springtime to produce "fatherless frogs." These experiments have an important bearing on the origin of ovarian dermoids and support the opinion that they are due to the activity of ova.

The nature of ovarian dermoids has engrossed my attention for nearly 50 years. These tumours in some instances weigh nearly 50 lb. Gradually I realised that the mass of grumous stuff which often forms the greater part of the tumour is excrementitious. The embryoma, the essential part of the tumour, is skin-covered and the skin sheds epidermis, lanugo, hair, sebum, &c., hour by hour, day by day, month by month, and year by year, until the accumulated rubbish makes the tumour conspicuous.

I have often wondered at the frequent presence of skin, hair, and teeth in dermoids and pondered on the absence of intestine. How blind have I been!

A peculiarity of the cubical cells lining the gastro-intestinal canal is the large amount of colloid material which forms in them under pathological conditions. The biggest tumours which form in women are ovarian dermoids. Many years ago I urged that the membrane lining the honeycomb chambers of these huge cystic masses was mucous membrane. Gradually I became convinced that they are embryomas in which gastro-intestinal epithelium is dominant.

In ovarian dermoids skin prevails, and the accumulated rubbish—sebum, epidermis, lanugo, and teeth—is detritus from the skin.

In ovarian colloid cysts mucous membrane prevails. The accumulated stuff is pseudo-mucin furnished by the gastro-intestinal epithelium of the embryoma.

Between the extreme types there is every gradation of misdirected embryologic energy. These tumours arise in ova which develop independently of spermatozoa. When an embryoma is well organised the character of the dermoid is easily recognised and it is non-malignant. They endanger life by their bulk and septic infection to which they are liable, usually from the intestine.

Although I have spent much time in studying the minute structure of ovarian dermoids I have not detected in them any evidence of testicular tissue or chorionic villi. In 1902 Schangenhaufer discovered in a testicular dermoid tissue identical with chorionic villi. His observations have been confirmed by other histologists. In some instances the tissue closely resembles that of the grape-mole.

It is worth mention that among the peculiar tumours which occur in the ovaries of adult women, known as papillomatous cysts, there is a variety in which the microscopic structure is like that of chorionic cancer. This variety is malignant and is disseminated by the blood stream. The secondary tumours erode bone with facility. In one example under my observation the secondary growths occurred in the superior mediastinum, and bud-like processes eroded the manubrium of the sternum, and appeared as currant-like nodules under the skin.

Papillomatous cysts of the ovaries are, as a rule, bilateral and occur in women between the twenty-fifth and fiftieth years of life.

It is difficult to escape from this conclusion:

PREGNANCY IS THE EPITOME OF A PARASITE INFECTION.

The fœtus may be regarded as a tumour growing within its mother, the consequence of an infection by a parasite—the spermatozoon. It is a strange eventful history. Copulation is the method of infection by which flagellate protozoa—spermatozoa, introduced into the female—attack ripe ova in the uterine or the tubal passages, and convert one or more into oösperms (zygotes). The oösperm embeds itself vigorously in the ripe decidua. The first effects of the infection are a local reaction—the arrest of menstruation; and a constitutional response expressed by mammary activity—the secretion of milk; and usually pigmentation of the skin localised to certain definite situations. The uterus, in a marvellous manner, adjusts itself to the growth of the fœtal tumour, and at the end of 280 days the death of the placenta coincides with labour and the expulsion of the fœtus and its membranes. The fœtus discards the placenta and becomes an air-breathing mammal, leads an independent life, becomes in due course mature, and seeks opportunities for reproducing its kind.

Pathological changes sometimes arise in connexion with the accessory structures, especially the chorionic villi and the placenta, which jeopardise the successful development of the embryo and the life of its mother. We know in relation with ovarian and testicular dermoids that the more complete the development of the embryo the less harmful are the consequences to the mother; but when the development is perverted and the tissues nondescript, the gross products are often notoriously malignant. This holds good for uterine development.

PARTURITION.

Childbirth is a natural operation, and like a surgical operation has its risks and sequences. Of these, the two most important are sepsis and cancer, one is immediate and the other deferred.

In spite of the brilliant results which ensued on the conquest of sepsis and the treatment of wounds, child-bed fever persists. It is true that endemic

puerperal fever disappeared when Listerian principles were applied, but the sporadic form persists, and will persist, until parturition is conducted on the same strict methods as surgical operations. Take, for example, Cæsarean section. In 1860 this ancient operation had an enormous mortality. To-day it is safer than normal delivery at term, since surgeons adopted aseptic methods—boiling instruments and ligature materials; and especially wearing sterilised rubber gloves when conducting labour.

In order to reduce the risks of parturition to the level of those attending surgical operations, a parturient woman should be treated on the same lines as a prospective surgical patient. *She should not be ashamed to wash the gate-of-birth with the same diligence and care as she washes her face.* Such toilet is of the utmost value as a protection against post-partem sepsis.

Chronic ulcerating septic fissures in the walls of the birth-canal are the lurking places of pathogenic germs, and potential sources of uterine infection and cancer.

Science hath given a new commandment to doctors and midwives:

> Thou shalt wear sterilised rubber-gloves in taking a labour. The Law will not hold him guiltless that taketh a labour with bare hands and the lying-in woman develops child-bed fever.

We flounder in speculation concerning the causes of tumours and cancers, as much as our predecessors floundered in ignorance of the factors concerned in animal reproduction, until the microscope enabled us to recognise mammalian ova and spermatozoa, and work out their intimate relations.

> Verily the tale of Animal Reproduction is the most wonderful history in the world.

An Address
ON
PRACTICAL ANÆSTHETICS IN CHILDREN.

Delivered at the Infants Hospital, Westminster,

BY JOSEPH BIRT, M.R.C.S. ENG.,
ANÆSTHETIST TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON, AND TO THE INFANTS HOSPITAL, WESTMINSTER, ETC.

TWENTY-FOUR hours before operation the child's urine should be tested for albumin, sugar, and acetone. Whether the latter be present or not, teaspoonful doses of dextrose should be given, in addition to usual food, every four hours until within an hour of the operation. For old enough children sucking barley-sugar, or an equivalent, is an efficient and pleasant alternative. Status lymphaticus often cannot be diagnosed, but the anæsthetist should beware of children showing apathy and not resisting during induction, especially if they are fat and pale. Solid food should be discontinued four hours before the operation. No preliminary purgation is desirable. Atropine should be administered, either by the mouth or hypodermically—if by the mouth in two doses, one two hours and the other half an hour before operation, in the following scale of doses:—

For a child of 6 months to 1 year, in all ..	1/250 gr.
„ „ 1 year to 2 years, in all ..	1/150 gr.
„ „ 6 years and upwards, in all..	1/50 gr.

If by hypodermic injection half an hour before operation:—

From 6 months to 1 year ..	1/400 gr.
1–4 years	1/150 gr.
4–12 years	1/100 gr.

I think the hypodermic method is better as its action is more definite and is easier to time. In a few cases atropine administered orally has given rise to symptoms of poisoning which, so far as I know, have not been observed when a proper dose has been given hypodermically.

Apparatus.

Two inhaling masks should be used. I prefer Page's as they are fitted with two separate tubes, one for the gaseous anæsthetic and one for oxygen, each covered with 24 layers of single gauze. (Gauze is usually folded four times in the bought rolls, therefore six thicknesses of this will make 24 layers.) A pad of Gamgee tissue about 9 in. by 6 in., with a hole cut in the centre for the nose and mouth, should be wetted and placed over the face to protect the eyes, and this again covered with a similar-sized piece of thin indiarubber to act as an ether-proof protective. A tube of ethyl chloride, an ether bottle fitted with a dropping cork, and an ether bottle in a fixed stand with a Mennell's regulating tap should be provided, as well as a cylinder of oxygen with a fine adjustment screw, some indiarubber bellows, and two or three lengths of indiarubber tubing of a suitable size, in all about 3 yards long, a Mason's gag, and tongue forceps made much like towel-clips. The old-fashioned tongue-crushing clips should never be used. A small cylinder containing CO_2 may be found useful if respiratory amplitude should need increasing.

Ether Anæsthesia.

For an infant under 6 months ethyl chloride can be dispensed with and the gauze mask well soaked with ether and placed about 4 in. from the infant's face, gradually decreasing this distance till there is no struggling or crying. Then a wetted Gamgee shield, the indiarubber, and the mask are put in position, and the head turned well round to one side so that the tongue may fall into the cheek and saliva run out of the mouth instead of around the epiglottis and so into the larynx. I use gauze because it is absorbent and porous (as is also coarse flannel); lint is apt to balloon in expiration. The wet Gamgee pad fits the face better and does not give off fluff, which might be inhaled; the dampness also dilutes any ether that might escape on to the Gamgee, so that it is less likely to injure the eyes.

It is pleasanter for older children to start with a small dose of ethyl chloride to stop the crying and struggling that might be prolonged under ether alone. The nurse must hold the child securely (preferably above the elbows) while a gauze-covered mask is placed over the child's face after it has had about 5 or 6 c.cm. of ethyl chloride sprayed into it. Ether is dropped over the mask which the hand partly covers. When the child is asleep the gauze and indiarubber pad and the second gauze-covered mask (with plenty of ether on it) are firmly applied. This removal of the first mask takes away the stale and sickly gas left by the ethyl chloride and tends to prevent vomiting.

Readiness for operation is best shown in infants under one year by the absence of response when the skin of the abdomen is picked up with towel-clips, and in older children by freedom of the lower jaw when pulled away from the upper. The anæsthetic may then be continued by gradually dripping ether on the mask, keeping it quite wet all over and covering it with a thick extra pad of gauze or about two layers of an old soft bath towel. The ether should be dripped on the gauze of the mask beneath the extra covering, which confines the vapour and prevents evaporation and the extreme cold which it causes. The anæsthetic may very conveniently be continued from the completion of induction, for all ordinary purposes, by means of a gentle stream of oxygen passing through ether and conveyed to the patient by a tube from the Mennell's tap in the bottle to one of the conducting tubes on Page's frame-mask. The relative amount of ether and oxygen is regulated by the peculiar advantages of this tap. The oxygen (or, if preferred, air by means of bellows) passes from the other side of the tap. When the anæsthetic is being administered in this way a thoroughly fresh

supply for each patient should be insisted on, to ensure the minimum toxic effect from chemical changes. Absolutely fresh anæsthetic should be put into the bottle for each new patient. The residue can be used up for cleaning or for making ether soap. Ether and chloroform, especially in clear glass bottles, should be kept in the dark.

Hot air is not refreshing to breathe, and some surgeons believe that bronchial catarrh is more usual after using the anæsthetic warm.

Note must be taken of the quality of the pulse (rate is always much increased, often 156 or more), the breathing, the condition of the pupils and eyes generally, the colour of the lips and skin of the face, and always of the blood at the site of operation. The operation should not be commenced until the patient has passed the troublesome and even dangerous time when the reflex governing the vocal cords is sufficiently active to excite laryngeal spasm. This is especially dangerous with such a toxic agent as chloroform, which, when locked in the system by laryngeal spasm, will soon poison the vital organs of the body. Chloroform should never be used for children except in operations involving the use of an actual or electric cautery in the region of the mouth or face. It should then be delivered through a Junker and by air bellows, avoiding oxygen.

To proceed with the administration after the induction is properly completed, very little oxygen and ether will be necessary for good anæsthesia and very even and satisfactory states of the pulse and respiration. The pupils should be moderately dilated and the jaw kept loose by increasing, if necessary, the proportion of ether used.

After-treatment.

To free the patient from ether saturation at the conclusion of an operation CO_2 is sometimes used to induce voluminous and slow respiration. It is said that the patient has less taste of ether when he recovers consciousness. Some people think that the after-smell and unpleasantness of ether are neutralised by placing over the patient's face after operation a square of thick gauze soaked in household vinegar; presumably there is a chemical change which converts the unpleasant taste of ether to a pleasant one. During an operation and after it, until the patient coughs or vomits, the head should be kept on one side and low, without a pillow, to prevent the tongue falling on the epiglottis, and to allow all oral secretions to run out of the lower angle of the mouth. When the coughing or vomiting reflex is re-established, the patient will unconsciously look after himself and can be safely placed in any position desired.

Cranial Operations.

For operations involving the cranium, the neck (such as one for glands), or the region of the thyroid, it is necessary for the anæsthetist to be out of the way of the surgeon and his assistants, and this can be very satisfactorily managed, after induction is completed, in one of the following three ways.

1. An indiarubber nasal tube is passed to the back of the nasopharynx (preferably on one side only, leaving the other nostril free for expiration) and securely fastened to the face outside the nose by strapping. The main efferent tube from the ether container is attached to the nasal tube by a small junction of lead piping; lead is always preferable to glass for junctions as it does not break, is cheap, and can be bought at any plumber's shop. The main tube delivering the anæsthetic from the apparatus should be about 3 ft. long, so that the apparatus itself can stand away from the field of operation. It is important to see that the patient's end of the tube cannot slip off as it might be very difficult and inconvenient to replace in the middle of an operation. The anæsthetist must watch the bubbling in the sight-feed bottle and give proper consideration to the amount of ether being used.

2. A special airway can be passed over the tongue and secured in the mouth by strapping over it a pad of gauze partially occluding its outer end. This airway has a central tube for inspiration and the attachment of the efferent ether tube, while there is space enough around the centre tube for very free expiration and some measure of inspiration as well.

3. By the intratracheal method the anæsthetic is supplied in exactly the same way as in (2), but the tube finally delivering it is passed through the glottis. The passage of the tracheal catheter is not always easy, even in skilled hands, and as some injury may be caused by it or by the anæsthetic vapour impinging on the delicate mucous membrane, the intratracheal method should be reserved for special cases—e.g., when it is necessary to keep the lungs blown out to prevent pulmonary collapse, or in removal of tumours of the ethmoid or sphenoid regions, when the surgeon might find it necessary to divide and separate the soft or hard palates. For some purposes a combination of nitrous oxide and oxygen, with or without a small quantity of ether (derived by passing the gases either through or over the ether in the container) is very successful, especially in Rammstedt's operation. The apparatus is very heavy and therefore difficult to transport.

Boyle's apparatus is illustrated in most catalogues and is very efficient. It is desirable to have the gases in two or preferably three cylinders, rather than in one, in case of accidental leakage. There should be also an extra sight-measure bottle and an ether-containing bottle, as a failure of supply in any of these details might spell tragedy.

Each cylinder has a valve operated by a key and a fine adjustment wheel at the top to allow the quantity of gases required to be very delicately regulated. The sight-feed bottle contains two vertical tubes, the lower halves of each pierced with five small holes at regular intervals from top to bottom. To the afferent or external orifice of one tube is fixed an indiarubber tube from the oxygen and to the other a similar tube from the N_2O cylinder. Above the top holes is an air space in the bottle for mixing the gases, and up to this point cold water is poured in. The gas arriving from each cylinder bubbles through its respective tube into the water and indicates the quantity emitted in bubble units. As an ordinary rough rule it may be taken that one bubble of oxygen should be evident for four bubbles of N_2O. This mixture of gases passes into an ordinary three-way-valve gas-bag as used for dental administrations, but the bag has a central indiarubber tubing which is so arranged that any change made in the mixture of the gases is immediately conveyed close to the patient's mouth, while the residue inflates the bag.

The bag is filled and a suitable face-piece placed on the face as explained above. The child breathes with the valves in mid-position, which means inhalation of gases from the bag and expiration into the air. After a few breaths of this the ether tap is turned so that the gases pass over it, but not through it, and the valve is closed to rebreathing position. After a short time the child ceases to struggle and cry, and then the N_2O and oxygen alone are given and continued till the corneal reflexes are lost. When induction is complete the valves are returned to the midway point, as a cleaner and a better anæsthetic is thus administered than by rebreathing. In abdominal operations it is well to let more ether enter the bag when the peritoneum is about to be opened; should there be any sign of protrusion of the abdominal contents, it is well to have the wound covered up and to deliver the ether by bubbling the gases actually through it. This, however, is not usually necessary if the induction has not been hurried; in fact, it is a great help to the anæsthetist to have a quarter of an hour for induction so that it may be very gradual and cautious. One bubble of oxygen and four of N_2O in the sight-feed are usual, but must always be modified to suit each individual case.

When the operation is over the patient will soon be on his way to recovery of consciousness, and therefore in all operations (especially orthopædic procedures involving after-pain) he should have an adequate sedative, either morphia (hypodermically or orally) or aspirin and glucose by the rectum; the latter, however, does not act quickly enough after gas and oxygen. If the lips are anæmic they should be rubbed briskly

with a soft towel and a teaspoonful of brandy gently trickled between the lower lip and gum, or the finger may be wetted with brandy and placed in his mouth; no matter how young the patient is he is usually quickly refreshed. All the above anæsthetics can be continued after the requisite induction from a large gas and oxygen and ether apparatus, containing big cylinders and sufficiently capacious measuring and ether-containing bottles, such as is now installed at Great Ormond-street Hospital. Intratracheal work can also be done from it without separate motors and other complications. This apparatus has an extra cylinder containing CO_2 attached to the stand, with a special tap for running it in with the other gases if the CO_2 of the blood is considered subnormal, but this must be done with great care to avoid CO_2 poisoning. A gauge is fitted to this stand for measuring intratracheal pressures.

For intratracheal work a railroad catheter with the hole at the end should be used. The child's body and head lie quite flat and supine during induction. A special larnygoscope with the light fixed in its distal end is passed over the tongue to the epiglottis, tilted forward, and pushed to the aperture of the glottis; the catheter is then passed without force, and the ether vapour tube attached. The gauge register should be at 0 on inspiration and at 10 to 15 mm. during expiration. The catheter sizes are roughly as follows: No. 12 for a child of 12; No. 9 for a child of 6; No. 5 for babies. In extensive operations on the chest, when both pleuræ are opened, a pressure of about 50 mm. must be maintained to prevent pulmonary collapse.

Nitrous Oxide and Ethyl Chloride.

N_2O alone is not a satisfactory anæsthetic for children. Induction tends to be very quick, occasionally with much jactitation, and the return to consciousness is too rapid. The addition of a small proportion of oxygen, as explained before, meets this inconvenience quite adequately in all cases except when the mouth is the operation area. If the operation is to be a prolonged one ether vapour will be necessary, but where teeth are to be extracted or tonsils removed by the guillotine ethyl chloride should be used and is best administered by the closed-bag method, provided the anæsthetist has had a proper course of practical training in the necessary details of technique. Ethyl chloride should, however, not be administered either by the open or closed method until thorough practical experience has been obtained. Where the mouth or face is the site of operation, the ether vapour must be conveyed to the angle of the mouth by a bent lead tube attached to the indiarubber conducting tube, or a nasal catheter passed into one nostril and likewise attached to the conduction tube. At the completion of all operations it is well to put a little castor-oil into the eyes to prevent soreness of the conjunctiva. Even if the anæsthetic does not actually drop or creep into the eyes the atropine diminishes the flow of tears and thus leaves the conjunctiva very sensitive.

Accidents.

Accidents during anæsthetics are so rare and unexpected that it is important to have fixed in one's mind the best and first things to do under such circumstances.

Respiration may stop for a considerable time so long as the heart is actually pumping, but the limit allowable for real cardiac failure must not be more than seven minutes. It is best, therefore, to regard the situation as one of cardiac failure immediately untoward signs or symptoms appear. The child should be inverted or nearly turned upside down by tilting down the head of the operation table, the head should be hyperextended, the tongue drawn out, or the epiglottis pulled forward by a finger in the mouth, and oxygen driven in fairly forcibly through the nose or mouth. At the same time someone should perform external heart stimulation by a forcible and fairly quick intermittent pushing up under the left ribs of the contents of the abdomen. A nurse should inject 2 or 3 gr. of camphor in oil subcutaneously or intramuscularly. Artificial respiration can be conducted by another assistant, and the moment the heart responds it will be further stimulated by the presence of oxygen in the lungs and blood. If these measures fail the surgeon will open the abdomen and massage the heart immediately through the diaphragm. The first thing and most essential point is to arouse the dormant heart through the left abdominal wall.

Tests for Acetone.—Sodium-nitro-prusside test. To one inch of urine add two or three drops of caustic soda, then 1 per cent. solution sodium-nitro-prusside drop by drop = ruby red colour, add acetic acid; if acetone be present colour equals deep port wine.

Treatment for Acidosis.—Warmed 2 per cent. glucose sterile solutions under the skin or into a vein, or if by the rectum 15 per cent. solutions.

A CASE OF
VIRILISM DUE TO AN ADRENAL CORTICAL HYPERNEPHROMA:
RECOVERY AFTER REMOVAL OF GROWTH.

BY C. G. MURRAY, M.D. EDIN.,
AND
GRAHAM S. SIMPSON, F.R.C.S. ENG.,
SENIOR SURGEON, ROYAL HOSPITAL, SHEFFIELD.

With a Pathological Report by Dr. HUMPHREY GLEAVE *and Remarks by* Prof. ARTHUR HALL.

UP to 1925, when Gordon Holmes [1] published his case of virilism in which an adrenal growth was successfully removed by Sargent, in only two other cases had a similar operation been successful The earliest of these cases was J. K. Thornton's,[2] in which recovery was complete, but there was an intraperitoneal recurrence two years later. The other by Collett,[9] of Christiania, published in 1923, was in a child. We have been able to find records of only two more cases since 1925. In the case described by Fawcett, Hadfield, and Phillips [4] the patient was a woman of 70 in whom intestinal obstruction was caused by a very large tumour arising from congenital bilateral hyperplasia of the suprarenal cortex. There were "abnormalities in sexual character of the hormonic pseudohermaphroditic type." The operation was merely one of urgency, and the patient died on the next day. Feinblatt's [8] case was a woman aged 32. The history was somewhat similar to that in the case recorded in this paper. She began with pains in the right lumbar region which kept recurring for some weeks, then disappeared, to be followed about three months later by the changes in secondary characters typical of adrenal cortical growth. In this case, however, there was marked wasting and rapidly progressing weakness, and death occurred from exhaustion in about seven months from the first onset. The tumour was found to be a carcinoma of the cortex of the right adrenal gland with extension by way of the vena cava, but without metastasis. No operation was performed.

History of the Present Case.

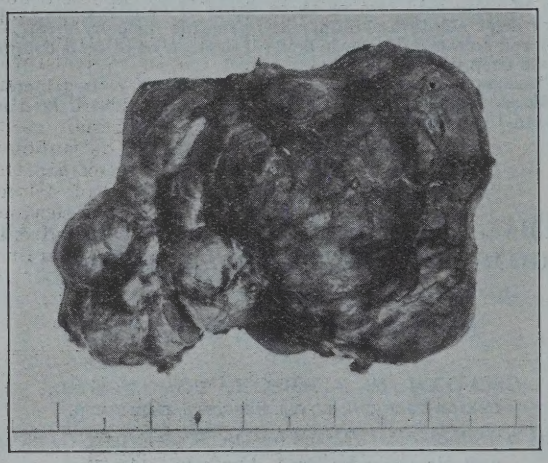
The following is the history of the case:

A single woman, aged 36, whose previous health had been quite good, began to have attacks of severe abdominal pain two or three years ago. They recurred at intervals of a few weeks, and were accompanied by anorexia. These have recently become less troublesome and gradually disappeared.

In May, 1926, she missed a period. There had never been any irregularity of the menses before. They had always occurred at intervals of exactly 28 days. During the summer of 1926 she also noticed that she was changing in several respects. She increased in weight. The hands and feet were getting larger, the hair of the scalp was beginning to fall off quite considerably, the skin of the face was becoming more coarse, and a strong hairy growth appeared on the face, chin, and lips. She also began to lose interest in things, and became irritable and depressed.

As the menses had not reappeared she consulted a gynæcologist in September, 1926. A pelvic examination was made, but nothing was found definitely abnormal. The uterus and ovaries were small. There was no marked enlargement of the clitoris. During the examination, however, a swelling was found deep in the right loin, which was suspected to be renal. In November, 1926, whilst staying in London, she consulted Dr. H. W. Barber about the hypertrichosis of the face, which was becoming more

FIG. 1.



Naked-eye photograph of larger tumour.

unsightly. He recognised the condition as one of early virilism, and suggested that the tumour which had been felt in the right side of the abdomen was a hypernephroma, causing the symptoms. He also called attention to the high blood pressure (200 systolic, 120 diastolic) present when he saw her.

She returned home, and her condition on Nov. 12th was as follows. The general appearance had become gross and unsightly, the features florid and bloated. The cheeks, lips, chin, and neck showed a growth of dark bristly hair. The hair of the head had fallen off from the crown and temples, giving the baldness characteristic of a middle-aged man, the breasts had shrunk, and there was a suggestion of the male type of figure, apart from the legs. The hands and feet were definitely enlarged. There were also definite temperamental changes noticeable to herself as well as to those around her. From being a placid and comfortable person she had become irritable and depressed. She complained that she had lost all interest in life, that all her previous emotions and affections had disappeared. Her clothes and her personal appearance no longer afforded her any pleasure. She also stated on inquiry that the opposite sex had ceased to have any attraction for her; in fact, that men's society had become somewhat distasteful to her. This, however, did not seem to be a prominent symptom, and she thought it was only part of her loss of general interest in everything. On physical examination, in addition to the characteristics of virilism mentioned above, a definite tumour was felt deeply in the right loin. It was firm, rounded, and slightly tender on pressure.

The pulse-rate, which had been 110, fell to 80 after a two weeks' rest in bed. The blood pressure was still high, usually about 200 systolic and 120 diastolic. The cardiac impulse was considerably displaced outwards and definitely heaving in character. When the patient was up there was some œdema of the right leg only. Nothing abnormal was found in any other system. The urine contained neither albumin nor sugar.

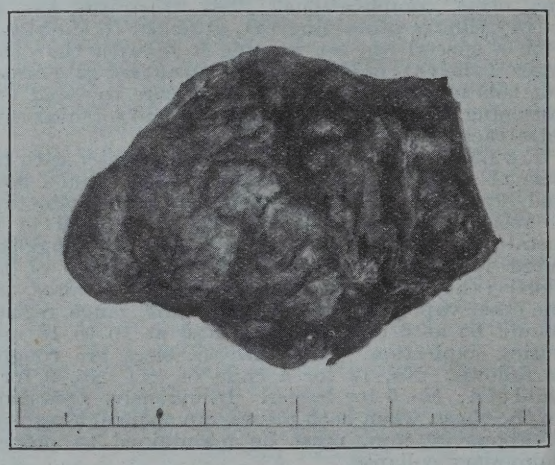
Operation.

After a consultation with Prof. Arthur Hall on Nov. 12th, operation was decided upon.

As a preliminary to this a cystoscopic examination was made by one of us (G. S. S.) to determine the condition of the right kidney. The bladder and ureters were normal. Blue was seen coming from the left ureter, but whether from the right or not remained uncertain.

On Nov. 16th, therefore, after anæsthetisation, a confirmatory cystoscopic examination was done, which showed that blue came also from the right kidney, but to a somewhat less extent than from the left. The major operation was therefore proceeded with (G. S. S.). An oblique incision was made in the right lumbar region and part of the right twelfth rib removed. A tumour was seen about the size of two fists. It was covered by large veins. The kidney was pushed down, but not adherent to it, and appeared to be normal. The tumour consisted of two parts closely in contact, but apparently not structurally joined. The more superficial part was first removed without much difficulty. The deeper situated portion, however, which was about the same size, was in contact with the arch of the diaphragm and closely adherent to surrounding parts. On completing

FIG. 2.



Naked-eye photograph of smaller tumour.

there was a considerable gush of venous blood from a vein torn off the inferior vena cava. It was also found that a small hole had been made in the right pleura. This was sutured.

Progress.

During the first few hours after operation her condition gave rise to some anxiety. The pulse-rate, which had been 104 before operation, rose to 132 and reached 148 during the next 24 hours. Temp., 101·5° F. Pituitrin was given repeatedly. The blood pressure on the day after operation had fallen to 120 systolic, rising to 130 after pituitrin. The condition remained somewhat critical during the first week. The temperature varied from 98·6° to 100°, the pulse-rate being 108 to 116. The systolic blood pressure was 130. The urine was rather above normal in amount and contained albumin. At the beginning of the second week there was a rise of temperature for three or four days. The pulse-rate again reached 148. After this the temperature fell to 98·6°–100° each day. The blood pressure remained steadily at 130 systolic.

About the end of the third week she had an attack of cystitis with frequency and pain. This subsided in a few

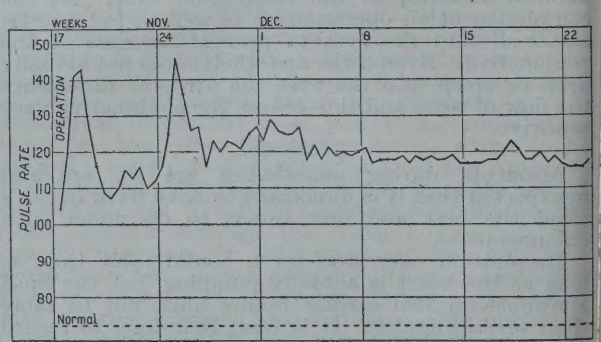


Chart showing pulse-rate after operation.

days, and after that improvement, though slow, was steady. The temperature became normal. Blood pressure, 125 systolic. The pulse, however, remained rather frequent—116–120. In the first week of January, 1927, she was able to return home. The pulse-rate had fallen to 100.

During the latter part of her stay in the nursing home definite changes occurred in the skin of the face. There was considerable exfoliation and scaling, and the hirsuties became less marked. The scalp hair began to grow again.

Pathological Report by Dr. HUMPHREY H. GLEAVE.

The specimen on removal was sent to the Pathological Department of Sheffield University, and the following report has been received from Dr. Humphrey Gleave, lecturer in pathology:—

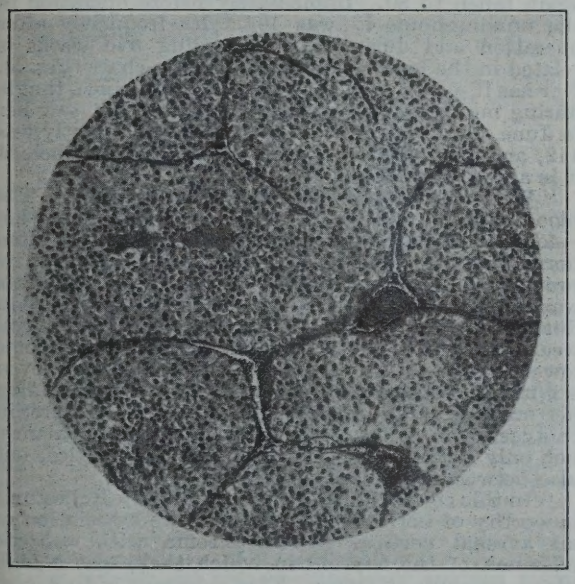
"The specimen received in Kaiserling solution on Nov. 18th, 1926, consists of two irregularly bossed masses of tissue, the larger (Fig. 1) measuring approximately 14·1 × 8·7 × 7·6 cm. and the smaller (Fig. 2) 12·1 × 7·3 × 6·9 cm. The former weighed in the wet state 464 g. and the latter 359 g. A portion of suprarenal gland was found adhering to one pole of the smaller mass. On section the two masses are found to consist of firm grey-white tumour tissue, divided irregularly by grey fibrous tissue strands, and showing numerous opaque yellowish patches of necrosis and areas of congestion.

"*Microscopical Examination.*—Large mass: the tumour consists of cells which are separated into columns and masses in a rather regular manner by capillary blood-vessels and sinusoids. The general arrangement resembles the zona fasciculata of the suprarenal, though the cell columns are frequently 10 or 20 cells in diameter. The blood-vessels separating the columns show a layer of endothelium supported by fine collagen fibres, with here and there a larger amount of fibrous tissue. A few collagen fibres also pass into the cell columns. The cells composing the tumour are fairly regular, polyhedral, measuring 13 to 24μ in diameter, with a large nucleus rich in chromatin occupying the greater part of the cell. The cytoplasm is finely granular, taking the pink eosin stain somewhat after the fashion of a liver cell. In numerous areas the cells contain clearer cytoplasm and vacuoles, but this appearance is probably due to degeneration, as it usually occurs at an area farthest away from a blood-vessel, and is sometimes accompanied by nuclear pyknosis. Multinucleated cells are scanty. Large areas of the growth show simple coagulative necrosis. There is very little hæmorrhage into the tissue. At the margin the tumour is bounded by a thick fibrous capsule, but in the midst of the capsule are seen a few groups of tumour cells.

"Smaller mass: Essentially the above description applies also to this tissue, but there are numerous areas in which the cells show more anaplasia. The trabecular arrangement is much less regular. There is considerable variation in the size and shape of the cells; in some areas they are oval. Multinucleated cells and hyperchromatic nuclei are fairly numerous. No chromaffin tissue could be demonstrated in either piece. Frozen sections of the formalin-fixed material were examined in polarised light. A small amount of lipoid is present in the tumour tissue, but practically none in comparison with the normal adrenal cortex.

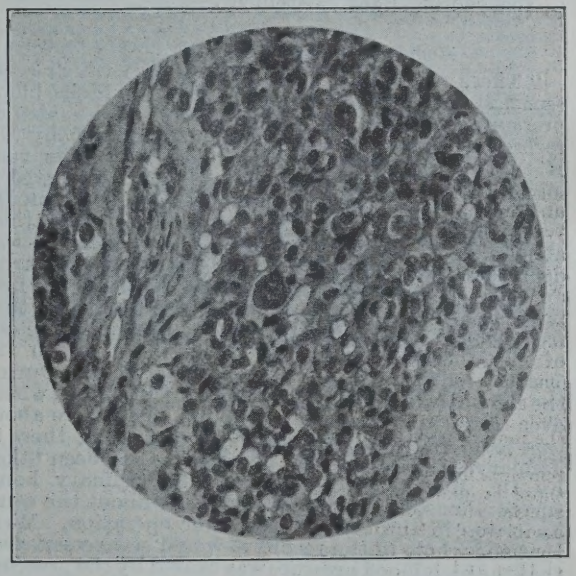
"The tumour is evidently an 'adrenal hypernephroma.'[5] Rolleston[6] suggests 'adrenal cortical hypernephroma' as the best designation for this well-recognised group of tumours. They arise from the cells of the adrenal cortex and are clearly distinguished from the paragangliomas and neuroblastomas arising from the medulla. Such tumours may be of all grades of malignancy. In Gordon Holmes's[1] case the symptoms dated from at least five years before the operation, and the patient was alive and well nine years later. The section showed a benign tumour (Prof. E. Glynn). In Glynn and Hewetson's[7] case there was amenorrhœa of 16 years' duration and hypertrichosis of four or five years' duration; the adrenal growth, weighing 12 lb., was encapsuled, and there were no secondary deposits. On the other hand, in Feinblatt's[8] case the total duration from the onset of pain followed by hypertrichosis to death was only eight months, and pieces of growth were present in the vena cava and right ventricle. There is also the possibility of a benign tumour becoming malignant, as seems probable in French's[6] case. The tumours which more closely resemble adrenal cortex are the more benign. Through the kindness of Prof. Glynn I have had an opportunity of comparing the sections from this case with those of five other cases of adrenal hypernephroma which he allowed me to examine. The sections show that the six tumours are all of the same variety. In histological detail the present case, although apparently more active, corresponds most closely with that in Glynn and Hewetson's[7] case. Though much of it has a benign aspect there are areas of cellular anaplasia with mitoses and multinucleated cells. The majority of adrenal hypernephromas show these features even when the tumours are still localised. According to Glynn,[5] in these tumours, on the whole, growth takes place more slowly than in most malignant tumours. The prognosis is therefore rather better than in most malignant tumours, as even those which appear histologically malignant may remain localised for a considerable time."

FIG. 3.



Low-power magnification of the large tumour mass (Fig. 1). Fairly regular cell columns are separated from each other by vascular sinuses and fibrous tissue.

FIG. 4.



High-power magnification shows an area of cellular anaplasia with much irregularity of cells and nuclei.

Further History of the Case.

Since leaving the nursing-home the patient has made steady though necessarily slow progress. Just before operation in November, 1926, she weighed 10 st. 5 lb., whilst in May, 1927, she only weighed 8 st. 3 lb. She says that during the months she was ill her appetite increased greatly, so that she was always longing for the next meal and never seemed satisfied. This has

entirely disappeared since the operation, and her appetite is now normal. She has begun to take an interest in her house and clothes, and although still somewhat lacking in energy feels much more like her former self. She drives her car alone. As regards her personal appearance the change is striking. The hirsuties has disappeared, the features have returned to what they were before the illness. The hair of the head has begun to grow again. The hands have returned to their previous dimensions, and there is a general return to the feminine softness which was quite lost before operation. It is unfortunate that no photograph of her condition at the height of the illness was obtained.

The menses reappeared in January and have recurred with perfect regularity ever since. An interesting point in connexion with this is that their recurrence was at exactly the time at which they would have occurred had she never missed a period. As was stated in the history of the case, the menses had always been absolutely punctual, the interval being exactly 28 days (four weeks). The last period, before they ceased, began on May 22nd, 1926, and their first reappearance was on Jan. 31st, 1927. A simple calculation will show that this date is exactly 36 weeks to the day from May 22nd. The pulse-rate remains slightly above normal, and the blood pressure, though, as a rule, only about 130, is still very easily raised to 190–200 on slight excitement.

Remarks by Prof. ARTHUR HALL.

"There are two features in this case which seem especially to call for comment—the high blood pressure and the frequent pulse. As the history records, the blood pressure, when first taken by Dr. H. W. Barber, early in November, 1926, was very high. For how long this high pressure had existed is unknown. It remained constantly about 200 mm. Hg systolic and 120 diastolic up to the time of operation, about a fortnight later. At that time also there was definite displacement of the cardiac impulse outwards, and this was of a heaving character. During the first few days after operation the patient was so ill that frequent investigations of the blood pressure were out of the question, but it fell on the first day to 120 systolic, rising to 130 after pituitrin was given. During the remainder of her stay in the nursing-home, whenever taken it was constantly found somewhere about this level—i.e., 130 systolic. Since leaving there in January, 1927, whenever the pressure has been taken by Dr. Murray amid the patient's ordinary home surroundings, it has been found to be about the same as it was in the early weeks after operation. Were that the whole of the record it would seem very clear that the high blood pressure was caused by the presence of the tumour alone. This view must, however, be somewhat modified. She was brought to see me in May, 1927, and I found that when, early in our interview, the pressure was taken, it was about 190 systolic. I waited until the end of the consultation so that any possible initial excitement might have settled down, and found that it was then much lower—about 140 systolic. It is evident, therefore, that although not constantly high it is easily raised, possibly by excitement.

"I saw her again on June 15th and proceeded in the same way. This time it was 170 systolic when she arrived, whilst at the close of the interview it was 200. She had driven her car a distance of three miles, but did not appear at all nervous or excited. The cardiac impulse was in the fifth left space in the nipple line and distinctly heaving.

"It is thus evident that whatever part the cortical hypernephroma may have played in bringing about the rise of blood pressure, this has not as yet returned to a steady normal level with the removal of the growth. Nor is it easy to see why a tumour apparently limited to cortical substance should have any effect in raising the blood pressure—a function of the medullary portion. So far as records of other similar cases go there is but scanty information as to blood pressure to help us. Some of these cases were published before the days of blood-pressure records. Amongst the more recent cases I cannot find any reference to blood pressure in Gordon Holmes's [1] case, either before or after operation; whilst in Feinblatt's [8] case, so far from being raised, it was below normal (110 systolic, 75 diastolic). In cases of adrenal medullary tumours a high blood pressure has been recorded, but by no means constantly. Many of the older records do not refer to the blood pressure at all, so that the number upon which to base an opinion is rather small. Rolleston [6] refers to one case in which a high blood pressure was definitely present, and mentions four other cases in which it was at least suggestive, but lacking in complete proof. On the other hand, Frew [2] records two cases in which it was not raised.

"Rolleston [6] sums up the situation as follows: 'The interesting question whether or not tumours of the medulla often provide an excess of normal or altered adrenin cannot yet be regarded as settled . . . there is not sufficient evidence to justify the tempting conclusion that hyperadrenalism analogous to hyperthyroidism exists.' On the other hand, in the present case, there has been also a change in the pulse frequency. She is quite sure that prior to this illness her pulse was always about 80 per minute. In November, 1926, however, before taking to bed, it was 110. After two weeks in bed, before operation, it had again fallen to 80. Immediately before operation in the nursing-home it was 104. Its frequency after operation and during the succeeding five weeks is related in the history and shown in the chart (Fig. 5). Nor has it ever returned to a normal rate since, that is during more than six months. When I last saw her in June, 1927, the pulse-rate when sitting quietly was 112, and she tells me that when she takes it herself it is always 100 to 106.

"We have, therefore, these two sets of facts: The blood pressure was very high shortly before operation—fell to normal immediately after operation—is often normal now, six months later, but easily goes up to its previous height from trivial causes. The pulse-rate was normal before her illness—was raised to 100–110 during her illness—was still further raised for several weeks after the operation, and has not yet become lower than it was in the weeks before operation, even six months afterwards, although she is now leading her ordinary life. It seems as though there were, in this case, some gross disturbance of endocrine balance, not only between the adrenals and the ovaries, but also between the adrenals and the thyroid.

"In this connexion a case referred to by Rolleston [6] is worthy of notice. He mentions the association of an adrenal cortical hypernephroma with a toxic adenoma of the thyroid in which there was a high blood pressure at times. This reference is to a case recorded by Keyser and Walters [3]:—

> A woman, aged 37, the mother of ten children, has not menstruated since the last pregnancy ten years before. For two years she had noticed an enlargement of the thyroid gland, together with some nervousness, occasional tremor, and some palpitation. There was also increased sweating and dyspnœa on slight exertion. Her appetite increased and she had put on 30 lb. in weight, but in spite of this became weaker. For 18 months some changes had been noticed in the skin, and considerable hypertrichosis of the face was present, so that she had to shave. The trunk and limbs were also affected. A diffuse alopecia of the scalp was present. Some albumin and sugar were found in the urine. For a year there had been aching in the back. When seen in February, 1923, there was an adenoma in the thyroid and a large rounded swelling on the left side of the abdomen under the costal margin. This was removed on Feb. 28th and found to be a 'malignant suprarenal hypernephroma.'

"The patient only survived operation four days. In this case before operation the blood pressure varied from 124 to 180 systolic, and from 90 to 110 diastolic, whilst the pulse-rate varied from 100 to 130. After operation the pulse-rate increased in frequency and the systolic blood pressure is described as being 'low and indeterminate' up to the end.

"Although the present case, unlike that of Keyser and Walters, has no obvious change in the thyroid

gland, yet as regards blood pressure and pulse-rate there is a certain resemblance between the two cases. Possibly the persistence of the pulse frequency at the level about the same as before operation, and the tendency to a rise of blood pressure on slight disturbance, may mean that there are some further remains of hypernephromatous tissue still present, insufficient to cause a constant high blood pressure, but enough to keep up the thyroid over-activity."

In recording this case the authors' thanks are due to Dr. H. W. Barber for first diagnosing the condition, to Dr. H. H. Gleave for the pathological report and microphotographs, and to Prof. Arthur Hall, for much assistance and advice throughout.

A CASE OF
SUPRARENAL HYPERNEPHROMA.

BY C. M. KENNEDY, M.B.E., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH;
AND
W. A. LISTER, M.B. CAMB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE HOSPITAL.

SINCE Bulloch and Sequeira (1905) published their classical paper this remarkable condition has become widely recognised. It is hoped, however, that the following case will prove of sufficient interest to warrant its being placed on record.

History.

A girl, aged 13½, was admitted to the South Devon and East Cornwall Hospital on June 24th, 1927. Her mother stated that, though she had always been a plump girl, obesity had been increasing rapidly during the last six months. In February, 1927, she had fallen off a bench at school and hurt her back. Since that time she had complained of pain in the back and slowly progressing weakness of the legs, so that in June she could only get about with great difficulty. During the same period the external genitals had rapidly increased in size, but menstruation had not begun. In other respects she was a healthy child and had made satisfactory progress at school. At no time had she suffered any severe illness.

The patient was the second of four children born to the mother's second husband, who died of tuberculosis of the lungs. The other three children were alive and well. The mother's first husband was killed in an accident and her two sons by him died at about 24 years of age, one of fever in Canada and the other of (?) epilepsy.

Clinical Examination.

On examination the patient presented a remarkable appearance. She was 4 ft. 6 in. in height and weighed 6 st. 12 lb. Her face was that of a stout little old woman with very high colour and a scanty growth of fine black hair on the upper lip. The thyroid gland was not palpable and the hands and fingers were fine and tapering. Over the neck, trunk, and buttocks the subcutaneous fat was greatly increased, but no supraclavicular pads were present. The skin, which was not abnormally dry, showed a slight general pigmentation and numerous purple striæ atrophicæ over the hips, buttocks, and lower abdomen. Over the shoulders and down the back was a moderately thick growth of black hair up to one inch in length and most abundant in the interscapular region. The pubic hair was much in excess of the normal for the patient's age and presented a horizontal upper margin. The labiæ also were abnormally developed, but the clitoris was not hypertrophied to a disproportionate degree.

As compared with the trunk the limbs appeared rather thin, though in fact there was a normal amount of subcutaneous fat present. Both quadriceps extensor muscles were slightly wasted and there was weakness of extension of the knees. Both knee-jerks were absent. Movements of the ankles were strong, the ankle-jerks were present, and the plantar responses flexor in type. The abdominal reflexes were present, but rather sluggish in the lower segments. No loss of sensation of any type could be detected, nor was any other abnormality found in the central nervous system. The heart and lungs were free from signs of disease. In the left hypochondrium an irregularly rounded tumour the size of a fœtal head could be palpated, passing back into the loin and upward beneath the costal margin, but not in close apposition to it. The mass did not seem to be firmly fixed, and it moved slightly on respiration. On percussion a resonant note was obtained over the tumour. The liver and spleen were not palpable and nothing abnormal was felt per rectum.

FIG. 1.

Back and front view of patient, showing alteration in figure and facies.

The temperature was normal and the pulse-rate varied between 80 and 100. On admission a trace of sugar was said to have been found in the urine, but this was never detected on subsequent occasions, nor was any other abnormality found in it. On June 24th a blood-count gave the following results: red cells, 5,100,000; hæmoglobin, 88 per cent.; total leucocytes, 14,800, of which 67 per cent. were neutrophils and 33 per cent. lymphocytes.

A diagnosis of tumour of the left suprarenal cortex was made, but it was feared that the absence of knee-jerks and weakness of the quadriceps extensor muscles was due to metastases involving the lumbar plexus. However, a radiogram showed no signs of disease of the spine and a film of the chest showed no metastases in this position. The question of operation for removal of the tumour therefore arose, but a perusal of the literature was not encouraging. Records of only four cases of successful removal of such tumours could be found—namely, those of Knowsley Thornton, Collett, and Bovin (quoted by Gordon Holmes, 1924) and except for Collett's case these were in much older patients. In THE LANCET of July 9th there was a note that another successful case had been reported at a meeting of the Pathological Society of Great Britain on July 1st by Gleave and Wilson, the patient being a woman of 36 years.*

As the prognosis without operation was hopeless it was decided that the risk was justifiable, and on

* This is the case described by Dr. Murray and Mr. Simpson in our present issue.—ED. L.

July 12th the tumour was removed through a left lumbar incision under general anæsthesia. It was found to be covered by a thin fibrous capsule and was easily separated from the surrounding structures except at one point on its postero-internal aspect, where the capsule was deficient and the tumour somewhat adherent. On inspecting the cavity from which the tumour had been removed its relationship to the left kidney, spleen, pancreas, and colon were clearly demonstrated. Few vessels required ligature and none of these were of any size. The patient stood the operation well and her condition remained good for ten hours. Her pulse then suddenly became very rapid and weak and she died 36 hours after the operation.

At *autopsy* there was found to be moderate bruising and slight extravasation of blood into the left half of the pancreas, lower half of the spleen, upper pole of the left kidney, and the cellular tissue around the solar plexus. No sign of the left

FIG. 2.

Section of hypernephroma. (× 30.)

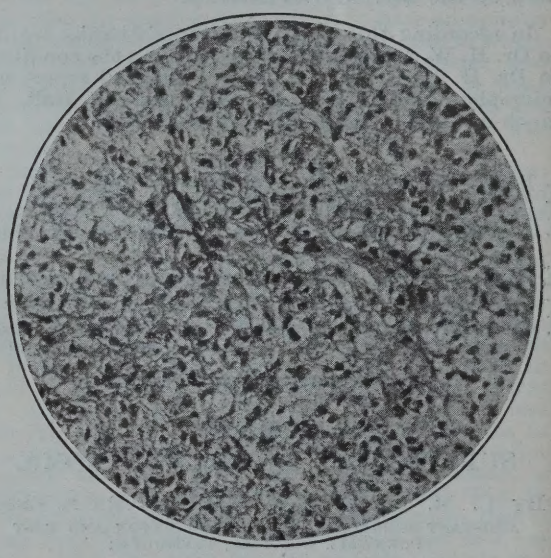
adrenal body or of any tumour substance in the neighbourhood was found. The right adrenal body was only found with some difficulty. It measured 2·5 × 1·5 × 0·2 cm. On section the cortex was represented by a row of pinhead yellow nodules and the medulla by a small amount of grey material. The uterus was infantile and measured 4·3 cm. in length and the ovaries were smooth, firm, yellow bodies measuring 1·25 × 0·5 cm. with no superficial follicles or signs of activity. In the apex of the right lower lobe of the lung beneath the visceral pleura was a metastasis from the tumour the size of a pea. No other metastasis was found. The kidneys, liver, and myocardium showed slight parenchymatous degeneration and the lungs were œdematous and congested at the bases. It was not possible to examine the central nervous system and no cause for the absence of knee-jerks was found. The lumbar plexus was normal on both sides.

The tumour measured $8\frac{1}{2} \times 5 \times 2\frac{3}{4}$ in., weighed 3 lb. 13 oz., and was roughly kidney-shaped. Its colour was grey, and except at one point where the covering was deficient it was surrounded by a thin capsule in which ran numerous small blood-vessels. The surface was lobular. On section the tumour was seen to be composed of a number of rounded masses equalling a large walnut in size and mottled grey and yellow in colour. It was freely supplied with blood from vessels running in loose fibrous septa arising from the capsule and separating the individual tumour masses from one another. At no point was any sign of degeneration to be seen.

Microscopically the tumour was seen to be composed of polygonal cells varying in size, but the majority very large. They presented a well-defined cell outline and very vacuolated, foamy, or spongy protoplasm, and round or oval deeply-stained nuclei. These cells were divided into groups of varying size by thin fibrous septa containing very thin-walled blood-vessels. There were also a few larger vessels with muscular walls in the sections. Multinucleated giant cells were few.

The secondary deposit in the lung presented a well-defined border. The tumour cells resembled those of the primary growth, but were not so vacuolated, and numerous multinucleated giant cells were present. The cells were divided into groups of uniform size by very delicate fibrous septa containing thin-walled blood-vessels distended with blood. The right suprarenal body showed all the normal types of

FIG. 3.



Section of hypernephroma. (× 200.)

cell found in this organ, but the columnar arrangement in the cortex was indistinct and irregular. The ovary showed a stroma rich in spindle-cells containing very numerous Graafian follicles each of which consisted of an ovum enclosed in a theca of a single row of cells. The section also showed a larger follicle with a multicellular theca and a very large cystic follicle with discus proligerus.

Summaries of the literature relating to this condition have been made by Bulloch and Sequeira, Glynn, and

FIG. 4.

Cortex of right adrenal gland. (× 30.)

Gordon Holmes, and there is no need to recapitulat them here. It may, however, be pointed out that i cases of this type the opposite suprarenal not uncom monly appears to be poorly developed. This was s in the present case, and in that published by Hijman (1915), in which the patient died shortly afte operation, the opposite suprarenal was describe

as very pale, pale yellow, and narrow (zeer bleek, bleek-geel, smal). Again, Glynn and Fordyce exhibited a similar case in a boy aged 2 in which the opposite suprarenal was atrophied at the meeting of the Pathological Society already referred to.

A SMALL OUTBREAK OF ERYTHEMA NODOSUM.

BY MAURICE MITMAN, M.B., M.R.C.P. LOND.,
CLINICAL ASSISTANT, ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, LONDON.

Erythema nodosum is once more attracting attention, and there prevails again a tendency to isolate it as a disease sui generis and to relabel it, as did Lendon, "nodal fever." [1] Accounts of definite outbreaks suggesting the specific infectious character of the condition are not abundant, and I therefore record this small epidemic.

The five cases here related occurred almost simultaneously; all were drawn from the same London district, and all were detained in St. Marylebone Hospital at almost the same time. In the first two cases there is evidence of direct contact. The outbreak occurred during the prevalence of an epidemic of so-called influenza in the early months of this year. In every case except one the condition was, in the first instance, diagnosed as acute tonsillitis if a gross throat lesion were present, or as influenza if the throat appeared normal.

CASE 1.—Male, aged 50, of the resident medical staff, St. Marylebone Hospital. Susceptible to attacks of tonsillitis and influenza whenever these were prevalent; otherwise healthy. No history of rheumatism or tuberculosis. Jan. 9th, 1927: Febrile attack; temperature 100° F.; generalised pains; throat normal; heart normal; diagnosed as influenza; confined to bed three days. 14th: Pains in legs, especially in ankles; developed typical medium-sized lesions of erythema nodosum confined to the legs. Condition subsided in a week. Some general debility followed.

CASE 2.—A probationer nurse at St. Marylebone Hospital, aged 24. Subject to attacks of acute tonsillitis. No history of rheumatism or tuberculosis. Jan. 21st: Severe attack of acute tonsillitis with generalised pains in back and limbs; temperature 100° F.; tonsils enlarged and septic with injection and follicular spots; glands of neck enlarged and tender. 29th: Developed a typical severe attack of erythema nodosum; nodules of medium size appeared at intervals, were confined to legs, and were associated with severe pain in the lower extremities, particularly in knees and ankles. By Feb. 11th all lesions had cleared up. Considerable debility followed. Tonsillectomy was performed later.

CASE 3.—A woman, aged 48. Frequent inmate of the hospital, suffering from a mild degree of hyperthyroidism. No history of rheumatism or tuberculosis. Jan. 18th: "Influenza," malaise, and general aching, particularly of back and limbs; mild sore-throat. 25th: Pains in legs; swellings appeared. Feb. 2nd: Admitted to hospital; had typical lesions of erythema nodosum confined to front of legs; nodules of varying sizes and in different stages; some yellow nodules in process of subsidence; others fresh, red, and tender; still complained of pain in joints and fascial planes; temperature normal; heart normal except for slight tachycardia; pulse-rate 90; throat normal. 22nd: Clear.

CASE 4.—Boy, aged 6. History rather indefinite, but said to have been ill about ten days. Jan. 31st: Sent to hospital as erythema nodosum; typical mild attack; few nodules in process of subsidence; pain slight; temperature normal; throat normal. Feb. 8th: Clear.

CASE 5.—Woman, aged 29. No history of rheumatism or tuberculosis. Jan. 26th: "Influenza," headache, generalised pains, and later sore-throat. Feb. 6th: Developed pain and swellings on legs. 8th: Pain in chest on breathing. 9th: Sent to hospital as tonsillitis and ? pleurisy; temperature 103° F.; no definite physical signs in chest but picture suggestive of pleural pain, thought to be possibly diaphragmatic; also pain in neck. On the legs were typical lesions of erythema nodosum; a few large nodules and multiple small ones. Fresh lesions appeared during the next five days. 16th: Temperature normal. 28th: Erythema nodosum cleared up; simultaneously pain in neck and chest disappeared.

I would add that I have the authority of my colleagues that there were two other cases of erythema nodosum in the hospital at this time under their care. Unfortunately, I have been unable to trace the case-records of these.

For contrast I describe below two sporadic cases of nodose eruptions suggestive of erythema nodosum but which I prefer to classify as erythema multiforme, and from consideration of these, and by analogy with two pulmonary conditions, to offer a suggestion which explains the apparent relationship between these two dermatological conditions.

CASE 6.—Probationer nurse, aged 25. Anæmic; never robust; in early part of 1927 had tonsillitis, and later perforated appendix; no history of rheumatism or tuberculosis. May 19th, 1927: Following general malaise, developed multiple, red, tender, subcutaneous nodules on anterior surfaces of both legs; diagnosed as erythema nodosum. June 2nd: Bullous lesions appeared. 23rd: Fresh crop of lesions, some pustular, still confined to legs. August 7th: Practically clear.

CASE 7.—Woman, aged 47. Said to be subject to rheumatism, although the type of pain described was not clearly of the variety met with in true rheumatism. January, 1927: Delivered of an infant which she fed on the breast. April: Developed right mastitis. May 1st: General malaise and discharge from the right nipple; some days later an abscess in the right breast ruptured spontaneously through the skin. 9th: Pains in joints and tender swellings on arms. 16th: Admitted to hospital, with temperature 103° F., for large abscess of right breast; had an eruption, mainly along subcutaneous borders of ulnæ, of moderate-sized, tender, red nodules, apparently a typical eruption of erythema nodosum. 17th: Breast abscess incised. 19th: Developed a crop of small papules on the hands and forearms. Then the advisability of rediagnosing the condition as erythema multiforme arose. 23rd: Papules disappeared, but a nodule appeared on one leg. June 4th: Recurrent pyrexia and pains in legs with fresh crop of nodules on shins, again very like erythema nodosum. Lesions on arms subsided by passing through typical discoloration stage. 25th: All lesions cleared up and breast practically healed.

In Case 6 it is quite clear that the original nodular lesions were merely a phase and a variety of the eruption of erythema multiforme. The close resemblance to erythema nodosum was soon dispelled with the appearance of the subsequent lesions. In the latter case, however, the resemblance was even closer. Except for the four days when the papular eruption was manifest the case was absolutely indistinguishable from erythema nodosum. Even now I am not convinced that this was not the true diagnosis. The following analogy, however, will perhaps illustrate what I conceive to be the differences between erythema nodosum and multiforme, and why I consider that Case 6 can be separated at once from erythema nodosum, whereas Case 7, whilst very suggestive of erythema nodosum, can be regarded as a variety of erythema multiforme. For the purposes of my analogy I use the characteristics of the two conditions, lobar pneumonia and broncho-pneumonia.

Typical lobar pneumonia is a definite clinical entity, an acute specific infectious disease of known ætiology and abrupt onset. Sporadic cases and epidemics are known. It produces characteristic physical signs (of consolidation limited to one area of the lung). Its tendency is to clear up entirely and recurrences are not common. Broncho-pneumonia (secondary) is, however, an entirely different condition, of mixed ætiology and varied manifestations. Its onset is often insidious but may be abrupt. Its physical signs are many and varied but may be typical, and in a straightforward case confusion with lobar pneumonia is unlikely. It tends to be pro-

[1] G. F. Walker: The Place of Erythema Nodosum in Medicine, British Journal of Dermatology and Syphilis, June, 1927, p. 241 (with bibliography).

tracted and recurrences are common. Nevertheless, atypical cases are frequent, and one type, owing to its close similarity to lobar pneumonia, is labelled the pseudo-lobar form. In this a confluent patch of broncho-pneumonia may be the only clinical manifestation and the differentiation from lobar pneumonia extremely difficult.

In the analogy I wish to draw erythema nodosum can be aptly compared with lobar pneumonia. Practically all that has been said of the one can be applied to the other. Similarly, erythema multiforme can be considered analogous to broncho-pneumonia. In its typical manifestation erythema multiforme is quite distinct from the condition which has been labelled nodal fever, but the unusual nodose type of erythema multiforme may bear a striking resemblance to erythema nodosum. Case 6 illustrates this point very well, but the similarity was short-lived. Having, then, admitted the possibility, it is easy to accept Case 7 as a similar example in which the transient papular eruption supplied the clue to the problem.

I wish to acknowledge my indebtedness to Mr. B. Hood, medical superintendent of St. Marylebone Hospital, for his permission to publish these cases.

A CASE OF HYPERTROPHIC LEUCOPLAKIA OF THE TONGUE

TREATED BY SOUTTAR'S CAUTERY.

BY HENRY C. SEMON, M.D. OXF., M.R.C.P. LOND.,
PHYSICIAN FOR DISEASES OF THE SKIN, AND MEDICAL OFFICER IN CHARGE OF THE VENEREAL DEPARTMENT, ROYAL NORTHERN HOSPITAL, LONDON.

THE possible developments of intractable leucoplakia of the tongue, to which the classical work and publications of Butlin [1] first drew general attention, are now fully realised and justly feared. Many of the early cases yield to antisyphilitic treatment and elimination of oral sepsis and irritation—as from excessive smoking—but it will be admitted that occasionally these measures seem powerless to cure, or even arrest, the progress of the disease. The textbooks are very pessimistic. Prof. R. L. Sutton states [2] that ". . . . it is exceedingly rebellious to treatment, and many cases are practically incurable. The possibility of cancerous involvement should always to borne in mind." R. W. MacKenna [3] likewise describes it as ". . . . very rebellious to treatment, and prone to become cancerous"; and David Lees [4] is equally emphatic, remarking that "it is peculiarly resistant to treatment and is often the precursor of malignant disease." Many similar quotations might be given, but there are probably no disputants of Butlin's original thesis, and we are free to inquire what remedies are available when anti-syphilitic drugs and dental ministrations have failed us. Sutton [2] gives a long list. It includes mild astringent and alkaline mouth washes, pencilling with silver nitrate, methylene blue, resorcin (Unna), 20 per cent. solution of chromic acid, pure acid nitrate of mercury (Sherwell), and the actual cautery (Stellwagon). Carbon dioxide snow, in spite of the risk of reactive swelling, has its advocates, and during the past ten years X rays and radium have been employed with good results and occasional cure in mild cases.

Most authorities would agree with MacLeod,[5] who maintains that ". . . . caustic remedies or the actual cautery should be used with the utmost caution for fear of producing malignant changes, and on the whole are better avoided." With this view I am in entire accord, for the reason that none of them go far enough. They may fairly be described as *half measures* in that they do not aim at removing the whole of the actively growing and irritated area. None of us would contemplate their employment for lingual cancer; why, then, have they been advocated and used for a condition which may, and not infrequently does, proceed to that state? It seems strange that with so serious a prognosis surgeons do not come forward more frequently with the suggestion of dissection or plastic ablation of the diseased mucous membrane in resistant cases. The fact is that such cases are allowed to drift, and the ultimate fate of some of them is a sad commentary on modern therapeutics.

It was the very chronic and intractable case I am about to report that first turned my attention to the possibility of radical destruction or extirpation of such areas, but it was not until Mr. H. S. Souttar had perfected his steam-heated cautery [6] that I believed myself in a position adequately to effect this. I might, it is true, have availed myself of diathermy, of which I had had some previous experience in cases of rodent ulcer and lupus vulgaris; but I had discovered for myself that its action as regards penetration, which probably depends on variations of electrical conductivity, is most unreliable and difficult to assess and control, and I considered that for a relatively superficial condition it was not an ideal implement. A deep burn in a muscular and highly mobile and sensitive organ like the tongue might lead to deformity or a most irksome fixation, and then again there was the possible if remote risk of igniting the anæsthetic gases by accidental sparking during the operation. Mr. Souttar's simple device, which has not yet received the recognition it undoubtedly deserves, is free from all these objections and dangers, and I have used it repeatedly in cases of rodent ulcer on the nose and in close proximity to the upper air passages.[7]

The subject of this report is a stout, healthy looking widow of 55. She contracted syphilis in 1904, and was treated for 18 months according to the best regimé then available at St. Bartholomew's Hospital. About seven years before she attended at the Royal Northern Hospital she began to suffer from a sore tongue, and for a further seven years she most patiently attended our venereal department where, in spite of vigorous and repeated courses of novarsenobenzol, silver salvarsan, mercury, bismuth, and iodides, the extraction of all her teeth, and the local application of all the accepted remedies, including X rays, the lingual condition remained *in statu quo ante*, and the strongly positive Wassermann reaction could not be shaken. In July, 1924, I noted that the dorsum of the organ was smooth, shiny and entirely destitute of the normal papillæ, and about the centre there was a roughly quadrilateral patch of hypertrophic sodden epithelium which closely resembled a fragment of adherent wet chamois leather three-quarters of an inch across at its greatest dimension. It was evident that this patch was the source of her symptoms, and in April of this year I considered that its destruction by means of Souttar's cautery was not only feasible but offered a good chance of cure. On May 28th she was admitted to the wards, and on May 31st, under a general anæsthetic (intratracheal ether), a stitch was passed through the muscle and the organ drawn forward. After thorough drying with gauze the whole of the affected area (and a little beyond) was coagulated with a suitable steam-heated applicator. The resulting débris was easily scraped away with a sharp spoon. The slight oozing was controlled at once by another application of the cautery, and to make certain that a sufficient depth had been reached the procedure was repeated a second time until the surface of the underlying muscle was exposed. The dry eschar was coated with a thin layer of Whitehead's varnish, and the patient sent back to the ward. No pain was felt on recovery from the anæsthetic, nor was this complained of until some five days later, when the slough separated and left a raw, tender surface which caused a good deal of trouble during the following week. Healing was complete when the patient was seen on July 8th. The white patch had been completely replaced by the shiny smooth surface common to the rest of the tongue, and there was no sign of contraction. The patient stated she had lost all her discomfort and was able to masticate freely and taste all her food.

The symptoms described under the heading of "Smooth Tongue" in Butlin's admirable book (pp. 141–43) are not present in this case, and it must not be forgotten that in his day the important element of dental sepsis was hardly considered in its relation to diseases of the tongue.

It is obvious that success in a single case cannot justify the drawing of broad conclusions, but I am hopeful that in a certain type of chronic and intractable papillomatous overgrowth the method will be found of considerable value. The technique is very simple

and with good anæsthesia should not give rise to difficulty. The local application of anæsthesin, which was not tried in this instance, may help future patients over the period when separation of the slough gives rise to pain.

Summary.

A chronic resistant patch of hypertrophic leucoplakia lingualis of syphilitic origin was submitted to coagulation by Souttar's steam-heated cautery with satisfactory results. The method is simple and offers no special difficulties. It should find a considerable field of usefulness in cases with demarcated hypertrophic patches and fissuring, but it is not suggested that it should be used until the recognised methods have received a thorough trial.

TREATMENT OF POST-PARTUM HÆMORRHAGE.

BY JOHN SOPHIAN, M.R.C.P. LOND.,
MATERNITY AND CHILD WELFARE OFFICER, BOROUGH OF GREENWICH.

HÆMORRHAGE occurring after the birth of the child may have its origin at the placental site or at any other area in the genital tract where a breach in continuity of the surface has opened up the subjacent blood-vessels. It is helpful to determine from which source the bleeding occurs, and as a working rule it may be said that if bleeding is continuous and without relation to the state of contraction of the uterus a laceration is the cause.

Unless the torn surface is discovered the preliminary stages of the treatment must be identical with those of post-partum bleeding from the placental site, to be described later. Marked post-partum bleeding most often has its origin at the placental site. The retention of the partially separated placenta in the uterine cavity prevents the uterine muscle from exercising its full retractile effect on the gaping sinuses. The treatment of this bleeding is the main subject of the present article.

Ætiology.

Insufficiency of the uterine contractions may be due to various causes. The contractions of the third stage may in themselves be feeble and primary uterine inertia in the first stage of labour would presage this. Second stage pains are largely voluntary. The uterus contracts and causes a descent of the child on to the levator ani and the perineum; the reflex stretching of these structures provokes an expulsive effort of the abdominal musculature. Quite a small stimulus—in other words, a weak uterine contraction—might provoke a large voluntary expulsive effort, and it therefore comes about that the visible efficiency of the second stage is not a true criterion of the functioning of the uterus itself. Or the uterine contractions may be sufficiently strong and yet abnormality in the mechanism of placental separation may hinder the process. A further factor responsible for hæmorrhage is too early resort to Crede's expulsion. If the placenta is separating by the mechanism of retroplacental hæmatoma formation (Schultze's method) each succeeding uterine contraction is producing a uniform tension on the imprisoned blood, causing it to move centrifugally and force itself uniformly into the periphery of the area still attached. At the same time there is a shortening of the uterine muscle-fibres which further assists uniform separation. Obvious bleeding, consequent on this separation, occurs mainly after expulsion of the placenta. Premature attempts at Crede's expulsion may cause the retroplacental hæmatoma to find an outlet at one point, thereby destroying the mechanism, and since the placenta is still attached to its site by a large part of its circumference an obstacle is created to its further separation, which will then follow on the lines outlined by Duncan. It is possible also that undue stimulation of the uterus by vigorous kneading and by attempts at Crede's expulsion cause the lower segment of the uterus to retract down and interfere with placental delivery. These causes of failure to expel the partially separated placenta prevent complete retraction of the muscle-fibres and the consequent occlusion of the placental sinuses.

Prophylaxis.

It is important to counteract these ætiological factors. In the first stage primary inertia is overcome by resting and reassuring the patient, treating sleeplessness, and by quinine in ordinary therapeutic doses. In the second stage delivery must not be assisted in the presence of secondary inertia; the child should be delivered slowly and during a uterine contraction. The hand should be on the fundus throughout the whole of this process. In the third stage premature attempts at expulsion of the placenta must be rigorously avoided though the uterus should be supported and gently massaged, if necessary, to overcome flabbiness and to prevent the cavity filling up with blood. It is as well also to anticipate post-partum hæmorrhage in cases where there is a family or individual predisposition to it, and also where uterine inertia might be threatened by multiple pregnancy, hydramnios, or antepartum hæmorrhage.

Treatment.

When the placenta separates by Duncan's method bleeding occurs freely during the process, whereas in Schultze's mechanism most of the bleeding occurs afterwards. Loss of more than 15 to 20 oz. may arbitrarily be taken to constitute post-partum hæmorrhage. It is assumed that until this amount has been lost the uterus has been supported in the hollow of the hand and any flabbiness counteracted by gentle massage. If in spite of this hæmorrhage tends to pass these arbitrary limits, treatment must become active. It is well, before conducting the third stage of any labour, to have in readiness a pair of boiled rubber gloves and a syringe charged with 1 c.cm. of pituitary extract of a brand containing a minimum of foreign protein. If the hæmorrhage, although excessive, is not of immediate urgency the hands and forearms should be re-sterilised as efficiently as possible while an assistant controls the uterus. The accoucheur then supports the fundus in the hollow of the left hand while the patient lies on her back with the buttocks at the edge of the bed. The assistant bathes the vulva with water at a temperature of 120° F., a proceeding which stimulates the uterus to contract and at the same time helps to cleanse the parts. Then the uterus is rubbed up, and at the height of its contraction a forcible attempt at Crede's expulsion is made. If this fails 0·5 c.cm. of pituitary extract should be injected intramuscularly by the assistant. The next contraction is awaited and expulsion then attempted again.

Primipara; delivery at full term; hæmorrhage commenced freely after 20 minutes of placental separation, loss approximately 1 pint. Patient's condition good. Crede's expulsion failed. Pituitrin 0·5 c.cm. was injected and at height of contraction the placenta was expressed. No further loss.

If failure attends this second attempt the finest judgment is called for in deciding how long to temporise before invading the uterus. There is risk of losing the patient through continued hæmorrhage, but invasion of the uterus is attended in a certain number of cases with fatal sepsis. If removal can be performed with strict asepsis, as at a lying-in institution, the danger of infection is small and invasion should not be unduly postponed. If the home conditions and the personal hygiene of the patient are satisfactory the risks are

slightly greater, but it would be safer to err on the side of early placental removal than to expose the patient to further hæmorrhage. In proportion to the unsuitability of the surroundings the difficulty of maintaining asepsis increases, but notwithstanding this no patient should be permitted to drift into a stage where life is endangered. If the bleeding is in large gushes and the loss is rapidly mounting up to the 30 oz. mark, there is no alternative but immediate evacuation.

Primipara; forceps delivery at full term; prolonged second stage. Ten minutes after delivery bleeding was profuse and loss continuous. The uterus was not responsive. Crede's expulsion during contraction failed; 1 c.cm. of pituitrin a few minutes later was followed by an unsuccessful attempt at expulsion. Loss approaching 30 oz. without any indication of ceasing. Manual removal of placenta. 100 c.cm. of antistreptococcal serum injected in two days. Highest puerperal temperature 100° for one morning only.

If the bleeding has reached a pint and the patient shows signs of collapse, removal should not be delayed. Most women, however, will not be seriously affected by a loss of this amount. In some cases an injection of 0·5 c.cm. of pituitary extract is sufficient to cause temporary faintness shortly after the dose has been administered, and allowances must be made for this. If the bleeding has reached a pint and a half, the patient does not appear dangerously affected, and yet there are no signs of rapid birth of the placenta, it is as well to invade the uterus since further loss will certainly accompany separation and added bleeding might intervene.

Primipara; normal delivery; second stage of two hours. Profuse and immediate loss of 30 oz. Manual removal of placenta forthwith. Antistreptococcal serum injected (40 c.cm. in all). No raised temperature throughout puerperium. Involution normal.

Multipara; normal delivery; short second stage. An hour and a half after delivery the patient was losing very gradually, in all about 30 oz. Pituitrin 0·5 c.cm. injected. Expulsion not successful but the loss was much diminished. The placenta eventually needed manual removal. The patient's condition was fair throughout. Antistreptococcal serum, 80 c.cm. in all, was injected. There was no raised temperature throughout the puerperium.

If the bleeding has ceased it is a moot point whether a patient who has lost 30 oz. of blood and is shocked in consequence should be left to recover from this shock before evacuation. Occasionally a period of recovery may be allowed, but it should be as brief as possible, *and the accoucheur should certainly not leave the patient meanwhile.* His hand should be kept on the fundus uteri, especially if the foot of the bed has been raised, because any blood lost, instead of revealing itself by gravitating towards the cervix, is retained and tends gradually to fill the uterus, especially as the muscular tone has been diminished.

The best way of estimating blood loss is by careful collection in receivers of known size. The figures given allow for the defects of this method.

Removal of the Placenta.

The following technique should be carried out. The extravaginal part of the cord and the skin around is painted over with iodine. The left hand supports the uterus, the thumb being in front and the fingers behind; the gloved right hand, which has been kept sterile, is carefully introduced through the vulva into the vagina and is *not* withdrawn until the placenta is brought away with it. The cord is the best guide into the cavity of the uterus and the fingers follow its length until the placenta itself is reached. The uterine surface of the membranes is sought and separation commenced by a sawing movement. The external hand prevents the fundus from rising, thereby facilitating the manipulations of the internal hand. At this stage bleeding may be profuse, but the separation must be carried out deliberately and without any flurry. Sometimes difficulty is experienced with the last attached portion because it is the most inaccessible and because the hand becomes cramped. If this attached portion is a small one gentle traction on the mass of the placenta is permissible and will almost always effect separation This is better than withdrawing and reinserting the hand. With the external hand the uterus is stimulated to contract and the internal hand is expelled with the placenta in its grasp. When the placenta is removed and bleeding persists, bimanual compression should be practised. Pressure is applied by the internal hand through the anterior fornix, the external hand meanwhile anteverting and pressing the body of the uterus downwards. In this way the placental site is compressed and bleeding temporarily checked. The remaining 0·5 c.cm. pituitrin is injected intramuscularly at this stage. If these means are insufficient bimanual compression should be maintained till a douche of at least six pints at a temperature of 118° F. is available. A drachm of iodine or lysol is added to each pint. The cervix is drawn down to the vulva and an intra-uterine nozzle is inserted as far as the fundus. Irrigation is continued till bleeding ceases. The patient is promptly treated for hæmorrhage in the routine way. An injection of gr. ¼ of morphia is administered and 1 c.cm. of aseptic ergot is given intramuscularly and followed up with drachm doses of ergot four-hourly by the mouth. Where feasible blood transfusion should be tried whenever the hæmorrhage has threatened life. In spite of aseptic precautions antistreptococcal serum should be given about 20 c.cm. each day for five days. As soon as the patient's condition permits, she should be propped up in bed so that any exudate gravitates into the pelvis. It is always advisable, after hæmorrhage of any severity, or in any delivery where atony of the uterus is suspected, for the patient to be watched for six to eight hours for concealed bleeding, especially when the foot of the bed is raised.

Multipara; forceps delivery; placenta normally born but accompanied with a loss of about 30 oz. Patient affected by hæmorrhage. Foot of bed raised. Pituitrin 1 c.cm. injected; ergot by mouth. Uterus displayed good tone. Four hours later uterus was discovered greatly enlarged with blood-clot (about 15 oz.).

In conclusion, it should be pointed out that the definite diagnosis may be complicated by a ruptured uterus or hæmorrhage into the pelvic cellular tissues, but the lines of diagnosis and treatment outlined should cover nearly all cases of post-partum hæmorrhage.

Clinical and Laboratory Notes.

A NOTE ON DRAINAGE OF A PELVIC ABSCESS PER RECTUM

AND THE INDICATIONS FOR THE SELECTION OF THIS ROUTE.

BY HAMILTON BAILEY, F.R.C.S. ENG.,
SURGEON, DUDLEY ROAD HOSPITAL, BIRMINGHAM; GILLSON SCHOLAR, SOCIETY OF APOTHECARIES.

MY enthusiasm for drainage per rectum, in selected cases of pelvic abscess, was aroused when I was attached to the clinic of Mr. James Sherren, who often used this method.

The pelvic abscess to which I refer is one which is seen in surgical, as opposed to gynæcological practice and usually, but not necessarily, arises as a complication of acute appendicitis. As is well known, pus can accumulate in the pelvis without serious constitutional disturbance; it is therefore not surprising that these abscesses may attain considerable proportions before being recognised. The most characteristic symptoms to which they give rise are diarrhœa and the passage of mucus. The latter is of cardinal diagnostic importance, and is not sufficiently emphasised in current teaching; it is no exaggeration to say that the passage of mucus occurring for the first time in a patient who has, or has recently had, an attack of acute appendicitis, is pathognomonic of pelvic abscess

Rectal examination reveals a bulging of the anterior rectal wall, which, when the abscess is "ripe," becomes softly cystic. It is inaccurate to say that it fluctuates, unless fluctuation can be elicited between it and the anterior abdominal wall. Fluctuation cannot be tested with one finger.

Left to nature, a proportion of these abscesses burst into the rectum, after which the patient nearly always rapidly recovers. Deliberate opening into the rectum may be contemplated when the swelling is quite soft. Evacuation of pus by this method was extensively used 20 or 30 years ago, but the practice has fallen into disfavour, and has now been almost entirely supplanted by suprapubic drainage. We have not far to seek for the reason of this change. It is easy enough to mistake a loop of obstructed intestine occupying the recto-vesical pouch for a collection of pus. Again, a collection of pus in the pelvis does not necessarily imply that there is a confined abscess in this situation. In other words, rectal drainage is a blind operation, and has justly earned a reputation of being dangerous. All blind operations eventually fall into disrepute, for they are sooner or later fraught with disaster. Blind rectal drainage should be reserved for those cases where the history, the free discharge of mucus, the softly cystic swelling, and complete absence of abdominal rigidity, make the diagnosis of a localised abscess pointing in the rectum absolutely undeniable. If there is the slightest doubt—and it is sometimes difficult, particularly in postoperative cases, to be quite certain—laparotomy should be performed; but, having opened the abdomen in the doubtful case, having ascertained that there is no obstruction present, having gently felt a mass occupying the true pelvis, and having seen that that mass is completely walled off from the general peritoneal cavity, I submit that to close the abdomen immediately and then to drain the abscess into the rectum is a practice which fulfils the highest object of surgery. To choose the alternative (suprapubic) route for evacuating the pus seems most undesirable, if not positively mischievous, for of necessity Nature's barriers must be broken down and the general peritoneal cavity exposed to the dangers of a spreading infection.

Technique.—The patient is placed in lithotomy position. A rectal speculum is introduced and the swelling of the anterior rectal wall is seen. Very characteristic is the passage of mucus down the speculum. The mucosa overlying the swelling may be nicked, but this is unnecessary. A long pair of blunt-ended sinus forceps are taken and plunged into the swelling; the blades having been opened, pus pours down the speculum. Keeping the forceps still in the abscess cavity the speculum is withdrawn as far as the handles of the forceps allow. The right forefinger is guided by the forceps into the abscess cavity, after which the forceps and speculum are completely removed. A drainage-tube is then insinuated along the forefinger into the abscess cavity. This drainage-tube is long enough to protrude out of the anus, and, when in position, is secured to the anal verge by a stitch. The patient is nursed in Fowler's position and the tube removed on the fourth day.

Preliminary laparotomy and inspection have robbed rectal drainage of its terrors.

A CASE OF
SUBCUTANEOUS FIBROID SYPHILOMA.

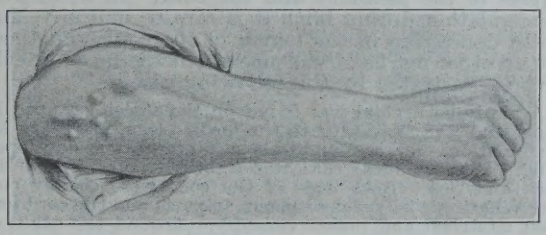
BY C. RICKWORD LANE, M.B., B.CH. OXF., D.P.H.,
PATHOLOGIST TO THE HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.

IT seems worth while to report the following case, attention having been called recently to the rarity of the condition by Dr. C. Worster-Drought.[1]

The patient was a chauffeur, aged 45, married. He had one living healthy child, one had died of "convulsions" in infancy, and his wife had no history of miscarriages. He had had no previous illnesses except venereal disease, stated to be gonorrhœa, when he was 20. His mother died of "heart trouble," and his father of cancer, both over 60.

About 20 years ago a lump appeared over the back of both olecranon processes at points where the arms rested on the well seat of the car he was then driving. They were small, single, and painless, and very gradually increased in size until 12 months ago, when the one on the right arm received a blow and a sore resulted. This kept breaking down, satellite nodules then appeared; at about the same time a second nodule appeared on the left arm, and a sore on the back of the right calf.

On the left arm there is a lump of cartilaginous consistency the size of a walnut over and partly attached to the posterior border of the ulna at its upper end. There is a smaller nodule distal to this. X rays show slight osteitis of the



Lesions on right arm.

posterior aspect of the shaft of the ulna. On the right arm there is a similar nodule, unattached to the bone, in a corresponding position, with several smaller nodules round it. X rays show no evidence of bony change in the ulna. Lastly, there is a thickened patch of skin measuring about 1¼ in. by ¾ in., brownish in colour, and not tender, on the back of the right calf. The pupils react normally, the knee-jerks are absent, and the blood Wassermann reaction is positive.

Histological Appearance of the Lesions.—The structure of all the lumps is similar, showing thick bands of almost hyaline fibrous tissue, between which is more richly cellular fibrous tissue infiltrated with small round cells, plasma cells, and in some places giant cells. The blood-vessels here show perivascular round-celled infiltration, and some of them endarteritis. No spirochætes were found in sections stained by Levaditi's silver method, and no tubercle bacilli were seen in a Ziehl-Neelsen preparation. The structure is that of a fibrosing gumma.

The points that seem worthy of special notice are the interesting exciting cause, the extreme chronicity of the lesions with the production of other similar nodules at a much later date, and the comparative freedom of other symptoms or signs except the absent knee-jerks over a prolonged period in a patient who only received antisyphilitic treatment probably with mercury for a short period after the acquisition of the disease.

I wish to express my thanks to Mr. W. H. Ogilvie, under whose care this patient was, for permission to publish details of his case, and also for the drawing here reproduced.

[1] THE LANCET, 1926, ii., 637.

A CASE OF
HOMICIDAL STRANGULATION OF A FŒTUS BY THE UMBILICAL CORD.

BY SYDNEY SMITH, M.D. EDIN., D.P.H.,
PRINCIPAL MEDICO-LEGAL EXPERT, EGYPTIAN GOVERNMENT SERVICE.

OCCASIONALLY a child is born with the umbilical cord tightly twisted round the neck, and if no assistance is at hand to remove the pressure death might quite conceivably result from strangulation. In such a case the lungs would not be inflated, but a certain amount of breathing might occur; the head may have been born with the cord loosely twisted round the neck and the child might breathe before the descent of the body tightened the cord. If it were not removed the body would present signs of live birth with the establishment of breathing and also signs of death from asphyxia.

Assuming this to be possible a person who wished to cause the death of a child might strangle it with the umbilical cord without incurring suspicion of homicide. It would be difficult, for, unless the placenta were born with the child the cord would have to be cut before it could be used as a ligature. This

would arouse suspicion, for if a child were strangled by the cord in the natural process of birth one would not expect the cord to be cut. Moreover, if the cord is tied round the neck tightly enough to cause strangulation it must be pulled and handled with some violence, which would cause considerable displacement of the Wharton's jelly. Finally, and this is most important, homicidal strangulation by the umbilical cord is never carried out calmly enough to prevent injuries to the tissues of the fœtal neck from the fingers of the assailant and the cord. In accidental strangulation during birth it is rare to find anything but a depression in the region of the cord, and there are no other marks of violence about the face or neck. This is illustrated by the following case :—

A newly-born child was found on the street wrapped in paper and was forwarded to the medico-legal mortuary for examination. It was found to be a full-term, well-developed child. The umbilical cord was tightly twisted round the neck and tied. Both ends of the cord were cleanly cut. The Wharton's jelly was displaced in parts and the cord had been stretched and pulled violently. Around the edges of the depression made by the cord there were numerous ecchymoses, and marks of finger-nails were observed on both sides of the neck and on the left side of the face. The ears, lips, and tips of the fingers were blue and the case presented the typical signs of asphyxia.

On dissection the lungs were found to fill the pleural cavities, were mottled red, and presented all the signs of lungs that had breathed. Fine froth was found in the trachea and bronchi. On placing the lungs in water they floated buoyantly, and after cutting into pieces and applying pressure every part still floated. Around the base of both lungs, on the anterior surface of the left lung, and on the surface of the heart there were numerous small hæmorrhages. The stomach and duodenum, removed separately, both floated. There was no food in the stomach and the rest of the viscera were healthy.

From the above examination it can be affirmed with certainty that the child was born at full term, that it breathed and lived in the legal sense of the term, and that it was killed shortly after birth by homicidal strangulation with the umbilical cord.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ORTHOPÆDICS.

THE first meeting of the session was held on Oct. 4th, when Mr. W. ROWLEY BRISTOW gave his presidential address on

ARTHRODESIS.

He said that among the changes in bone and joint surgery which had been evolved since 1912, both in this country and America, one of the most marked was the frequent resort to fusion of joint surfaces—i.e., arthrodesis. This must be regarded as destructive, seeing that the joint, as such, was destroyed, but as a rule it was preferable to the usual alternative—amputation—and the arthrodesis might cure the disease and abolish the symptoms.

Indications.—The indications for arthrodesis he conceived to be: (1) pain, (2) loss of function (with or without deformity). Both these often resulted from arthritis, including tuberculosis, concerning which latter there was marked difference of opinion, that he hoped would emerge in the discussion. Pain and loss of function might also ensue from trauma, and from paralysis the result of anterior poliomyelitis or of peripheral nerve injury. Treatment of paralytic scoliosis by spinal fusion was now on trial.

Contra-indications.—The contra-indication most often met with was fixation or loss of control of a neighbouring or corresponding joint, as in cases of fixed knee with a painful hip on the same side. Age he did not regard as so serious an argument against joint fusion as did many. It had been his practice, said the President, to treat all joint tubercle in children by conservative means, operating for it only in the adult. A study of end-results in series of cases so treated showed, however, forced an unfavourable view as to the efficacy of this treatment. Nevertheless, in his experience the result of the conservative treatment of Pott's disease was satisfactory, as was also that of such treatment of small joints. He contended that the ultimate results of conservatism in the case of tuberculosis of knee or hip were bad. In 50 cases of hip tubercle analysed by Mr. G. Perkins, the femoral head was diseased and altered in 41, resulting in fibrous ankylosis, with, later, adduction deformity. An important question was whether, when the head was affected, the hip should be arthrodesed, and if so, by what means? In the active stage of tubercle intra-articular arthrodesis did not produce bone fusion; but the methods of extra-articular arthrodesis, as advocated by Hibbs, of New York, and by the Boston school, gave this fusion, with stabilisation of the joint by means of a bridge of bone. The average stay in hospital of a patient with a tuberculous knee was very variable. Some children did better lying in bed wearing a Thomas knee-splint, others by having, after the acute stage was over, a weight-relieving caliper or patten-ended Thomas splint. Usually the commencement was in synovial disease. When the bone was affected in tuberculosis of the knee in children the President thought arthrodesis should be considered. His contention was that there was a type of joint which did not respond to conservative methods, and that each patient should be regarded as an isolated problem.

The President then proceeded to discuss the technique of the intra- and extra-articular methods of operating, remarking that extra-articular arthrodesis of the hip was a recent innovation, and that the procedure adopted by Hibbs was one which strongly appealed to him. Certainly occasions arose when it was necessary to fix the hip and stress was rightly laid on saving the periosteum. Where bone fusion had been done and patients so treated had subsequently died of intercurrent disease the specimens showed a firm arch posteriorly, and the fused joints between the articular processes. It was necessary, he said, to emphasise the use of arthrodesis in the treatment of painful joints following fractures or other trauma; it was the best for old mal-united ankle-joint fracture when arthritis was present. And not many subjects of fractured os calcis resumed full work. Wilson, of Boston, advocated immediate arthrodesis of the sub-astragaloid joint for fracture of the os calcis, as the patients were then able to return to their work in a reasonable time. Arthrodesis of the spine was practised in America for crush fractures of the vertebræ, while for low backache arthrodesis of the sacro-iliac joint was becoming popular.

The President had not found it necessary to fix either end of the clavicle for recurrent dislocation of the acromio-clavicular or the sterno-clavicular joints. In the case of the hip severe pain, with or without a crippling deformity, was what urged him to advise operation. When both hips, or a hip and a knee on the same side, were involved, arthrodesis of the hip was out of the question. Reconstruction of the hip, though still to be regarded as in the experimental stage, was well worthy of a trial. The operation was simple, and there was but little shock. The after-treatment consisted in moderate fixation for a month, after which the patient was allowed to get about. There should be frequent manipulation in the direction of extension and abduction. In conclusion he referred to the work of Dunn in this country in the treatment of paralytic deformities of the foot, his work having stood the test of time and resulted in a good functional foot. For many problems arthrodesis offered a successful solution, and especially was it valuable in relieving pain.

Discussion.

Mr. R. C. ELMSLIE said that 17 years ago he had collected a large number of cases of old excision of the knee for tubercle, done at various hospitals by

several surgeons as a short cut to a cure of the disease and to secure early ankylosis. The proportion in which there was bad deformity was very high. That deformity depended on two factors: interference with growth and bending of the bone at the point of fusion. He thought growth might be interfered with, not by disturbing the epiphyseal discs but by even going approximately close to them. If bony ankylosis was the best treatment for tubercle of bone, it should be done, but it should not be preached as the one method of treating tuberculous knees. In advocating fusion for tubercle there was the risk that it might be regarded as the routine operation, and that it might be done by men who were operators rather than surgeons.

Dr. W. T. GORDON PUGH said the great drawback in children's hospitals in the country was that children with tuberculous knees did not come at an early enough stage, but there had been a change for the better in this respect during the last two years. A result of this would be that arthrodesis would be necessary in a diminishing number of cases. He knew no more difficult disease to control than a tuberculosis of the knee which had passed beyond synovial involvement. In cases in which the great trochanter was much displaced upwards extra-articular arthrodesis would probably be necessary.

Mr. G. R. GIRDLESTONE expressed his agreement with the remarks of both the last speakers, and said it could not be too strongly insisted that there was no short cut of any kind to treatment of surgical tuberculosis. The disease was affecting the glands of the child as well as the joints, and he agreed that there was real danger in associating tuberculosis in a joint with operation on it for the cure of that disease. He agreed with Sir William Wheeler that spinal fixation was only part of the conservative treatment of spinal tuberculosis.

Mr. W. H. TRETHOWAN said that reconstructive operations were usually disappointing, and the final treatment seemed to be, mostly, some procedure to fix the joint. In very many cases a joint injured beyond the least trauma seemed to be ruined eventually, even though rest relieved pain for a time. He had not a good opinion of the operation of mushrooming—i.e., shaving off the whole of the head and leaving only the central portion of the neck. The small neck would not support the weight of the whole body. He did not agree with those who would refrain from setting up a high ideal of practice because some might do wrong operations.

Mr. NAUGHTON DUNN said that arthrodesis did not always relieve the pain of crushed fractures of the spinal column. Before operation was decided on in these cases it was well to fix the spine for a week or two; sometimes that relieved the pain, and rendered any operation unnecessary. Arthrodesis he had also found very valuable in cases of Charcot's disease of joints.

Mr. ALAN H. TODD expressed himself as favouring ankylosis of the spinous processes for aching backs and for crush fractures; in the Air Force, unfortunately, such accidents were not rare. He suggested that members of the Section as a whole should make more use of arthrodesis of the shoulder in cases of infantile paralysis. He had wondered what was the truth about the danger of activating, by operation, bygone tuberculosis, and referred to a case in which operation on a knee which had at one time been deformed by tuberculosis resulted in meningitis.

Mr. H. A. T. FAIRBANK agreed with Mr. Dunn about the results of arthrodesing Charcot joints; in selected cases he had found it very useful. He had attacked the acromio-clavicular joint by operation, and had had entirely satisfactory results. When tension made apposition difficult, he used wire or kangaroo tendon, and there was nothing to complain of.

The PRESIDENT, in his reply, said that in tuberculosis of joints he would operate only after prolonged rest and in carefully selected cases.

Reviews and Notices of Books.

MALARIA IN INDIA.

By Major-General Sir PATRICK HEHIR, K.C.I.E., C.B., C.M.G., M.D., I.M.S. (retd.). London: Humphrey Milford, Oxford University Press. 1927. Pp. 490. £2 2*s*.

SOME 17 years have elapsed since Sir Patrick Hehir brought out a modest work on the "Prophylaxis of Malaria" in India and out of it has been evolved the present compendious volume. There have been smaller treatises which have dealt with the many aspects of this great subject as it affects life in India, but the time is opportune for a comprehensive and authoritative work on the principal scourge on the empire, and Sir Patrick Hehir has been happy in his resolution to undertake it. We have here embodied the results of a life-work by one who has closely followed the subject from the very earliest glimmerings of truth to the fully expanded present knowledge of malariology.

The work is divided into three parts; the first concerns itself with the endemiology, epidemiology, and ætiology of malaria in India; the second with the clinical and pathological effects of the disease; while the third deals with the methods of prevention. There are also some 30 pages of appendices, for the most part statistical. In the opening chapters the overwhelming importance of malaria to the public health of India is indicated by the truly appalling statistics in relation to its ravages; the geographical distribution is illustrated by a coloured map specially prepared by Col. S. R. Christophers, and the meteorological conditions are also minutely considered. The consideration given to the anopheline mosquitoes in India, their nomenclature, habits, and characteristics is in proportion to their importance, and we have seen no other work in which this information is so minutely summarised. The malaria parasite and its life-history receive full consideration, as also do the clinical and pathological effects of the disease, and the vexed question of blackwater fever. Quinine, its preparation and chemistry, are subjects upon which it is particularly difficult to obtain information in books of tropical medicine, but here we are given a full description of its pharmacology in its bearing on the prophylaxis of malaria in so far as it concerns India. We may note that, in spite of the recent experimental evidence, the author still remains convinced of the value of quinine in prevention. The closing chapters appeal to the practical sanitarian, whom they will inform on anti-mosquito measures and the methods of drainage which must accompany them.

The volume is well illustrated by over a hundred text figures and 15 coloured plates reproduced from well-known works on malaria. Those calling for special mention are from Byam and Archibald's "Practice of Medicine in the Tropics," and the coloured figures of mosquitoes are particularly fine. The author is to be congratulated upon the fact that at the later end of an active career he has produced a volume which will rank amongst the classical works on malaria and which will be particularly useful to his many fellow medical officers in India.

RESEARCHES IN POLYNESIA AND MELANESIA.

By PATRICK A. BUXTON, M.R.C.S., D.T.M. & H., formerly Milner Research Fellow; Director, Department of Medical Entomology, London School of Hygiene and Tropical Medicine. Assisted by G. H. E. HOPKINS, M.A., F.E.S. Published by the London School of Hygiene and Tropical Medicine. 1927. Pp. 260. 10*s*. 6*d*.

Dr. Buxton has produced a noteworthy and readable account of his researches in Western Samoa, the Ellice and Tokelau Islands, and, finally, of his travels in the New Hebrides in the latter half of 1925. His work is in direct continuation of a number of expeditions to the Pacific Islands which have been undertaken by the London School of Tropical Medicine during the last 17 years. Leaving England in November, 1923,

Buxton and his party made their way through Panama, where they were given opportunity to study the public health arrangements of the Canal zone, to New Zealand. Travelling through Fiji they reached Apia in the middle of January, 1924. For the whole of 1924 and 1925 Dr. Buxton made Apia Hospital his base, and thence was able to make trips further afield. He gives a description of the geography and structure of the islands, and comments on the geology, flora and fauna. His notes on the climatology of Samoa include a mass of accumulated data of considerable value, such as solar radiation, rainfall, atmospheric humidity, wind, evaporation, and katathermometer readings. Dr. Buxton has, moreover, devised a new instrument—the radiation integrator in vacuo—which showed the monthly irradiation to be as high as 12 per cent. of the annual total in February, when the sun was vertical, and as low as 6 per cent. in June and July, when the sun was furthest from its zenith.

The third part of the volume deals with medical entomology—the natural and introduced species of the island insect fauna. We learn incidentally that the common flea was introduced to Rarotoga in 1820 by Goodenough, who discovered that island; "the placid natives of Aitutakai, observing that the little creatures were constantly restless and inquisitive, and even at times irritating, drew the reasonable inference that they were the souls of deceased white men." As to the mosquitoes, south and east of the New Hebrides, the genus anopheles is absent and no malaria occurs in the Loyalty Group, New Caledonia or any part of Polynesia. *Anopheles punctulatus* and malaria occur eastwards as far as 170° E., and southwards as far as 20° S. Outside this area, malaria is found nowhere except in Aneityum, which is only a fraction of a degree south of 20° S. The factors underlying this peculiar distribution have still to be ascertained. In the entomology of the New Hebrides the morphology and larval characteristics of *A. punctulatus* take a premier place. A large amount of work on the bionomics of the Culicidæ of Samoa has been done, especially on the irritating insect known as *Aëdes kochi*, and upon *Aëdes variegatus*, the chief vector of filariasis in Polynesia. Fine line drawings illustrate this portion of the report, and beautiful photographic plates of the breeding places of this insect are included. An account of intricate work directed towards evolving means for reducing the prevalence of this mosquito occupies over 100 pages of the report. Dr. Buxton's efforts have greatly extended our knowledge of this particular mosquito. We look forward to the appearance of future volumes which will contain the results of his pathological observations.

Evolution of Preventive Medicine.

By Sir A. Newsholme, M.D. London: Baillière, Tindall and Cox. 1927. Pp. 226. 11*s.* 6*d.*

In this interesting book the civil servant's urge to present exact facts is tempered by the scholar's delight in his subject, as when the author tells the history of plague with regard to a dawning appreciation of infection. We learn how in time of food scarcity, in 664, God was solicited in prayer to remove by some species of pestilence the burdensome multitudes of the inferior people, and of how the pestilence came, but fell alike upon the authors of the petition and the lower orders.

The evolution of preventive medicine is here traced from belief in supernatural causation of disease to knowledge based on ascertained facts. Error and truth, we are shown, often struggled together, the weight of accepted authority usually tipping the beam. But little over a century ago progress had hardly emerged from the twilight of futile libations, amulets, charms, and witchcraft. Differentiation of the infective fevers had hardly commenced and all were vaguely, but not unwisely, ascribed to filth. Cleanliness of person, of food-supply, and of home, banished the louse, excremental contamination, and the flea, and with them typhus, typhoid, and plague; even though early sanitarians wrought better than they knew. We are well reminded of the debt we owe to Harvey, Sydenham, and Jenner, and to men like John Snow and William Budd, to Chadwick and Southwood Smith, to Farr and Simon; each in his day fought and won an uphill fight for dawning knowledge against apathetic prejudice, and we who therefore live in a sanitary age find it hard to appreciate how life was lived when ordure was flung into the reeking streets, when no water in a town was safe to drink, when only 250 out every 1000 children born attained the age of 5 years. The author shows good reason why he is no mere *laudator temporis acti*. It is good for us to accompany him when he tells what we owe to Wendell Holmes and Semmelweiss, to Pasteur and Koch, to Takaki and Manson, and to bow our heads in thanks that these and others tilled the land where we reap the harvest of health. A second volume is promised dealing with more recent advances.

The Harvey Lectures, 1925–26.

The Harvey Society of New York. London: Baillière, Tindall and Cox. 1927. Pp. 229. 18*s.*

The Harvey Society of New York, which exists to promote lectures by eminent laboratory workers on the scientific branches of medicine, publishes every year a collection of the most valuable of the papers read before it, and most of the greatest names in research are to be found in its list of honorary members. The latest of these volumes illustrates the scope of its activities. The first paper, by Dr. F. R. Nager, of Zurich, surveys the recent progress of experimental otology, a branch of study which has been handicapped by the difficulty of obtaining reliable histological material. Dr. John Northrop, of the Rockefeller Institute, contributes a treatise on the dynamic chemistry of pepsin and trypsin digestion, and Dr. Warren Lewis, of the Carnegie Institution of Washington, an account of the metamorphosis of mononuclear cells into macrophages, giant cells, and epithelioid cells. The chemistry and physiology of the parathyroid glands are dealt with fully by Dr. J. B. Collip, of Alberta University, whose experiments have demonstrated the part played by these glands in phosphorus as well as in calcium metabolism. "Empiricism and Rationalism," by Dr. E. B. Wilson, professor of vital statistics at Harvard, describes the working of both these methods of ascertaining truth, and their significance to the statistician; his paper reminds the reader that columns of figures which appear so solid to the grasp are liable to disappear like mist under intensive criticism, and that the accurate summing-up of results or observations is a most complex task. The practical importance of statistical science as applied to medicine is well shown in the lecture, by Dr. Knud Faber, of Copenhagen University, on the progress of medical therapy. Statistics alone made possible the work of Pierre Louis in creating out of chaos many of the disease-entities which a century of medical practice have confirmed, and in establishing the probabilities of their cure by given processes. Dr. Faber points out that the statistician alone can give the research worker a gleam of hope that his results may be of real general value. The great advances of substitution therapy, serum therapy, and chemotherapy were made possible only after a definite disease had been discovered and experimentally reproduced, and after the observations of experiment or empiricism had been illuminated by numerical statistics. The seventh lecture is a contribution by Dr. B. Brouwer, of Amsterdam, to the comparative anatomy of the nervous system, in which he discusses the functions of the vital and non-autonomic sensory systems at various stages in evolution.

A society which can obtain contributions as important and diverse as these has an obvious value to medical science. Not only laboratory workers but all who are interested in the vast and patient work on which their everyday practice is founded will find in these lectures inspiration and encouragement.

LECTURES ON INTERNAL MEDICINE.

By KNUD FABER, M.D., Professor of Internal Medicine, University of Copenhagen. New York: Paul B. Hoeber. 1927. Pp. 147. $3.00.

IN reprinting the four lectures he gave in the United States last year Prof. Knud Faber has provided an exciting volume for physicians, house physicians, and all serious students of medicine. Is achylia gastrica the expression of an underlying gastritis? Is the anæmia of Addison merely one variety of a group of severe anæmias, all of which are of intestinal origin? Is there a form of alimentary glycosuria which is not diabetic, although accompanied by hyperglycæmia? In each of the three lectures which form the first three chapters Prof. Faber answers "yes" to all of these questions, and the instructed reader, realising the importance of these problems, will delight in the author's masterly defence of his thesis. The laboratory worker will also find food for reflection in the book. For each of these lectures raises points of doubt stimulating to the pathologist. To what extent may the cases of achylia here enumerated be accepted as absolute? Is the risk of post-mortem change definitely excluded in the microscopic specimens from which the evidence of gastritis was chiefly derived? Is it true that there is no absolute method of diagnosing pernicious anæmia from the blood-picture? And are the micro-methods of blood-sugar estimation as accurate as is here assumed? All these questions spring to the mind, and it is in the doubts which it arouses, as much as in the clearness of its exposition, that the book is a stimulating and delightful one.

LABYRINTHINE VERTIGO.

Les Vertiges Labyrinthiques. Par ANDRÉ MOULONGUET, Oto-rhino-laryngologiste des Hôpitaux de Paris. Paris: Masson et Cie. 1927. Pp. 165. Fr.18.

THE examination of the function of the vestibule and semicircular canals is highly intricate. Moreover, the development of experiments designed to elucidate their action, together with the clinical methods which depend on them, is so recent, that it is extremely difficult for the learner to obtain a good grasp of the subject. In this little monograph a very successful attempt is made to present the matter in a clear light. After a short chapter on anatomy, the physiology of the semicircular canals and of the otolith apparatus is described. There follows a practical section on examination of the patient, and a useful chapter on the differential diagnosis of labyrinthine from other forms of vertigo; and, finally, a helpful summary of the various aural lesions in which vertigo occurs. This is a thoroughly practical little book, which well repays study.

APPLIED PHYSIOLOGY.

By SAMSON WRIGHT, M.D., M.R.C.P. Humphrey Milford, Oxford University Press. Pp. 418. 15*s*.

Dr. Wright has given in this volume an account of those functions of the human body which are most commonly deranged by disease, and of the alterations that disease effect. Wherever possible the function, normal or abnormal, of any particular organ is illustrated by reference to the corresponding normal and pathological states in man.

Emphasis is laid in the preface on the importance of bringing the student of physiology early into touch with the signs exhibited by patients suffering from those derangements of function of which human physiology gives a ready interpretation. But while the reactions of man to changes in his environment are well shown, the comparative and physico-chemical branches of physiology are not neglected, and it is made clear to what extent the analysis and interpretation of some human pathological states is facilitated by their study, for example, in the conception of conduction with decrement in the various forms of peripheral neuritis. It seems questionable if any useful purpose is served by introducing into a work of this scope information dealing with problems so involved as that of the sympathetic innervation of voluntary muscle, and with results still lacking confirmation, such as those of Voronoff's grafting experiments in man.

We note misprints on page 211, where $\frac{100}{3\cdot5}$ should be $\frac{100}{15}$, and on page 304, where "impurities" should presumably read "impulses."

A large amount of valuable information, including the most recent additions to knowledge, is here condensed into a comparatively small space, and still the book remains readable. It should prove most useful to those reading for their primary F.R.C.S., final M.B., or for the M.R.C.P. Many figures are included, and references to important papers from which information has been drawn are appended to each section.

RADIOLOGY IN MEDIASTINAL AFFECTIONS.

Essai sur une Nouvelle Radiologie Vasculaire. By MANOEL DE ABREN. Paris: Masson et Cie. Pp. 214. Fr.38.

RADIOLOGY plays an important part in the diagnosis and treatment of mediastinal affections, and reveals more than does clinical examination. In recent years much work has been done on the radiological examination of the mediastinum, especially by the French school, and elaborate methods of measurements of the heart and great vessels have been evolved. Dr. de Abren deals chiefly with some modifications of these methods, and more particularly with the measurements of the aorta in health and disease. The author explains his technique and theories clearly, and the work is profusely illustrated with photographs, diagrams, and radiographs.

RENAL DISEASE.

Modern Methods in the Diagnosis and Treatment of Renal Disease. Third edition, enlarged and revised. By HUGH MACLEAN, M.D., D.Sc., F.R.C.P., Professor of Medicine, University of London. London: Constable and Co., Ltd. 1927. Pp. 135. 12*s*.

THE publication of a third edition of this monograph is an indication that the value of functional renal tests in the diagnosis and treatment of renal disease is becoming widely recognised. The tests described in previous editions have not been altered or added to. Prolonged use has proved their reliability and, properly used in conjunction with clinical examination, they are convenient and informative.

The chapter on treatment is the only part of the book that has been rewritten. In this section the discussion on diet is especially valuable. The author points out that there is no evidence that a moderate protein intake is a cause of nephritis or arteriosclerosis, and that the tendency to give a very low protein diet is in many cases wrong, because its debilitating effect may be worse than the disease itself. Even if there is considerable albuminuria it is a mistake to limit excessively the intake of protein for long periods, and when renal tests indicate a marked improvement of function in spite of the albuminuria, exceedingly good results may be obtained by giving a comparatively large amount of protein. It is, however, important to give fruit and vegetables with protein as early as the disease allows. The diet sheets for use in acute nephritis should prove very useful. The indications for and value of a salt-free diet and high-protein diet are also clearly discussed, and the chapter puts the treatment of renal disease on as firm a foundation as present knowledge permits.

This monograph gives the clinician a clear idea of the practical value of functional renal tests, and shows when and how they may be used to gain further knowledge when clinical observation has reached its limit.

ABNORMAL PSYCHOLOGY.

Readings in Abnormal Psychology and Mental Hygiene. Edited by W. S. TAYLOR, Professor of Psychology in Smith College. London: D. Appleton and Company. 1927. Pp. 789. 16*s*.

THIS is a psychological anthology of great merit. It is planned for students of general psychology, sociology, and education rather than for those who are intent upon a deep research into the subject of psychological medicine, but even the advanced psychiatrist will find it of value for its enormous bibliographical range. It deals shortly with crude mental disease and with academic psychology, and is chiefly devoted to a survey of those functional disorders of the mind which cause so much and such intense misery without incapacitating their victims from living in society. Every facet of these ills is treated very fully. The method has been to select for each section the extract from modern psychological literature in which the editor judges that the matter has been treated most clearly and usefully for the student. The choice has been made from a very long list of authors, which includes some of the first writers on this subject in the world. Janet, Rivers, James, Jung, and Morton Prince are liberally drawn upon. Moreover, instructors using the collection as a class text-book will be enabled to develop further what topics they wish by using the reference-lists which end each chapter. The result is a very fair survey of modern thought in the realm of functional abnormalities.

New Inventions.

A SIMPLE LIGATURE APPLICATOR FOR TONSILLAR AND OTHER DEEPLY-SEATED VESSELS.

THE apparatus consists essentially of a glass or metal tube of about four inches in length and a metal carrier, somewhat longer, with a notch at one end. The ligature, preferably of catgut, is doubled and pushed through the tube by means of this carrier (Fig. 1). The projecting loop of the ligature is then

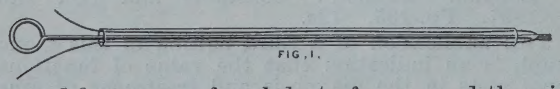

FIG. 1.

secured by means of a pledget of gauze and the wire guide removed. One loose end of the ligature is then marked by means of ink or a knot in order to distinguish it. A half knot is then made in the other loose end and the marked one pushed through it. The half knot is then tightened (Fig. 2). We thus

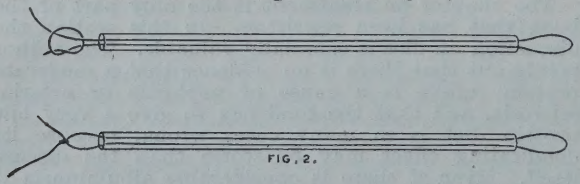

FIG. 2.

have a sliding loop round the marked end. The loop (which may be considerably larger than is shown in the illustration) is passed over the forceps with which the bleeding vessel has been clipped and pushed down by means of the tube till it encircles the vessel. If the marked external end is then pulled, the loop on it will pass down the tube and grip the vessel (Fig. 3 (2)).

As it will be found that the non-marked end should be about twice the length of the other, the "doubling" may be made at the junction of the first and middle thirds. The drawing down and tightening of the knot may seem to occasion an undesirable amount of friction on the vessel; it can therefore be closed up on the forceps until only a small loop is left to be slipped on to the said vessel (Fig. 3 (1)).

After numerous trials on a piece of gauze I tested it on the living subject, using catgut for the ligature of a vessel during a tonsillectomy. The ligature was effected without difficulty, and when I saw the patient four days later it held firmly even when I tried to pull it away with some force. This experience has now been frequently repeated. When a glass tube

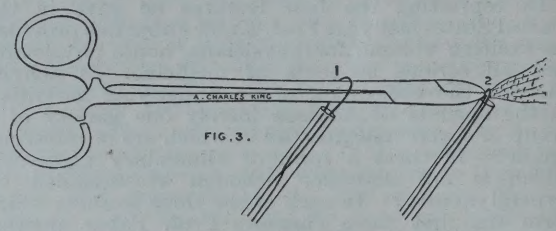

FIG. 3.

is used we have the satisfaction of seeing the knot passing down it as well as judging by sense of touch.

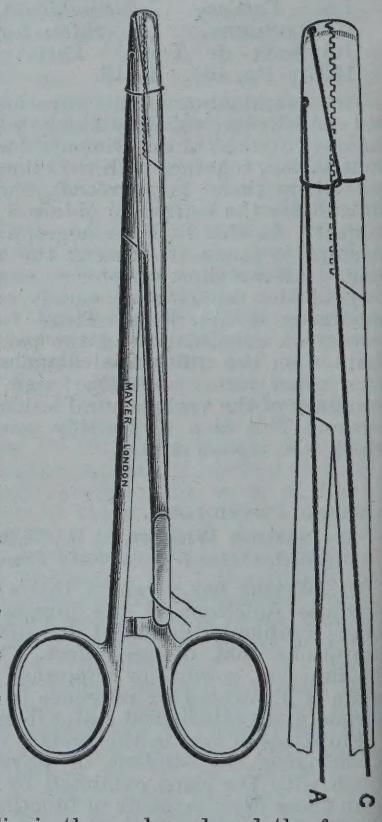
The slip-loop was first brought to my notice by C. G. Coakley, of New York, but the tube is my own idea, and, so far as I can see, is likely to facilitate the ligation of vessels in other regions as well as the throat, such as the upper part of the wound cavity in the dissection of malignant or tuberculous glands in the neck, and possibly also in operations in the thorax and abdomen.

The carrier and tube were made for me by Mr. Charles King, of Devonshire-street, London, W. 1.

JAMES DUNDAS-GRANT, K.B.E., M.D. Edin., F.R.C.S. Eng.

PRESSURE FORCEPS.

THE pressure forceps illustrated below, though designed for use especially in tonsillectomy, will be found useful wherever access to a bleeding-point is limited. The forceps consist of an ordinary straight pair, provided with a small, smooth hole in one beak as shown. The ligature is threaded through this hole and the free ends retained in the clip provided. Having secured the bleeding point, one end of the ligature (C) is withdrawn from the clip and passed around the shank of the forceps to include the other strand (A) of the ligature, making a half-hitch. By pulling on the strand retained in the clip (i.e., A), the knot (B) is drawn down to, and over the point of the forceps to encircle the tissue, forming, as it does so, a complete half-knot. The strand of the ligature retained in the clip is then released and the forceps withdrawn altogether, or, if necessary, only partly when they may be used as a guide to a second knot.



I am indebted to Messrs. Mayer and Phelps, of New Cavendish-street, W., who have made them for me.

NORMAN M. EADIE,
House Surgeon, Golden-square Throat, Nose, and Ear Hospital.

THE LANCET.

LONDON: SATURDAY, OCTOBER 8, 1927.

THE UNIVERSITY OF LONDON.

SOME three months ago it was announced that the purchase of the Bloomsbury site by the University of London from the Duke of BEDFORD had been completed, £400,000 having been received from the Rockefeller Foundation, whose splendid services to metropolitan education will never be forgotten, and £125,000 from a special Government grant. The University thus enters upon a stage of development where not only will it be able to discharge its great work better, but where it can realise in a fuller manner the extensive promise of that work as implied by its title. The recent articles in our columns written by Mr. PERCY WALLACE, who was Secretary to the Senate from 1901 until 1923, supply a succinct story of the University. They explain the constitution and the machinery of working, and show how great a claim upon the sympathies, not only of the metropolis but of the Empire, the progress of the University should possess. This progress is necessarily regarded with particular attention by medical men, for the faculty of medicine is, within the elaborate construction of the whole, one of the most elaborate divisions, and no stress need be laid upon the high position which the medical degrees of the University take, and have always taken. At the same time the medical curriculum has been responsible for many vexatious dissensions in the history of the University, owing to the fact that medical education cannot be conducted without the intermediary of special schools and training which were not contemplated in the original ideals of the University. The existing constitution of the University is complicated, but it has been designed, with a reiterated amount of expert advice, to meet conditions of great difficulty, and now seems to be meeting them fairly.

What is being accomplished will be better understood if some of these difficulties are appreciated, as they are set out in Mr. WALLACE'S lucid statements. The University was founded originally as an examining body of an Imperial character, and its great default in respect of teaching in the metropolis began to make itself acutely felt some 45 years ago. The teachers of medicine of the metropolitan schools were in the forefront of the agitation for reform which then arose, because of the difficult position in which the London medical student was placed in respect of obtaining medical graduation. It is true that examiners appointed by the University were ready to pass for graduation such London students as satisfied their tests, but the University was in no general relation with the teaching of the students or with the organisation of the London schools at which the training was given. In 1885 the Royal College of Physicians of London and the Royal College of Surgeons of England approached the University with a suggestion for the recognition of their diplomates for a London degree. Nothing came of this, nor of a scheme by which the Colleges themselves should found a one faculty university, nor of one under which University College, London, and King's College, London, should form the nucleus of a new university, nor of a design for a new university to be established for London students, leaving the old university to discharge its Imperial functions. All these propositions were so open to criticism that their failure cannot be wondered at, despite the ingenuity and industry with which they were put forward; but at least they served a common purpose in showing how fundamental and widespread was the dissatisfaction with the teaching provisions of the University as it existed. In 1892 a Royal Commission on the subject was appointed—the second with a similar reference—and this body reported two years later, when its recommendations, which form the basis of the present organisation of the university, confirmed the substantial grounds of claims for reform. Under this report the University was divided into internal or collegiate students and external or non-collegiate students, and a set of statutes and regulations of great scope and particularity emerged from the Statutory Commission set up after the issue of the report. It is at this point that Mr. WALLACE has taken up the long tale in our pages, and has succeeded in explaining to the London student the present working of his own University, seen from the teaching aspect.

It can be understood that the promulgation of the statutes and regulations produced vast relief among all those who had rejected the various schemes of reconstitution, but no doubt the relief has been succeeded by some bewilderment owing to the complicated nature of the new procedures. Many earnest students of education have failed at first to recognise either the pattern or the objects in view, and the probability of confusion will be fully appreciated by those who read Mr. WALLACE'S description of the present University and of the machinery for its conduct; the embarrassments of the faculty of medicine will be understood as arising from the peculiar situation of medical students, who are alike "external" and "internal," the former because their provenance is world-wide, and the latter because their places of education as well as their examinational courses are subject to control outside the University's authority. It is not possible to admit medical students to graduation whatever the methods in which they may have prepared for their tests: medical registration is necessary for the legal practice of medicine, and is only granted as a result of standard examinations following upon a curriculum supervised by the General Medical Council. From this has sprung prolonged controversy. During the sad period of agitation to which we have referred, and of which a full history will be found in the pages of THE LANCET,[1] this is the fact which created obstacles that at one time seemed insuperable, if justice was to be done. A way out appears to have been found for a balancing of all claims while bringing the University of London into close relation with the teaching of medicine at the medical schools of the metropolis, and this without infringing upon the rights of those students which the University had in prime consideration at its origin. With the fundamental question of a central home settled, and with the wheels of activity revolving harmoniously, the outlook is good.

ERYTHEMA NODOSUM.

THE curious little outbreak of erythema nodosum, described by Dr. MAURICE MITMAN on page 751 of our present issue, recalls the work of ALFRED AUSTIN LENDON, of Adelaide, who in 1905, and again in 1925, adduced good grounds for renaming the condition "nodal fever." In a monograph published in London in 1905 he asserted that erythema nodosum is merely

[1] See, for a summary, THE LANCET, Sept. 3rd, 1898, p. 591 et seq.

the rash of nodal fever. To this disease he attributed a seasonal incidence in the spring, a highly inconsistent sex-incidence with a female preponderance, and an age-incidence well in keeping with other zymotic diseases. As a result of long personal observation of 62 cases in general practice he described the incubation period as about 14 days; the infectivity as mild; the prodromata as severe and precise, with invariable conjunctivitis, arthritic pain, and faucitis, and malaise approaching the early state of typhoid fever; the clinical course as resembling scarlet fever; a great liability to relapses; an anæmic and debilitated state in a long convalescence; and finally the rarity of second attacks. These views have never been generally accepted, and it is difficult to account for every case of erythema nodosum so neatly.

In reviewing the whole literature recently G. F. WALKER[1] has reclaimed LENDON'S work but has pointed out that the priority for the conception of nodal fever belongs to HARRISON, of London, who addressed the Dermatological Society in 1900 to the effect that erythema nodosum, and several other diseases such as herpes, are capable of sharper definition into acute febrile infectious maladies. WALKER has drawn attention to the persistence with which records appear of erythema nodosum attacking two, three, or four persons in the same environment, and also to two little epidemics, accounts of which have already been published. But his paper is also concerned, on the one hand with the final relegation out of clinical medicine of the supposed association between erythema nodosum and rheumatic fever, and on the other hand with the undoubted association between certain types of erythema nodosum and tuberculosis. The traditional association between erythema nodosum and rheumatic fever dates back to the writings of STEPHEN MACKENZIE in 1886. This association was not then shown according to modern standards, but though MACKENZIE'S original article does not contain one scrap of evidence whereby erythema nodosum can be placed in the rheumatic series as we understand the term to-day, yet his obsolete and fallacious conclusions have been solemnly accepted for half a century. Clinical evidence of the association is singularly lacking.

The story is very different when we examine the allegations of its association with tuberculosis; not without good reason did it receive the adjective "ominous." According to numerous records in European and American literature erythema nodosum enjoys a position of certainty as a herald of tuberculosis, and there are hundreds of cases on record in which it has been followed, sometimes rapidly, by pleurisy, phthisis, or the lesions of surgical tuberculosis. Two recently recorded fatal cases of erythema nodosum were found at autopsy to be cases of miliary tuberculosis, and tubercle bacilli and a tuberculous architecture have sometimes been found in the nodes. Bazin's disease, or erythema induratum, which is acknowledged to be tuberculous, usually starts as an indolent relapsing erythema nodosum. Among the more weighty recent communications on the association is the paper by R. MASSINI, of Basle, which was recently noted in these columns.[2] A complete survey of the incidence of erythema nodosum in tuberculous patients, and an examination of the strange selective nature of the disease, together with a solution of the problem of the odd sex and seasonal incidence even in frankly tuberculous cases, and an authoritative announcement of the real prognostic significance would be of considerable value. Sometimes urticaria has qualities which make it resemble erythema nodosum and the same may be said of erythema multiforme. Gummatous lesions and excretion rashes have likewise been confused and it is probable that a big node in erythema nodosum is occasionally incised because of its resemblance to cellulitis. Erythema nodosum is a manifestation rather than a sharp clinical entity, and should no longer be entangled with the ætiology and prognosis of the rheumatic series. Its occurrence should stimulate a search for a tuberculous lesion, whilst authentic evidence of the infectivity of the disease and examples of its exanthematous nature are always worth recording.

THE ROYAL ARMY MEDICAL CORPS.

IN the Students' Number of THE LANCET we stated a few weeks ago that the publication of the Royal Warrant of 1926 had removed many of the grievances of the officers of the Royal Army Medical Corps—grievances which had been pointed out frankly in our columns on many occasions. And we went on to recommend the Service as a career to young medical men. So that it has been a matter of regret to see the Service in certain places singled out for adverse criticism. Confidence has only recently been restored, and we think that those who are depreciating the opportunities of the young doctor who joins the Corps to-day have remained in considerable ignorance of what those opportunities now are, and any effect such words may have will be to retard an onward movement that is already taking place. It may be fairly expected that the Deans of the medical schools which are now opening for the October session will put the matter in the right light before their students. Young qualified men are showing a comprehension of the situation, for the competitive examinations for regular commissions, which had been in abeyance for some time, are now to be reinstated. The gist of the regulations for admission to the Service will be found in the Students' Number and in the "Conduct of Practice," while they can be obtained in full from the War Office; our advice to those who feel, after the study of the information, that a career in the Army would be an acceptable one, is that they should not delay to act. The rates of pay and allowances are good, the opportunities of post-graduate study are generous, and the work is varied and interesting; a quick decision to compete for a commission will have its reward in the acceleration of promotion.

Here are some points for the man to think of who is debating the matter in his mind. The improvements in the Service which have been made during the past 12 months in pay and general conditions of service are substantial, and the prospect of rapid promotion accompanies these changes. The pay and allowances of an unmarried Lieutenant now amount to approximately £511 a year, while a Captain, if unmarried, gets at present rates £617, and if married £709. The figures may not tempt those who think only in terms of the positions achieved by the most pecuniarily successful of the profession; but they will not be considered inadequate by those who feel that they are entering the Service from a deliberately exercised choice of the career with its many-sided openings. The rates of pay increase with promotion in rank and years of service till they reach the maximum of over £2000 a year, and in addition each year of service carries its element of gratuity or pension. The pace of promotion must be variable, but an officer is eligible

for promotion to the rank of Captain on the completion of three and a half years' commissioned service, and to the rank of Major on the completion of 12 years' commissioned service, provided that in each case he has passed the necessary examination and is recommended for such promotion. The recognition of merit as a factor for progress in the Service runs, it will be seen, throughout, for promotion to the higher ranks is by selection. The occurrence of vacancies must dictate the rate of promotion; but during the past year, we learn, 23 Majors were promoted to the rank of Lieutenant-Colonel.

One feature of the present conditions of service should be specially attractive to newly qualified practitioners. Those who take up a hospital appointment can, under certain conditions, get ante-dates to their commissions. In this way the time spent in acquiring the experience which comes from holding a hospital appointment will count as time in the Army. Hence the value of joining the Corps soon after qualification, so as to be quickly ripe for promotion, has no longer to be set against the value to a young doctor of holding house appointments; instead of these appointments being an indirect deterrent to advance by postponing entry to the Service, they have become a definite asset, while the ante-dating of the commission secures the young man from loss of seniority. The advantages of joining the Corps while it is short of junior officers are obvious, for it would seem that those who obtain commissions in it now cannot fail to find themselves in really responsible places while still in early middle life. And if they are minded to retire after seven years with the Corps, and while still at an age when many practitioners are just beginning to reap the fruit of their training, they will have earned a gratuity of £1000 to assist in their establishment of a civil practice.

A LEADER IN PHYSIOLOGY.

THOUGH currents of action in the heart were demonstrated as long ago as 1856, their systematic investigation did not come into the field of practical medicine until 1903 when the string galvanometer was first used to record them. This advance was due to Prof. WILLEM EINTHOVEN, whose death occurred at Amsterdam on Sept. 29th, and it was only one of many services rendered to science by this distinguished physiologist and physicist. Born at Samarang, in Java, in 1860, he was appointed professor of physiology at Leiden at the early age of 25, and spent the remainder of his life in this old and quiet city. Profound learning and elaborate research in time gained him world-wide recognition in various branches of physics, but his fame will chiefly rest on the cardiological work to which his later years were mostly devoted. The electrocardiograph as it is used to-day is of his devising, and the notation of its tracings—the well-known "P.Q.R."—is that which he suggested. The clinical application of his methods, notably by Sir THOMAS LEWIS in this country, has enormously enlarged our knowledge of the heart in health and disease, and EINTHOVEN well deserved the Nobel Prize for physiology and medicine bestowed on him for 1924. In the same year he was made an honorary member of the Physiological Society, and the respect in which he was held by English physiologists became personal as well as academic when he acted as their host on the Society's visit to Leiden. The latest of his English honours was foreign membership of the Royal Society, to which he was elected in 1926.

Annotations.

"Ne quid nimis."

THE NEW LIFE-TABLES.

IN this issue and the last we have summarised the contents of a volume containing the new national life-tables and the Government actuary's report thereon. This report is of particular value because Sir Alfred Watson's knowledge of and interest in the subject matter of his analysis are such that he has completely avoided any temptation to dwell mainly upon those technical aspects of construction and graduation which, interesting and important to professional statisticians and actuaries, are almost unintelligible to the average reader. Indeed, he has not disdained to point out that the real value of life-table constants which enjoy great popular prestige, such as the expectation of life, is restricted and that there are cases where to present the facts of mortality in life-table form at all has little to recommend it.

In general, the results of this analysis of *post bellum* mortality are gratifying. At most ages, especially in childhood and early youth, the people of England die at much lower rates than before the war. It may be that the stagnation—amounting to a slight backward movement in the data for women—between the ages of 20 and 30 is a war effect; in any case it is not very serious. After four years of desolating war and a great pestilence, in an epoch of industrial crisis and general disillusionment, judged by the test of mortality, we stand better than at the end of an epoch of peace and prosperity. It may be that there is some illusion in this. Few men in middle life or beyond it can altogether escape the feeling that life as lived now in England has a touch of unreality. It seems hard to reconcile it with the economic facts. How can it be that the citizens of a country supporting a fantastic burden of taxation, with a million workers idle and restricted markets, still on the average maintain life at a higher standard of comfort and even of luxury than a generation ago? Are we living in the shadow of some great disaster? The medical analogy to this economic impression would be a doubt whether morbidity, not yet reflected by mortality, is so favourable. Since morbidity cannot be measured with the unambiguous precision that attaches to mortality, the point must remain speculative. But, without passing beyond the circle of ascertained experience of mortality, there are some features brought out by Sir Alfred Watson which are not agreeable. Of these undoubtedly the most impressive are the regional differences. The comparison of the county boroughs of Northumberland and Durham with all England and with the rural districts of the eastern counties is an example. For every 100 of the males who reach 60 by the Northumberland and Durham experience, 141·8 attain that age in the eastern counties. Nor is this wholly due to the unfavourable conditions of life in infancy in the northern towns, for it appears that for every 100 males aged 20 who reach 60 in Northumberland and Durham, 125·5 will do so in the eastern counties. This is not wholly an occupational difference, since the figures for women also offer a contrast; using the last test—viz., the proportion of survivors from 20 to 60—the county boroughs of the north show 100 survivors compared with 115 in the rural districts of the eastern counties. We may pass over this with the remark:

> O fortunatos nimium, sua si bona nôrint,
> Agricolas . . . .

but it is hard to believe that in this small country there ought to be so vast a disparity. Favourable as is our mortality experience on the whole, such contrasts as these—which, by restricting the areas, might be made still more striking—show that there is still much to be done before the worst districts or occupations are raised to the level of the best.

SEX AND INTERNAL SECRETIONS.

THERE are good reasons for believing that the primary sex of an individual is determined by the constitution of the chromosomes of the egg and spermatozoon from whose conjunction it originates. Cytologically the whole of a woman is female and the whole of a man is male. In some invertebrates it seems that sex is finally and irretrievably fixed in this way. But higher animals have evolved a mechanism which is at once more complicated and more labile. If a mammal develops normally, the nature of the chromosomes determines the growth of the appropriate sex gland, ovary or testis as the case may be, and it is the internal secretions of these glands which determine those bodily and mental qualities which for practical purposes decide to which sex anybody belongs. Removal of the sex glands neutralises the individual; eunuchs are not feminine but infantile, ovariotomy leads to loss of sex, not to maleness. We have thus a primary chromosomal sex (male or female) and a secondary gonadic sex (masculine or feminine), and experimental surgery has shown that higher animals have so far escaped from the influence of their sex chromosomes that the primary and secondary sexes of the same individual do not necessarily correspond. For it is possible to masculinise a female by substituting testicle for ovary and to feminise a castrated male by implantation of ovarian tissue. The predominance of the sex gland is thus clear. But it is not final, and it may be influenced and indeed overridden by other circumstances, and particularly by the products of other ductless glands. Experimentally there is a variety of evidence. Prof. F. A. E. Crew, for example, has shown that feeding young cockerels with thyroid leads to feminine feathering while thyroidectomy causes the feathers of female chicks to tend towards the masculine type. But the most striking instance of such an influence is afforded by human pathology in the tumours of the suprarenal cortex which are associated with sex changes. The few examples which have been found in males have occurred in children who have shown a general excess in growth and strength ("infant Hercules") and an extravagant precocity of external sexual development. Much more frequently these tumours have occurred in adult females in whom they lead to physical and psychical masculinisation. The realisation of the association, which we owe largely to Prof. E. E. Glynn, of Liverpool, has resulted in its recognition during life and in several instances to the happy removal of the tumour and a consequent restoration of femininity. The effects of operation appear to have made it quite certain that the tumours cause the masculinisation. They were described very clearly by Dr. Gordon Holmes and Mr. Percy Sargent in 1925 in a young woman of ample sexuality, and are brought out quite plainly in the case described by Dr. C. G. Murray and Mr. Graham Simpson in our present issue. In the other case, described by Mr. C. M. Kennedy and Dr. W. A. Lister, the patient unfortunately died before the results of operation could become manifest.

The explanation of this extraordinary phenomenon is very difficult. The tumours vary somewhat in detail; some are definitely malignant, some practically benign; some of slow, others of rapid growth. Histologically there is a general resemblance which in quite a number amounts almost to identity. There is little doubt that they all arise from the cortex of the suprarenal, and it is natural to suppose that they exert their influence by producing either an excess of the normal internal secretion of that organ or a secretion of abnormal kind. If the first alternative is correct, it ought to be possible to reproduce the condition experimentally, though we believe that the attempts to do this which have been made have so far failed. The second alternative recalls Prof. Glynn's remark that embryologically the suprarenal cortex is derived from the same source as the ovary and testis; it is possible that we have here a functional "reversion to embryonic type" familiar to the histologists. It is possible, too, that the adrenal sex effect is indirect through the medium, or with the coöperation, of the thyroid or pituitary. Polyglandular speculations are, however, premature. What is needed is the most careful and detailed investigation of such examples as may be discovered of the disease: in it medicine has made a most important contribution to the general biology of sex, and further study will no doubt illuminate much of what is at present obscure.

SILICOSIS IN DERBYSHIRE.

THE Derbyshire annual health report contains an interesting appendix on silicosis in the county by Dr. Patrick Hefferman, the tuberculosis officer. He defines silicosis as "a progressive fibrotic change in the lung tissue, due to the inhalation and deposition in the lung parenchyma of fine particles of silica, leading to the destruction of the functioning lung substance and its replacement by fibrous tissue. It is characterised, clinically, by steadily increasing dyspnœa, and by a tendency to develop and succumb rapidly to pulmonary tuberculosis in late middle life." Until quite recently the sharp spicules of silica were supposed to act by mechanical cutting effect. It is now established, he says, that the action is mainly a biochemical one, and that the silica particles, after being converted into a colloidal state, destroy the resistance of the lung tissue against the tubercle bacillus. Dr. Hefferman shows that the two most dangerous rocks in Derbyshire are the millstone grit and the ganister, both of which contain about 95 per cent. of free silica. Flint and chert are other rocks which consist chiefly of free silica and also concern Derbyshire industries. Chert, however, is only quarried in Derbyshire, and the greater part of the danger to workers is transferred to the potteries, where it is ground into fine powder. Flint from Northern France is used for the manufacture of white sanitary and table ware in the south of the county, and cases of silicosis due to this industry have been recorded at Burton dispensary. A fifth material dealt with in Dr. Hefferman's report is silica sand, which is found in pockets on the limestone plateau of West Derbyshire, and is used for brickmaking in the Bakewell district. Under the Workmen's Compensation (Silicosis) Act of 1918 the workmen in industries involving a risk of silicosis have to be examined annually and to be suspended from work and compensated if found to be suffering from silicosis or tuberculosis. Dr. Hefferman lays great stress on the paradox that "the grit-stone cutters, the traditional victims of the 'stonemason's disease,' remain outside the Silicosis Compensation Scheme, while the pocket silica sand brickmakers, with their low phthisis death-rate and their comparative freedom from silicosis, have been brought within the ambit of its provisions." The statistics collected by the late Dr. Sidney Barwise for the ten years 1901–10 demonstrate the very high death-rate from phthisis among the grit-stone workers. During the period 1910–20 there are indications of some improvement, although the mortality is still very high. On the other hand, Dr. Hefferman shows that, according to the popular belief, silica brickmaking is a healthy trade. In confirmation he has only been able to find one death of a silica brickmaker from phthisis during 1910–20 among 160 employed in the Bakewell district, whereas during the same period among about 350 grit-stone workers he found 19 deaths from phthisis, eight from pulmonary fibrosis, and one from hæmoptysis. His dispensary records have also shown that the cases of silicosis which occur among the brickmakers are nearly all in persons who have formerly worked as grit-stone dressers or quarrymen. The reason why pocket silica sand is less likely to cause silicosis than are grit-stone, ganister, flint, or chert is because each particle of silica is enveloped in a coat of clayey material. There are many suggestions as to how the clay acts as a

protection to the workers exposed to the dust, but one thing appears to be clear, that the presence of clay to the extent of 15 per cent. and of micacious matter to the extent of 7 per cent. reduce the amount of free silica in this sand to under 80 per cent.—the line of safety laid down by the Home Office. Dr. Hefferman suggests that more research is needed in this subject, and that if workmen cannot be protected from the inhalation of the dust, the treatment of the silicious material with a clayey substance may be useful. It is already recognised that the admixture of coal with the silica dust has a protective influence. We learn from the report itself that in 1925 the examination of workmen under the silicosis scheme was taken out of the hands of the tuberculosis officers and handed over to two whole-time medical officials specially appointed by the Home Office. Newly engaged workers, however, are still medically examined during the first month of their employment by the tuberculosis officers. The conditions of work and the nature of the dust in the atmosphere are also matters for the Home Office, whilst the occurrence of respiratory diseases, the clinical and radiographic records, and vital statistics are matters for the local health department and the Ministry of Health. Instead of getting nearer to the unification expected when the Ministry of Health was established, we seem in some ways to be getting further away from it.

ETHER CONVULSIONS.

THE occurrence of convulsions during the inhalation of ether was brought into prominence by an article contributed a few months ago to our columns[1] by Dr. S. R. Wilson, of Manchester, whose subsequent tragic death, while experimenting on himself with anæsthetics, has lent an added interest to the problems which he stated, although, it has also sensibly diminished the chances of bringing them to a definite solution. Convulsive muscular contractions during anæsthesia may be of various kinds, and before we can hope to determine the cause of the phenomenon in cases such as those cited by Wilson we must clear the ground by ruling out the categories of convulsion to which these almost certainly did not belong. Broadly speaking, there may appear in a subject under ether narcosis (1) fine tremors; (2) clonic contractions associated with alterations or peculiarities of position, common, for example, when the patient is quickly put into the lithotomy position; (3) convulsive movements associated with slight or with severe anoxæmic states. These are often most marked in the muscles of the face when the anoxæmia is slight, but they may violently affect the limb muscles as well as those of the trunk. When we are dealing with the observations of so experienced an anæsthetist as Wilson we may assume that the convulsions he described belonged to none of the three kinds just enumerated. If so this would rule out the explanation put forward[2] by Dr. J. T. Gwathmey, that the convulsions were the result of perivascular œdema and the accumulation of œdematous fluid in the alveoli of patients in whom ether has been administered without previous medication. The converse suggestion[3] made by Dr. R. W. Hornabrook, of Melbourne, that the convulsions were due to overdosage with atropine is rendered unlikely by the very large experience of preliminary atropine dosage without untoward event quoted[4] by Dr. H. Sington. In the same journal appears a letter from Mr. H. E. G. Boyle which bears upon the explanation maintained by Wilson himself; Wilson believed that the convulsions he described were due to impurities in the ether. Moreover, he showed how certain modern methods of using ether were prone to the formation of impurities in ether originally pure. Now comes Mr. Boyle's corroborative evidence that aldehydes and peroxides can be formed in good ether when nitrous oxide or oxygen or both are bubbled through it. It is to be noted, however, that the passage must continue for an hour or so and that the percentages of peroxide and of aldehyde found never exceeded 1 in 50,000 and 1 in 80,000 respectively. Wesley Bourne has shown experimentally that even ½ per cent. of aldehyde produces only an insignificant effect, although inhaled for as long as three hours, and that with peroxides the percentage must reach something like 0·5 per cent. for effects to be anything but negligible. If, therefore, we are to accept Wilson's explanation we must assume that the impurities reached a remarkably high degree, or else that the condition of the patients rendered them unusually susceptible to the action of the impurities present. It is noteworthy that the patients whose fatal cases were related by Wilson were all the subjects of acute septic disturbance. This does not apply, however, to examples brought forward by other observers, or to the milder instances in Wilson's experience. We cannot, in fact, declare that the occurrence of convulsions during ether anæsthesia, not occasioned by anoxæmia and terminating fatally, is as yet satisfactorily accounted for. It is obvious, however, that to use pure ether and to keep it pure is a measure of safety, and it is something to have arrived at this certainty and to have disposed of the mistaken advocacy of certain impurities in ether which was rife only a few years ago.

URINARY NEUROSES.

IN a lecture published in *Medizinische Klinik* of Sept. 9th, Dr. J. J. Stutzin (Berlin) declares that a neurosis as such has nothing in common with a disease of the neuron or nerve. To obtain insight into the meaning and cause of the neurosis he takes the conception of an unresolved conflict with a consequent flight into illness, a conception which assumes the validity of certain psycho-analytical generalisations. With regard to organ-neuroses, he asks whether there is a specificity, by which a conflict of a certain kind finds expression in a certain organ, or whether the incidence of the neurosis is a matter of chance. He answers that anxiety, for example, tends to show itself in the form of increased peristalsis—he might have added in the form of palpitation and tachycardia—whilst disgust appears as vomiting; but repeated treatment of an organ can "neurotise" it, and in some personalities a specific organ-neurosis can be masked by the general neurosis or the neurosis can pass from one organ to another. Stomach, bowel, and heart neuroses are commonly described, but kidney neuroses find little mention, though Stutzin gives a few references to experiments showing the influence of emotion upon urinary secretion and describes a case, tentatively diagnosed as renal stone, in which an emotional state during cystoscopic examination was accompanied by painful acceleration of ureteric action which disappeared when the patient was pacified and engaged in conversation. The symptoms were judged to be psychogenic and treatment by psychotherapy proved successful. Among other cases described is one in which the patient had been operated upon for suspected renal stone, then for suspected gall-stone, and only when he demanded appendicectomy was he examined "neurologically" and found to be a psychoneurotic repressed subject who unconsciously sought a pleasure-equivalent in operations. Bladder incontinence or retention, originally neurotic, may be converted into cystitis by instrumental interference, and, on the other hand, post-gonorrhœal symptoms of disabling severity with associated suicidal ideas were abolished by an exploratory puncture of the testicle and the incision of a subsequent scrotal hæmatoma. This unexpected therapeutic success was excelled in the case of a man of 60, diabetic and with severe myocarditis, upon whom Steinach's rejuvenation operation was attempted under local anæsthesia. The incision of the skin caused such a severe shock that the operation was abandoned, but the failure was followed by a return of sexual vigour and enterprise, of an erect poise and

brisk gait, whilst after some weeks the man declared that his hair had become black; his wife endured a plastic operation upon the face in order to keep level with him.

Dr. Stutzin's paper draws together a number of clinical observations that can be paralleled in the experience of many genito-urinary surgeons, and he does good service in directing attention to the existence of these neuroses, which are so liable to pass unsuspected. A reference to the departed vogue of operation upon movable kidneys in neurotic patients would have added historical interest and pointed a moral. Taking a general view, he concludes by noting that we are turning aside from our over-estimation of laboratory results, but that much remains to be done before we shall be in a position to treat neurotic patients systematically, whether by suggestion or analysis.

THE CLINICAL USE OF IRRADIATED ERGOSTEROL.

WE have recently [1] commented on the discovery that irradiation of ergosterol provides vitamin D in a state of high concentration. This discovery has already been applied in clinical practice, and the *Deutsche Medizinische Wochenschrift* of Sept. 9th contains an interesting group of papers on the use of irradiated ergosterol in the treatment of rickets, late rickets, and osteomalacia. In most cases the dose given daily was from 2–4 mg., following the example of P. György[2] and of H. Beumer and C. Falkenheim,[3] but in one case as much as 10 mg. was given without any detrimental result. O. Rosenheim and T. A. Webster[4] point out that in the rat it does no harm to give a dose many times greater than the minimal effective dose, and this is evidently true for human beings, since calculating roughly by body-weight, compared with a rat, a dose of 2–3 mg. should be some hundreds of times larger than the minimal dose needed for an infant. The ergosterol was usually administered as a solution in olive oil, but cocoa-butter pastilles and sugar-coated tablets also gave satisfactory results. A. Hottinger reports that he cured a child under one year with 1 mg. daily, and children over a year with 2–3 mg. He also cured a young man with late rickets and a woman of 35 with recent osteomalacia with 3 mg., and two older women with severe long-standing osteomalacia with 5 mg. daily. C. Falkenheim had remarkable success with doses of 3–5 mg. in treating rickety children with severe complications such as broncho-pneumonia. He received the impression that the prognosis of the complications was greatly improved when the rickets was thus treated. He found X ray evidence of bone healing, even when the level of calcium and phosphorus in the serum remained unaltered as a result, he considered, of the complicating illness. W. Lasch and A. Behrens state that they cured rickets in five infants—which had developed the disease before their eyes in their own infants' home—with daily doses of 3–4 mg. of irradiated ergosterol. They think that the substance has a great future as a prophylactic, as its use obviates the loss of the mother's time involved in bringing her child for direct irradiation with ultra-violet light, whilst it has not the nauseating qualities attributed to cod-liver oil. W. Starlinger describes a striking cure, with 10 mg. daily, of a woman with osteomalacia. After three attacks in successful pregnancies she had become a complete invalid after the fourth pregnancy, and since 1919 had only been able to walk with the greatest difficulty. She had received a variety of treatment, including removal of the ovaries. After 12 days' treatment with irradiated ergosterol she suddenly began to improve, and after 20 days began to walk and progressed steadily thereafter. This group of papers is a useful instalment of clinical experience from Germany and Switzerland, and goes some way to demonstrate that irradiated ergosterol is as reliable an antirachitic agent as ultra-violet light or cod-liver oil, and in many ways a more convenient one.

THE WEARING OF A TRUSS.

IN another column a correspondent, who signs himself "Senex," writes of the sorrows of the wearer of an imperfectly fitting truss. From the wealth of his own experience he talks quite frankly of the failure of the appliances provided to effect their object, due in his opinion to the lack of coöperation between surgeon and mechanician, and he comments on the lack of any hospital for hernia even in London and of the non-existence of surgeons specialising in the mechanics of the truss. There is, we must admit, more than a modicum of truth in our correspondent's criticism. Certainly at the City of London Truss Society the surgeons in charge personally fit the truss, of whose construction they have a real and intimate knowledge, but it is doubtful whether at the majority of medical schools even in London there is any consistent and definite teaching of the principles of truss-fitting, and in the case of the surgical aid societies it is the practice of the surgical staff simply to send their patients on to an instrument maker. The position is, in fact, analogous to that of the fitting of artificial limbs where, except at Roehampton, the instrument maker is in charge. At Roehampton, of course, it is the special limb-fitting surgeon who prescribes the limb, sees to its fitting at the various stages, and passes it when finished, with the result that nowhere in the world has limb-fitting reached such a high level. The time has probably come when the University of London might be asked to have a series of lecture-demonstrations on limb-fitting by the Roehampton staff. It seems clear that the principles of truss-construction and truss-fitting should be taught in every medical school, and if the demand should arise for a definite course of instruction on the part of newly qualified practitioners, no doubt the surgical staff at the Truss Society would be glad to arrange for post-graduate instruction. The matter is evidently worthy of closer study by educational authorities.

THE TAPEWORM'S HEAD.

THE treatment of tapeworm is useless if the head of the worm is not expelled. The starvation and purgation involved are exhausting to the patient, and if the first few attempts fail he is likely to continue his hospitality indefinitely rather than submit to further efforts to expel his guest. It is important, therefore, to get rid of the head at the first attempt. In a recent paper [1] Dr. T. B. Magath and Dr. P. W. Brown discuss the difficulties of treating tapeworm successfully, and describe a routine which they have found successful. The patient should not take dinner or supper the day before treatment, but black coffee, tea, and water may be drunk freely. At 6 P.M. and again at 6 A.M. 15–30 g. of magnesium sulphate are given. No breakfast is allowed, but after the bowels have been opened 30 c.cm. of the following emulsion is administered: oleoresin of aspidium, 6 c.cm.; powdered acacia, 8 g.; distilled water to make 60 c.cm. One hour later a second dose of 30 c.cm. is given. After two hours 30 g. of magnesium sulphate are again given, and two hours later a large soap-and-water enema. The patient then passes a stool which is sent straight for examination. The top watery part may be poured off and the rest is passed through a sieve with a 20-mesh bottom. The contents of the sieve, which are now chiefly worm, are emptied into a flat enamel pan, the bottom of which has been painted black, and the head is looked for. As a result of this treatment the head was recovered in 10 out of 19 cases at the first attempt, and in two others at the second. The seven failures were due to patients vomiting the drug or to contamination of the stool with food débris.

[1] Jour. Amer. Med. Assoc., May 14th, p. 1548.

In particular, it is stated, fruit should be avoided before the treatment. If the drug is vomited it may be given by a stomach-tube. Castor oil must not be given as a purgative, for aspidium is soluble in it and is then highly toxic. This routine, in the authors' hands, certainly seems to give more successful results than those usually obtained. They point out that to give an enema at the end is extremely important, for often when the worm is dislodged the head breaks off and passes into the colon, where it remains unless swept out by a large enema.

EXTRAMEDULLARY BLOOD-FORMATION.

ANÆMIA is very common in infancy, partly because an infant's blood is especially vulnerable to the toxins of such diseases as gastro-enteritis, rickets, and syphilis, and partly because children have a relatively small reserve power of blood regeneration. Their tissues have not only to produce blood for the support of the organism, but also for its growth. Any extra strain upon them is shown by the appearance in the blood of embryonic cells which in the adult would be seen only in very severe stimulation or disease of the bone-marrow, and this makes the anæmias of infancy more difficult to classify than those of later life. For some time after birth, although the bone-marrow is the chief blood-forming organ, other tissues have considerable power of reverting to their fœtal power of blood-formation when called upon to do so. In the August number of the *Bulletin* of Johns Hopkins Hospital Dr. Dorsey Brannan discusses this question of extramedullary hæmatopoiesis and quotes many cases from the literature described under the names of von Jaksch's anæmia, pseudoleukæmia infantum, splenic anæmia, and pernicious anæmia of infants, in which autopsy revealed tumour-like growths of hæmatopoietic tissue outside the bone-marrow. In a case under his own observation the child was 7 months old and had a large liver and spleen associated with rickets and malnutrition. The blood showed anæmia of a secondary type with a great number of normoblasts and early myeloid cells, together with a few megaloblasts. Post mortem he found red tumour-like growths filling the hiluses of the kidneys and abundant red tissue covering the falx cerebri, these growths being composed of all the elements of hyperplastic bone-marrow with a great preponderance of erythrocytic cells. There was similar tissue in the thymus and lymph nodes, but the spleen and liver, both large and fibrosed, showed little evidence of blood-formation. Dr. Brannan also describes foci of blood-forming tissue in the broad ligaments and breasts of other children not suffering from anæmia, and a case of severe anæmia secondary to uterine sepsis and hæmorrhage in a woman of 27, in which evidence of extramedullary blood-formation was found in the liver, spleen, and broad ligaments. He considers that such growths of hæmatopoietic tissue are fairly common in some of the anæmias of infancy, and that they are the result of compensatory stimulation. They occur most often in the hilus of the kidney, but also in the broad ligament and in the breast.

WE regret to announce the death on Oct. 4th of Mr. Henry Brunton Angus, Emeritus Professor of Surgery in the Newcastle College of Medicine, University of Durham.

THE personal friends and colleagues of the late Prof. Adrian Stokes have decided to establish a permanent memorial to him. Its precise character will depend upon the funds which become available, but the object will be to endow medical research in some way. His personal friends are convinced that the establishment of a Stokes Memorial Fellowship or Studentship is the only type of memorial of which he would himself have approved. The funds will be controlled by Guy's Hospital Medical School, and subscriptions should be sent to the Dean.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXLIV.—THE TREATMENT OF INSOMNIA.[1]

II.—THERAPEUTIC MEASURES.

1. *Physiogenic Insomnia.*

THE treatment of insomnia dependent upon definite physical disorder is, in general, that of the associated disease, and most of the conditions are outside the scope of this communication. Continued pain, however, due to neuritis or neuralgia and resulting in protracted insomnia in unstable individuals may, if unrelieved, lead to a psychoneurosis or even a psychosis. Cases are not uncommon where the organic disorder having ceased to exist, both the pain and insomnia persist as hysterical manifestations. In the sleeplessness caused by definite pain analgesic drugs are indicated, such as acetyl-salicylic acid (5–15 gr.), pyramidon (4–8 gr.), veramon (2–3 tablets), novalgin (7½–15 gr.), or dialacetin (½–2 tablets); the latter is a most useful drug for pain combined with insomnia. If the pain is of a severe and temporary character morphine or the total alkaloid preparations, opoidine (⅓ gr.) or omnopon (up to ¼ gr.), may be indicated.

In all patients who complain only of sleeplessness, in whom no obvious physical cause can be found, it is as well for the practitioner to make quite sure at the outset that the symptom is not one of physiogenic origin. Dyspepsia and constipation as causes of insomnia may easily be overlooked; flatulence especially is liable to lead to delayed sleep. It is often worth while to try the effect of a carminative draught taken at bedtime. Minor circulatory disturbances—e.g., cold feet—may also be missed. In cases of high blood pressure the treatment is largely that of arterio-sclerosis—dietetic measures, moderate exercise, saline purgatives, and iodides. A dose of nitroglycerine at night is often helpful.

2. *Psychogenic Insomnia.*

Where the cause of the sleeplessness is of psychical origin the practitioner's first step, as already stated, is to ascertain all possible causes of mental discomfort—anxieties, &c. Elucidation of the mental factors, however, may take a considerable time, and prolonged psychological investigation and even psycho-analysis may be necessary; in the meantime the patient needs sleep. Much help can be given by trying to persuade him to adopt the right mental attitude to his symptom. Those who suffer from insomnia almost always exaggerate in their own minds the severe consequences of not sleeping adequately, a fact which adds considerably to their anxiety. The physician should point out to the patient that there is no fear of his losing his reason or dying as a result of his sleeplessness, that a smaller amount of sleep than most people take is quite compatible with health, and that rest in bed with muscular relaxation is to a certain extent a substitute for sleep. A correct mental attitude will assist greatly in relieving an anxiety state and combating insomnia; delayed sleep is often kept up by worry concerning it, the patient going to bed anticipating and dreading that he will not fall asleep. On the other hand, it is useless for him to try to make desperate efforts to go to sleep; as far as possible he should retire to bed in a tranquil state of mind, believing that sleep will come. Failing this, if he can be persuaded to show indifference to sleep, the insomnia will sometimes disappear.

In the subject of insomnia every effort must be made to raise the level of the general health by

[1] The first section of this article—General Considerations—appeared in last week's issue.

suitable feeding, warmth, and judicious exercise; the tendency to undue fatigue must be counteracted by a reduction of the daytime activities and the taking of short periods of rest, especially after meals. Cerebral excitants, such as coffee and tea, are best avoided in the latter part of the day. As sleep in many individuals is largely a question of habit, the patient should retire to bed at a regular hour each night and should avoid close mental work during the evening, or if this is impossible, he should take a short walk before bedtime. A warm bath promotes sleep in some cases, but has the reverse effect in others; it is, however, worthy of trial. In those who suffer from cold feet, a hot mustard foot-bath at bedtime is often helpful. It is unwise to go to bed on an entirely empty stomach, since it is generally accepted by physiologists that cerebral anæmia plays some part in the mechanism of sleep. A meal tends to produce drowsiness, blood being required in the splanchnic area for purposes of digestion, and this leads to a corresponding diminution in cerebral vascularity (compare the desire of most animals to sleep following a meal). For this purpose it is advisable to take warm soup, bovril, or cocoa with dry biscuits half an hour before bedtime.

The patient should have a bedroom to himself, which must be dark, quiet, and well ventilated. All clocks must be removed and the light turned off; if, however, the latter is impossible owing to the patient's apprehension, the light must be subdued by shading. A spring mattress is usually best, but much depends on that to which the patient has been accustomed. The bedclothes should not exceed the minimum quantity required for comfortable warmth, and in those sensitive to cold the bed must be warmed with hot-water bottles after a through airing in the daytime. As regards posture, it is generally preferable to try to sleep on the right side; in this position pressure by the liver on the stomach is avoided and it is easier for the latter organ to empty. The height of the pillow will depend largely upon the patient's habit, but in cases of increased blood pressure a high pillow is desirable.

Reading in bed sometimes promotes sleep, and some individuals habitually read until drowsiness compels them to extinguish the light. Unless the patient is accustomed to "read himself to sleep," it is best not to introduce the suggestion in case a habit of wakefulness be established.

Education in complete muscular relaxation is sometimes valuable. The faculty of muscular relaxation can be so developed that the patient is able to relax all muscles upon getting into bed, a habit that greatly favours the onset of sleep. General massage, with special attention to the spinal muscles, carried out shortly before the usual hour of sleep, is of great assistance, especially in cases of neurasthenia.

As regards alcohol, much again depends upon the patient's habits and how he reacts to alcohol. Stout or a glass of hot whisky and water at night will induce sleep in many individuals when everything else has failed; in others, however, it has but a temporary effect and may even cause wakefulness.

As suggestion—the hour of day, undressing, and the accustomed bedroom—probably plays a considerable part in the production of sleep in adults, it is generally best to try to treat insomnia in the patient's own home. In cases of long standing, however, a change of environment is usually desirable. The bedroom and surroundings may have lost their suggestive effect, and far from inviting sleep, actually repel it by the association of continuous nights of wakefulness. In the extremely rare cases of insomnia due to overwork in the absence of associated worry, or in which the anxiety is of a superficial character, a holiday may speedily effect a cure.

Hypnosis has often been advocated in the treatment of insomnia. In the writer's experience neither simple suggestion without hypnosis nor post-hypnotic suggestion is very satisfactory. In suggestible subjects a temporarily good result may sometimes be obtained, but even such cases quickly relapse in the absence of more radical treatment. In other cases no effect is observed.

Cases in which the sleeplessness is of long standing and has resisted the simpler methods of treatment described, as well as those in which the symptom amounts almost to an obsession, will usually require deeper and more prolonged psychological investigation—psycho-analysis or one of its modifications—to obtain a satisfactory result. In such cases the younger the subject the better the prognosis, while after middle age psycho-analytical methods are unlikely to benefit.

It is almost needless to state that it is far better to treat the cause of insomnia rather than the symptom of insomnia itself. In psychogenic cases, however, this may occupy a considerable period, and in the meantime, pending the result of psycho-therapeutic and other measures, the patient must have sleep. Although the routine use of hypnotics is indicated only in exceptional cases, it is unjustifiable to withhold such sedatives owing to the often groundless fear of habit-formation on the part of the patient; the insomnia, indeed, is far more likely to become a fixed habit and the patient is usually only too glad to discard the hypnotic. Also, in many cases, if sleep be induced even by artificial means, a definite psychosis may be averted.

Hypnotics.

In prescribing a hypnotic one cannot afford to fail, since the patient may be left in a worse condition than before; consequently, it is wise to begin with a substance and a dose a little stronger than is really necessary. In mild cases simple bromides or "sedobrol" may be used, but the bromide-urea compounds—bromural (5–10 gr.) and adalin (10–15 gr.)—or dial (1½–3 gr.) are often more efficacious; the latter is very safe and sure and has no unpleasant after-effects. Of more potent sedatives, the veronal group — especially medinal (sodium-veronal) in 7–10 gr. doses—are very satisfactory; it has been shown that these drugs in *therapeutic* doses have no toxic effect upon metabolism and no cumulative action. Paraldehyde is too unpleasant for general use, but is helpful in alcoholic cases and in pneumonia, while chloralamide is too uncertain in its time of action. On account of its delayed effect trional (10–20 gr.) is indicated in internocturnal insomnia, in which the patient is awake only in the latter part of the night. Sulphonal (10–30 gr.) suits some individuals, but is generally inferior to veronal and medinal, while luminal in hypnotic doses is undesirable. Morphine should not be used in insomnia of psychogenic origin outside a mental hospital. In practice it is usually best not to continue a hypnotic longer than two or three weeks without an attempt at a gradual reduction in the dose employed. In the later stages, with the patient improving, the sedative may be varied from time to time, with a slight reduction in dosage on each occasion a hypnotic previously used is again prescribed. A hypnotic by the bedside of the patient to take if necessary is often successful and he may sleep night after night without needing it.

In the acute psychoses of which sleeplessness is so common a symptom, the use of powerful sedatives (the so-called "chemical restraint") is becoming regarded with increasing disfavour. Endeavours are being more and more directed towards assisting nature to bring about relief by careful nursing and general treatment—attention to the digestive and excretory functions, frequent baths, and the administration of alkalis. Attempts to promote sleep are also made by warm sponging, hot packs, and continuous baths. Hypnotics, nevertheless, are often necessary but should be used judiciously and as sparingly as possible.

C. WORSTER-DROUGHT, M.D. Camb., M.R.C.P. Lond.
Physician, West End Hospital for Diseases of the Nervous System; Lecturer in Neurology, Bethlem Royal Hospital.

Opening of the Medical Schools.

THE MEANING AND METHODS OF SUCCESS.

An Address (Abridged) delivered to Students of St. George's Hospital on Oct. 1st, 1927,

BY SIR HUMPHRY ROLLESTON, BART., K.C.B.,
REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE.

EVERYONE at some time or another must ask himself the questions whether or not and how he can attain success; these problems, though visualised, should not weigh too heavily or constantly on the mind, for sufficient to the day is the burden thereof, and if this is well borne the future may be trusted to look after itself. No one, however confident or diffident, can tell what is in store for him or command success, but he can do better by deserving it. The vagaries of blind fortune, the chances of injury and illness, and more particularly the student's character still in process of formation, as much or more than ability and industry, are in the main the determining factors.

The average student is usually too busy with hard work and healthy play to think much beyond the goal of passing his examinations so as to be able to earn a living, or, if an old-fashioned hero-worshipper and vaguely ambitious, of following in the steps of a teacher; it is therefore perhaps not surprising if he seldom stops to analyse solemnly what exactly constitutes success. Yet surely it is desirable for his present guidance to formulate some conception of his ideal of a medical life.

Estimates of success have been made by Sir James Paget (1869), Sir Squire Sprigge (1906), and Mr. E. Corner (1920) on the basis of the only available material data—namely, attaining certain positions in hospital and private practice. These statistics brought out at different times are satisfactory, for they show that on an average 75 per cent. of medical students qualify, and that of those who start in practice 66 per cent. have reason to feel justified with their choice. But apart from freedom from anxiety about the means necessary to provide for dependents and to live in fair comfort, what are the essentials of a right conception of success in medical life?

Forms of Success.

There are many kinds of what may be called success—the fashionable and financial, the intra-professional, the scientific and intellectual, and the humanitarian. The obvious hall-marks of success in the popular view are, of course, a large income and a title; in all walks of life these certainly point to achievement and must not be gainsaid or their value minimised. But they may be and often are due more to commercial astuteness than to those finer qualities of sympathetic imagination and unselfish wisdom which go to make up the character of the ideal healer. It must not, however, be assumed that the combination of the best success is incompatible with, or so often divorced from, the financial as those without experience of either may believe.

Another and a potentially wider conception of success is to get what you want, be that what it may—riches, fame, affection, troops of friends, so that all men speak well of you. But as this, like the previous form of vaulting ambition, may in George Moore's words, become

> "Like Dead Sea fruits, that tempt the eye
> But turn to ashes on the lips,"

and, bearing in mind Oscar Wilde's epigram that "there are two great tragedies in life, not getting what you want—and getting it," the definition should be expanded into that given by Osler, "getting what you want and being satisfied with it." Many agree with Robert Louis Stevenson that "To travel hopefully is better than to arrive, and the true success is in labour."

A high ideal is to make some great discovery or reform that permanently benefits mankind, to relieve, or preferably prevent, human suffering, and so to leave the world better than it was before. Some of these original investigators, inventors, and reformers have not been properly recognised during their lifetime and so, because the world was not then ready for them, must have appeared to be failures, but—

> "Not all who seem to fail have failed indeed,
> Not all who fail have therefore worked in vain,
> For all our acts to many issues lead."
> —*M. I. Fortescue-Brickdale.*

This most enviable ability for original discovery is given to few, but there is another form of success within the reach of ordinary mortals, not indeed as the outside world understands and uses the word, but from the individual's own point of view: it is to preserve your own peace of mind and respect by the consciousness of honest work well done, and duty carried out without fear or favour, in making others better and happier in body and mind, and by freedom from discomfort and regrets for any action mean and contrary to the golden rule to "do unto others as you would they should do unto you."

Methods of Attaining Success.

To follow the wrong profession is a tragedy and a sure bid for unhappiness and failure. But when what seems to be the right choice has been made, what are the further essentials? Obviously to start with, as in other professions, a thorough knowledge of the science and art—the two Janus-like faces—of medicine; and not only this, but to remain throughout life students, ever on the look-out to observe and learn, for there is no trace of finality about medicine, especially in these days.

Mental ability alone is not sufficient, though it goes a considerable way towards professional success. "A physician," said Osler, "may possess the science of Harvey and the art of Sydenham, and yet there may be lacking in him those finer qualities of heart and head which count for so much in life." Peter Mere Latham, one of the great clinical physicians a century ago, when our science and art were infinitely less detailed and specialised than now, wrote:—

> "Knowledge may be an incumbrance as well as a help. Many men know more than they are able to wield. There is a point (I believe) in the acquisition of knowledge (and this point varies infinitely in different individuals) beyond which, if more be acquired, the whole mass becomes useless to its possessor. I am acquainted with men who never have *done*, and never can do anything, because they know too much; and I am acquainted with men possessing comparatively small knowledge, so dexterous in its use that they have ridden over the heads of others far, very far, their superiors in acquirements."

Though reading maketh a full man, too much may induce mental dyspepsia, breed excessive obedience to authority, and so destroy any originality and independent thought. Read we should, but let it be methodical, with discretion, and accompanied by critical analysis and digestion, so that the state of the stuffed Strasbourg goose be not the result. As a practical method of analysis, a written abstract made at the time serves a double purpose; not only does it impress the details on the tablets of the mind much more effectively than mechanically underlining the book when sitting in an easy chair, but is most useful for future revision. It is a common mistake to measure the amount of work by the clock; the real criterion is not the number of hours spent, but the degree of concentration brought to bear on the subject. Concentration produces the greatest effect in the minimum time and is the economical secret of the successful and busy man.

There are in addition other factors to be considered, especially a knowledge of men and womenkind which is so important in the treatment of the sick. Though, like most epigrams, that to the effect that "one-quarter of savoir and three-quarters of savoir-faire make the successful practitioner" may be an exaggeration

there can be no doubt of the value of the personal equation in gaining the confidence of patients, their relations, and professional brethren. A man should, of course, have the requisite professional knowledge, but he must be able to make full use of his acquirements. This necessary personality is not shown by a bedside manner with a suggestion of pompous superiority; it is the result of getting inside the patients' minds so as to think their thoughts, feel their feelings, and thus understand their mentality and anxieties so thoroughly that the medical man is obviously their friend with their interests so entirely at heart that nothing else counts. This is not an actor's mask, but the outward and visible expression of true charity and forgetfulness of self. I would like to subscribe to the following from an address given by my father in 1874, when distributing the prizes at St. Mary's Hospital Medical School:—

"I believe that the rule 'put yourself in his place,' based on what modern philosophers call the principle of altruism, but what is found expressed plainly enough in much older language than theirs, is the rule which, if I were confined to the choice of one single guiding maxim to be given to a young doctor just entering upon the responsibilities of practice, I should choose for that maxim. Sympathy is truly called a divine gift, and it does assuredly give a superhuman power. I presuppose, of course, patience in investigation and carefulness in ratiocination; but such is often the obscurity, intricacy, and complexity of a medical problem, that in the ultimate resort, it is upon intuition rather than upon syllogism that its true solution depends. It is to the man who has the touch of genius, that strength of imagination, which enables him to put himself in the patient's place and thus do full justice to him that there 'ariseth up light in the darkness.' It is for want of all this that 'great men are not always wise.'"

The faculty of inspiring confidence, like the love of children and dogs, may be inborn, for there undoubtedly are men highly esteemed and of acknowledged ability but whom none of their friends think of employing professionally. A want of appreciation of his patients' state of mind, which is naturally focused on their ailments, may allow the doctor to discourse on his hobbies and private interests; whereas from his patients' point of view his raison d'être is solely to discuss their urgent needs. No doubt attempts to distract them from themselves have their place and value, but the time for this is after, not before, a full, often it must be admitted tedious, hearing and consideration of their troubles so as to unburden their minds and ensure complete satisfaction. In doing this there must be calmness without coldness, decision without dour dogmatism, friendliness but firmness. It may be difficult to steer between saying too little and talking too much, and while avoiding garrulousness there is the temptation to imitate those who by a sententious or somewhat cryptic phrase get out of a difficult situation for the time, but seldom satisfy their patients' wants. Honesty and truth are essential, but what may at the time seem the whole truth should not always, in the light of human fallibility and his best interests, be communicated to the patient. In making mistakes, as inevitably all must do, it is always better to err on the side of optimism than of pessimism. It was said of the late Sir William Osler that "he never left a sick-room without leaving behind renewed hope."

Relations with other medical men, popularly spoken of by the layman as medical etiquette or ethics, with a thinly disguised dislike and a suspicion of a mysterious trade-unionism, are in reality a very simple matter—obedience to the golden rule of treating other colleagues as we would wish them to treat us. In carrying out this elementary principle there is nothing more obvious than total abstinence from adverse criticism of other medical men. Before judging of what another medical man is reported to have done or said it is instructive to bear in mind how rumour may transform your own actions and remarks out of all recognition.

Importance of Good Health.

Almost as important as common sense and a sympathetic and healthy mind are good health and physique to withstand the strain of hard, continuous work. Doctors should not only advise, but in their own interests set a practical example in personal hygiene, proper recreation, exercise, and holidays in spite of the numerous difficulties that surround them. From insomnia, headaches, and dyspepsia born of irregular and hasty meals a man may become angular, forgetful, and deficient in the qualities which make for his success with trying patients. On the other hand, great things have been accomplished by medical men crippled or physically handicapped in one way or another; incapacity in one respect may, by compensation and concentration, result in a high degree of excellence in another direction.

Terence's line, *Homo sum; humani nihil a me alienum puto*, applies most certainly to our humanitarian calling; but although wide culture, literary activities, and hobbies are good for the soul, these are for private use and not for parade. There is widespread belief, often no doubt erroneous, that a man cannot excel in more than one line, and so when a doctor is known, for example, as a writer of verses, most people are inclined to consider him too good a poet to be their common-sense guide, philosopher, and friend in unromantic medical matters.

THE DOCTOR'S HIGH CALLING.

Being part of an Address to Students of the London School of Medicine for Women on Oct. 3rd, 1927,

BY R. G. HOGARTH, C.B.E., LL.D., F.R.C.S.,
LATE PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION.

AN exclusively scientific training often leaves something to be desired in the way of mellowness and ripeness, and the professional man or woman of to-day suffers serious handicap unless his or her mind is well cultured, well garnished and sensitive to the impression of what the Greeks called "the beautiful." Energies should not be dispersed too widely, but narrowness must be avoided at all hazards. Medical text-books contain the rather arid knowledge indispensable for the satisfaction of examiners, but they are markedly deficient in the attractive graces, the freshness and the inspiration to be found in the best poets, essayists, and novelists. It is not enough for the woman doctor to be distinguished in the street by her spectacles, by her shoes, or by the attaché case in which she carries her instruments. Apart from her professional skill, she should be known by her culture, by her judgment and discernment, by her greater detachment from the idols of the market-place, and by that sure way of approaching a question at issue which is the hall-mark of the trained and balanced mind.

This is a golden moment at which to begin the study of medicine. The only time, perhaps, when the prospects of those entering the profession in the spirit of scientific adventure or with a real enthusiasm for the welfare of their fellows were in any degree comparable with the present, was in the early days of Greek culture, when Hippocrates first disentangled medicine from priestcraft. Medical science was then launched under the fairest auspices and with the brightest hopes, and mankind never suffered a more grievous calamity than when it drifted into the shoals and quicksands from which it was only effectually rescued in recent times. Medicine returning once more to Nature, rejecting all methods save that of observation, and all interpretation save that of strict causation by natural causes, has now gloriously renewed itself. Sure of its direction, it looks forward with great confidence to an ultimate control of disease. The profession, moreover, possesses to a degree hitherto unknown, the general confidence of mankind. Men and women in all ages have run with anxious faces to the doctor in the hour of trouble; yet the keener wits were never deceived by the professional cloak of mystery with which he shrouded himself. The reason of the present marked change

from credulous incredulity to implicit confidence is to be found in two words—scientific method. The temple of healing has been rebuilt from its foundations. The fountains of pure water have been cleared from the rubbish of centuries, and through its porticos and halls blows the fresh clean air of free inquiry. Scientists have indeed been driven to invent a jargon of their own, because they need such a bewildering multitude of new words with exact and precise meaning. But there is still only one set of scientific principles, and even in the labyrinthine complexity of modern medicine there is a grand and austere simplicity. The world may be able to afford the luxury of several religions; it can only afford one science of medicine.

This is the age of scientific adventure, but we are not all discoverers, and in medicine, as in other professions, the majority belong to the rank and file, who do the everyday mending and patching of common humanity. A vast routine of ailment, slight and serious, runs with the sun its appointed course. Men and women obstinately continue to transgress the laws of health and, in spite of daily articles on diet, there need be no apprehensions of any lack of patients. It is told of old Dr. Abernethy, that on entering his lecture room on an occasion like the present and observing a large influx of new students, he threw up his hands and said: "Good God! what is to become of you all?" And even to-day the pessimists lament that there are not enough good jobs to go round. But such dismal forebodings should not be allowed to depress natural enthusiasm. In no profession, I believe, is there so high a percentage of those who make a fair success out of their practice. Some 60 years ago Sir James Paget estimated that of those who actually reached practice, 36 per cent. made a very fair success of it, meaning by that that they were able to maintain themselves as professional men in adequate style. I feel sure that the percentage has risen of recent years, and in a specially marked degree as a direct result of the National Health Insurance Act which has proved a very good friend to the general practitioner. The State to-day not merely recognises but earnestly realises its direct responsibility for the health of the people, and association of the profession with the State will increase and not diminish, opening out an ever-widening horizon of honourable and profitable employment.

No doubt the majority of you will join, not the noble army of martyrs to the cause of pure science, but what I may call the goodly fellowship of practising doctors and surgeons. You will find even here scope for the exercise of all the altruism in your composition. I do not wish to pitch the note too high. It would be fantastic to pretend that doctors are immune from the ordinary failings of humanity. But I do think that their calling brings into continual play their finer feelings and instincts, and that doctors are specially sensitive to the call of duty. The medical art can do much and will do more, and you may be sure that, as you grow grey in its service, you will see it held in ever-increasing honour.

THE PATHS TO THE STARS.

"Macte nova virtute puer; sic itur ad astra."

Abstract of an Address to Students of the Middlesex Hospital on Oct. 4th, 1927,

BY VICTOR BONNEY, M.S., F.R.C.S.,
ASSISTANT OBSTETRIC AND GYNÆCOLOGICAL SURGEON TO THE HOSPITAL.

YOU students are like men about to march into a vast and unknown country. We older ones are like observers in an aeroplane who can see tracks through the dense forests, fords across the deep rivers, and gaps in the sheer ranges, which are invisible to the explorers on the ground. Viewed from the height that experience and detachment give, the main routes to success seem clear enough, though whether the observer, placed on earth again, could find them is quite another matter.

To fight the battle of life each of us possesses a host of higher cerebral cells, on the measure of whose efficiency and the degree of determination with which they are put into action success depends. The number of these cells in different individuals probably varies very little, and I believe that their quality is also much the same—geniuses and congenital idiots excepted; so that the results attained depend largely on the number trained for and put into active service, and, above all, on the force of the initiative that keeps them at work. Interest in a thing to be done is the driving power that puts the intellect into action. If aroused for the thing's own sake we call it aspiration; if for what the accomplishment will bring, ambition, so that to succeed it is necessary either to aspire or to be ambitious, or, as I think most successful men have done, mix the two in such proportion as you are able. The fundamental secret of worldly success is perfectly summed up by Kipling:—

> "And they asked me how I did it, and I gave 'em the Scripture text,
> You keep your light so shining a little in front o' the next."

Now some of the obstacles to success may lie with Time, Circumstance, or Personality, and by their nature be unalterable. Of circumstances, poverty is often held to be the greatest handicap, but I believe that it is the commonest mainspring of success, for a healthy man hates work and only extends himself under considerable stimulation, and of all incentives an empty pocket is the greatest. To those of you who have to start so I say that your chances of achieving great success are about three times those of your more opulent classmates. Personality, again, is a factor over which the individual has little control. In this matter the odds are on the big man. Size gives an impression of solidity and dependability extending to the mental equipment. I have known men who did handsomely on size alone!

To achieve legitimate success in any profession the first necessity is high technical ability, and, therefore, he who wishes to rise to pre-eminence must train the larger proportion of his intellectual units for that end alone. But if anyone thinks that great technical ability *by itself* is the usual agent whereby a medical man attains outstanding success, reckoned on its vulgarly accepted criteria, I must disillusion him. Of the impediments you will encounter only a proportion are strictly professional. Foresight, tact, and judgment are qualities auxiliary to mere professional skill, and without them you are unlikely to win through. You must therefore avoid excessive professionalism, and, by mixing on their own plane with all sorts of people, learn the follies and greatnesses of human nature, so that you can put yourself in your patients' shoes. It is in general practice best of all that the great quality of sympathy is acquired, and the man of understanding comes to realise how much more scientific it is to treat the patient than merely the disease.

Technical excellence by itself, though it rarely brings great success as the world assesses it, will in time bring a fairly good, and incidentally an honest living. Pukka goods will find a market sooner or later, even though they be ill-presented and poorly advertised. It is, however, possible to allot too many intellectual units to the acquirement of worldly knowledge, so that that foresight and tact may degenerate into calculation and subtlety. It may, of course, be urged that the proportion of professional to non-professional qualities in a doctor's intellectual lay-out should, strictly speaking, depend upon the character of the persons with whom he will have to deal, and that the mind of one whose clientèle consisted solely of university professors would require to be differently organised from one who had to deal mainly with those delightful people who are the mainstay of our weekly pictorial press.

I would remind you that success is not merely a matter of getting to the front but of keeping there; so that having, so to speak, carried the position a

man must have sufficient troops left over to maintain it. Once entrenched, however, behind a big reputation, a relatively modest intellectual effort is sufficient to hold your ground; and this is the truer the more important and elevated the position you have captured. Of material honours and distinctions in any profession or calling, it is the first that needs striving for; the second is always more cheaply bought; whilst when it comes to the fifth or sixth, it seems to be only necessary to sit still under the flowing stream of favour, and the rest is automatic.

I have called this address the Paths to the Stars, for there are many constellations, and we do not all seek the same one. Some are relatively near, and hence shine very brightly; others are so far away that their incomparable radiance can only be seen with the eyes of strong faith, so distant that man's life is all too short for the journey. There are various sorts of success, but there is only one which will win you the applause of our great profession—to leave it better, by your own efforts, than you entered it. The temple of medicine has been reared by innumerable workers, and of it certain great ones have erected whole halls and lofty spires by themselves. Emulate them if you can, but if it can be recorded that you built but one sound stone into the structure you will not be without everlasting honour.

And, finally, let me whisper in your ear that the policy of buying to-morrow with to-day is economically unsound, and remind you of the words of a poet who himself attained to immortality:—

> "Oh, talk not to me of a name great in story,
> The days of our youth are the days of our glory,
> And the Myrtle and Ivy of sweet two-and-twenty,
> Are worth all your laurels, though ever so plenty."

THE PROFESSION OF MEDICINE.

Being part of an Address to Students of the Westminster Hospital on Oct. 3rd

BY E. W. AINLEY WALKER, D.M., D.SC.,
DEAN OF THE SCHOOL OF MEDICINE, UNIVERSITY OF OXFORD.

I THINK it is no empty boast to claim that here in England the leaders of the profession have long been pre-eminent in the art of medicine; but it was not until comparatively lately that the application of pure science, and even of the biological sciences, to medicine received the recognition it deserved. In this respect there has been an enormous change in quite recent years, and it is now generally agreed that accurate scientific knowledge is the only valid basis for lasting success in the application of our art.

Whereas every day's experience in the practice of medicine must necessarily entail an unconscious steady growth, in skill, in clinical insight, and in power of management of the individual patient, an adequate knowledge of the fundamental sciences upon which all progress depends can only readily be acquired by close attention during the brief student period. The man who does not during this time obtain a thorough knowledge of the principles of the fundamental sciences, and some working acquaintance with the ascertained facts, will find himself, after 10 or 20 years of practice, so completely out of touch with the advance of science as to be quite at sea in the application of new facts and new methods. On the other hand, the student who trains himself thoroughly in scientific method has placed himself in a position to assimilate every new advance and to apply it to the benefit of his patient. For my own part I look forward to the time when every student will require himself to take a degree in pure science as a part of his medical studies.

I am becoming uneasy lest amid the multiplicity of subjects with which the student is now required to acquaint himself he may not get that sound knowledge of general medicine and surgery which remains fundamental to the education of the doctor. If we are to avoid disaster it must always be remembered that education is primarily a training of the mind. It is intended to fit the mind to apply itself to each problem that arises, whether that problem has been met before or presents novelty. It is not intended to convert the student at the moment of graduation into a walking encyclopædia of medicine, but rather to give him facility in the use of those faculties of observation and reasoning, and those methods of investigation which will enable him from the first to deal with the ordinary run of practice, to be competent in its common emergencies, not to make gross mistakes and to know when he needs to seek assistance. Hence it is of the first importance that we should not mistake a smattering of information on an infinitude of little special subjects for an education that will fit men to become competent physicians.

It is on the scientific side of medical training that the greatest blots remain. I refer to the comparative neglect of the foundation of medicine—pathology—and the still graver neglect of the foundation of therapeutics—experimental pharmacology. In regard to pathology, there has been an awakening and the neglect is gradually being remedied, though the subject does not yet take that important place in the course of the ordinary medical student to which it is entitled. But the neglect of pharmacology is unfortunately almost unheeded, although on its experimental side the subject offers almost unlimited possibilities to-day. The enormous strides which have been made in our knowledge of organic and synthetic chemistry, and in our acquaintance with hormones, with internal secretions, with vitamins, and with other products of the activities of living matter have opened a wide field for experimental and therapeutic investigation—a field which, because it has been neglected by the faculty, has rapidly become commercialised in certain countries with results that are, as I think, highly detrimental to real progress in the treatment of disease. It is hardly too much to say that a new kind of quackery has sprung up, which is all the more dangerous because it is the doctor rather than the public who is the intended guy upon whom vaunted but ill-tried remedies are daily being pressed in those futile piles of puffs and specious advertisements that fill his morning's post and crown his breakfast table. On this account, if on no other it is high time that due attention be given to the teaching of pharmacology.

Lastly, there is a pressing need for the fuller development of post-graduate study and the organisation of clinical research. After a period of practical experience many a man would welcome the chance of some post-graduate work as an opportunity of filling up the gaps, or of making further advance in some special branch, and I feel sure that if adequate post-graduate facilities were generally available in the schools, the great majority of medical men would sooner or later gratefully avail themselves of the opportunity of returning from time to time for the refreshment of their knowledge, the adjustment of their outlook and the awakening of that renewed activity of mind that we call keenness, which results from contact with the work and spirit of a teaching hospital. The establishment of post-graduate teaching would infallibly lead to renewed activity in the field of clinical research, a department of medicine in which at the present time we seem to be making somewhat less progress, in comparison with other countries, than we have a right to expect. There is the less excuse for this state of affairs in that by far the majority of men of outstanding ability in medicine in this country turn into clinical work. The explanation no doubt lies partly in the peculiar difficulties which beset clinical investigation, but to my mind it lies quite as much in the absence of that stimulus which in other departments of medical science is afforded by the presence in their laboratories of post-graduate pupils and research workers.

Clinical research is, almost necessarily, a more severe and arduous discipline than the general run of pure laboratory investigation. The laboratory worker is fortunate in that he is able to select his problem

He can arrange its conditions, he can vary them at will, and he can repeat his experiment as often as he chooses, ringing the changes in this direction and in that until he is able to evaluate precisely the bearing of each factor and the meaning of the whole phenomenon under examination. The clinician, on the other hand, has to take his problem as he finds it, the conditions are set by nature, and she takes pleasure in subjecting them to all kinds of arbitrary variation; perhaps few, if any, of the factors may be under the control of the observer, and even the problem itself is often difficult to isolate and to define precisely. Yet every page in the history of medicine proves that all such difficulties can be overcome.

DENTAL RESEARCH AND ITS SERVICE TO THE NATION.

Abridged from an Address delivered at the Opening of the J. H. Hale Laboratory, Royal Dental Hospital, on Oct. 4th

BY SIR WALTER FLETCHER, K.B.E., M.D., F.R.S.,
SECRETARY OF THE MEDICAL RESEARCH COUNCIL.

AFTER congratulating the school on a successful year, and welcoming the new students, Sir Walter Fletcher continued :—

The special event of to-day is the first opening of the new research laboratories which have been built here by aid of a grant from the United Kingdom Dental Board. Their equipment and upkeep have been provided in chief part by the generosity of Mrs. Hale, who dedicates her gift to the memory of her husband, John Hampton Hale, formerly chairman of the hospital. These new laboratories are undoubtedly a valuable addition to the school, but the significance of our ceremony to-day goes far beyond that. The laboratories are an outward and visible expression, perhaps the first which the public have had an opportunity of noting, of a new and very striking movement in the dental profession. I doubt the general public having any conception of the new policy by which the dental profession are themselves directly supporting and promoting both education and research in their art and science. Under the United Kingdom Dental Board, every practitioner registered since 1921 pays not only a registration fee but also an annual fee, and as the register grows, the whole dental profession will be included as contributors. The fund already amounts to about £40,000 a year, and this is spent under the management by the Board in promoting education and research, and the public ought to notice and appreciate this most honourable and enlightened policy, at present almost unique in its kind. Dental practitioners are directly and with good will supporting a fund for promoting the two great movements that in a narrow view might seem to be most damaging to their immediate self-interest —education, bringing into the competitive field the ablest and best-equipped rivals, and research, of which the deliberate aim is to prevent dental surgeons so far as possible from having any work to do at all. Could there be a more notable example of public-spirited altruism? Now that the lead has been given by the dental profession, we may all wish that admiration by other professions of their movement may presently stimulate imitation. Supposing members of the medical profession each paid a small annual contribution in recognition of the privileges given them by registration, and that the fund so produced was devoted in the high spirit of altruism to the interests of the public by being used to promote improved and better sustained medical education, and in gaining improved medical knowledge through research! Do you realise that if each doctor in the United Kingdom contributed what each dentist now contributes, there would be a fund of no less than a quarter of a million sterling annually for medical education, whether undergraduate or post-graduate, and for medical research?

In framing their research policy the Dental Board have entered into coöperation with the Department of Scientific and Industrial Research, and for study of their special problems in mechanics, metallurgy, and refractory materials, have thus taken into alliance the whole system of scientific effort throughout the country with which that Department is in touch.

A coöperative alliance has also been effected between the Dental Board and the Medical Research Council in respect of research in dentistry upon the preventive and curative side. There are few problems of preventive medicine of more significance to the race, and not least to the people of our nation at present, than that of the proper development and preservation of the teeth. Every modern gain in our knowledge only serves to emphasise in some new way the scientific and medical interest of this set of problems. The Council I serve have recognised this from their beginning, and so far as their means allowed have lost no opportunity of assisting work in what is in many respects a peculiarly difficult field. They greatly welcomed the coöperation which the Dental Board offered them four years ago, and now the two bodies join together in financing the schemes of research recommended and generally supervised by an investigation committee upon which laboratory workers in bacteriology, biochemistry, and nutritional physiology sit side by side with clinical and anatomical observers under the chairmanship of that distinguished member of your staff here, Mr. Norman Bennett. My Council belief, and they hope the Dental Board also are satisfied, that by this partnership economy is well served and scientific efficiency increased. It will be our hope that the new laboratories we are to inaugurate to-day will play their own distinguished part in this coöperative scheme of investigation.

Who can doubt the value of this research work? It is now almost a commonplace to say that the improvement of the teeth of the nation is one of the most urgent of outstanding problems in prevention. Yet while we recognise this, it is useless and perhaps worse than useless to demand or expect quick and easy results from the investigations. Money is necessary to get freedom and opportunity for the right workers, and money invested in research rarely fails in the long run to give a high return of interest and often at an almost fabulous rate. But you cannot by merely putting money down either secure quick results or, indeed, command any at all. New natural knowledge cannot be bought; it is the product of the right man in the right place and of his unfettered labour. As Bishop Hall, of Norwich, said truly 300 years ago: "There was never good thing easily come by . . . God sells Knowledge for Sweat." Further, the endowment of research not uncommonly leads to a research after endowment. There are always those, whether trained or untrained, who are ready to undertake investigation in any direction without definite clue or clear objective. The true limit to a research programme is fixed not by the money at disposal but by the number of persons fit and available, and they will always be scarce. We must not only be patient in waiting for results but catholic in our scientific spirit. With a definite utilitarian goal before us, as here, that of preventing dental disorders, there is a common danger of expecting success from the frontal attack and of neglecting to observe and foster the progress of those who, perhaps in some quite different field of work, are reaching a point from which a flank attack may gain the whole position we are seeking. Nature's clues rarely lie in the straight line and the key to some great advance in dental knowledge may be lying implicit in studies that seem now to be quite alien. To those who can help us by some other road upon the flank we must be more encouraging than the Irishman who, when asked by a belated traveller the way to Roscommon, said: "Bedad, and it's a long way. If you're going to Roscommon you shouldn't be starting from here."

What has been needed, and what the committee have been giving their chief energies to obtaining, has been better knowledge not so much of dental

disease as of dental health; not so much of the specific diseases that may attack the teeth as of the conditions upon which their natural resistance to disease depends. Recent work in this country has drawn increasing attention to the exquisite elaboration of the minute architecture of the teeth, not only as it is built up when the tooth is first constructed for its long years of hard service, but also in the processes of its repair against later damage. Evidence has been accumulating that if this architecture be perfect, as it should normally be, the attacks of disease are prevented or minimised.

Recent work has been increasingly bringing dental problems into line with those of general physiology. The normal architecture of the teeth, like that of the bones and other organs of the body, depends upon the right supply and balance of particular parts of the diet during their growth. It seems that whether from the very intricacy of their wonderful structure or whether for other reasons the teeth in their formation are even more sensitive to nutritional conditions of given kinds than other parts of the body. Certainly we all know how often a human body, splendidly formed and functionally fit in every other way, is marred only by faulty teeth. Dental practitioners in the future may have new and wider service to give by aiding their colleagues in other medical fields to use the new and sensitive index to complete normality which the teeth in their formation and repair seem destined to provide. The progress made in these directions is full of hope because we seem to be in sight of new powers altogether, in the light of this new knowledge, and full of interest because at every step in the work problems of deep significance in biological science are being raised and illuminated. It has special interest, too, because the advances made here are all tending to bring preventive dentistry into new and closer relations to the general body of medical science. Solomon said in his wisdom: "Hardly do we guess aright at things that are upon earth and with labour do we find the things that are before us." Here and to-day in your new laboratory we dedicate a fresh enterprise in the long quest for knowledge; we shall pray that it may serve well the highest interests of your profession and bear its due part in winning more knowledge for the dignity and interest of mankind and more power for his help in this and other nations.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments have been made: Surg-Comdrs. R. J.G. Parnell to *Queen Elizabeth* and to *Warspite*, as squadron medical officer and for specialist duties on station (on transfer); W. N. L. Cherry to *Queen Elizabeth*, as Fleet M.O. (on transfer); and C. H. M. Gimlette to *Effingham*, as specialist in ophthalmology (on recommg.). Surg. Lt.-Comdr. A. W. North to *Titania* (on relief). Surg. Lts. P. J. A. the O'Rourke to *President*, for course of instruction, and to *Dolphin*; and A. E. Phillips to *Ambrose*.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg.-Lt. R. A. Connon to be Surg.-Lt.

ROYAL ARMY MEDICAL CORPS.

Maj. F. R. S. Shaw (secd.) retires, receiving a gratuity.

Temp. Capt. W. L. Hay relinquishes his commn., and is granted the rank of Maj.

Lts. (on prob.) confirmed in their rank: W. G. S. Foster and W. F. Cooper.

ROYAL AIR FORCE.

Flight Lt. P. D. Barling is granted a permanent commission in this rank.

VOLUNTARY AID DETACHMENTS.

Substantial progress continues to be made in the organisation of Voluntary Aid Detachments, as part of the voluntary reserve of the Medical Services by the Crown, under the scheme which was launched four years ago with the approval of the Army Council. Detachments numbering 821 have now received official recognition, and their members number 20,077. Of these 3180 have undertaken an obligation to serve at home or abroad in the event of a national emergency, while the others have agreed to do duty as they may be required within reach of their homes.

Special Articles.

REQUIREMENTS OF THE POPULATION IN MILK-FAT AND THE AVAILABLE SUPPLY.*

BY W. CRAMER, D.SC. EDIN., PH.D. BERLIN, M.R.C.S. ENG.,
RESEARCH ASSISTANT, IMPERIAL CANCER RESEARCH FUND.

THE work of McCarrison and the experiments which I have carried out with Drew, Kingsbury, and Mottram have shown that a diet may contain a sufficient amount of vitamins to prevent the occurrence of the so-called deficiency diseases, but may, nevertheless, be so poor in its vitamin content as to prevent an animal from maintaining its health. A study of the mode of action of the vitamins has led us to conclude that these substances have a specific stimulating action on certain tissues and organs in the body of the living animal. If this stimulus is not supplied in the food in adequate amounts the functional activity of these cells or tissues is impaired. The degree of impairment varies with the degree of inadequacy in the supply of the stimulus and with the length of time over which it is allowed to act. In this manner all degrees of deviations from health are produced by diets inadequate in their vitamin content. The mode of action of vitamins resembles in many respects that of hormones, and the term "food hormones" enables one to form a mental conception of the manner in which disturbances of health can result from diets showing varying degrees of inadequacy in their vitamin content.

In order to study these conditions it is necessary to work over long periods and on a population of animals bred in the laboratory from a known stock and kept under controlled conditions. It is thus possible to show that rats kept on a natural diet poor in vitamins, such as white bread, maize, and rice, will grow and breed and present an apparently normal appearance. But when compared with another population in which an ample supply of vitamins has been added to this diet, it will be found that on the poor diet they do not grow as well as on the rich diet, nor are they able to rear their young as well. Perhaps the most striking difference is that on the poor diet the older animals develop almost without exception an infection of the lung (septic broncho-pneumonia), while on the rich diet this is a rare occurrence. Mellanby has recently confirmed this observation in experiments on dogs. As I have shown in previous publications, the literature contains ample evidence that similar conditions obtain in the human subject. In industrial schools apparent epidemics of pneumonia have occurred and recurred, before we knew of the existence of vitamins, in spite of the greatest attention given to housing. A revision of the diet in the light of our present knowledge of dietetics showed that in these schools the diet contained an inadequate supply of vitamin A, and when this error was corrected these apparent epidemics ceased. It is not unreasonable to suggest that the frequency with which broncho-pneumonia occurs in the children of the poorer classes is due to this dietetic error.

A study of the mode of action of vitamin A has afforded an explanation of this remarkable fact. Vitamin A has a specific stimulating action on the mucous membranes, especially those of the respiratory and digestive tracts. These are always in contact with bacteria, but in perfect health the bacteria are not enabled to infect these mucous membranes because the secretion of mucus acts as a mechanical and possibly also a chemical defence against the

* A paper read before the Section of Physiology at the meeting of the British Association in Leeds.

bacteria. If the supply of vitamin A is inadequate the activity of the mucous secreting cells is impaired; they become atrophic, and then the bacteria are enabled to penetrate into the mucous membranes, and produce varying degrees of infection of these tissues. These infections may remain localised for a long time in the affected mucous membranes or lungs and produce apart from the local disease a general toxæmia. If sufficiently prolonged bacteria pass into the blood stream, exhaust the humoral defensive mechanism, and set up an infection elsewhere or even a mild septicæmia. These effects are accompanied by changes in the blood, a thrombopenia and an anæmia. The importance of these findings lies in the fact that the mucous membranes of the respiratory and digestive tracts are the portals through which most bacterial infections to which we are prone enter. It is, therefore, in our power to increase by dietetic measures our resistance to such infections. These findings have been confirmed and extended recently by Koessler, Maurer, and McLoughlin,[1] who have also successfully applied these experimental results to the treatment of anæmias in man.

Another striking demonstration of the truth of these statements and of its applicability to man has been furnished recently by the important investigation of Dr. Corry Mann [2] on boys in an institutional school carried out under the auspices of the Medical Research Council and published by them. I cannot do better than quote from the official introduction to this report:—

"It is difficult to exaggerate the social value and the national importance of knowledge which may help to solve the problem of what diet in quantity and in quality provides adequate nutrition for the growing boy or girl. Adequate nutrition we take here to mean that which allows the full unfolding in growth of the best potential qualities, physical and mental, inherent in the child at birth. . . . The need for criteria of 'adequacy' in a dietary is felt most, of course, when circumstances demand economy in the choice of its constituents. It is a need, appreciated or not, for all classes of the community in different degrees. Unless the defects in nutrition which follow upon the use of a given diet are of an obvious kind, unjustifiable faith in the adequacy of a diet may easily arise. The supply of a dietary tends to become traditional and its efficiency unquestioned. Appetites may be apparently satisfied, and if the health and progress of individuals fail to reach a high standard the explanation is commonly sought in the factors of past history and inheritance as affecting children, derived for the most part from the lower social strata. Only close and discriminating study can decide between the influence of such factors and that of possible dietetic errors.

"The investigation shows clearly that the nutritive value of a dietary, which was originally chosen with every regard for the welfare of the children to be reared upon it, could be strikingly improved by additions which, in a quantitative sense, were small. It is startling to learn, as we do now, for instance, that the addition of one pint of milk a day to a diet which by itself satisfied the appetite of growing boys fed upon it, could convert an average annual gain of weight of 3·85 lb. per boy into one of 6·98 lb., and an annual average increase of height from 1·84 inches to 2·63 inches. This unmistakable betterment in nutrition was proved by trial to be due, not to the relatively small increase in the fuel value of the dietary, nor to the extra protein supplied in the milk, but rather to more specific qualities of milk as food. . . .

"It is of the first importance to notice that the improved gain in weight and height, taken as the measurable characters in this inquiry, were found to be accompanied regularly by improved general health and 'spirit.' If the nervous system of a growing boy is improved in its nutrition and one, it does not follow that under ordinary conditions he will show better mental proficiency in school marks or better conventional behaviour. As Dr. Corry Mann observes, the boys who got the extra ration of milk and did best in weight and height were easily recognisable as 'obviously more fit than those of the other groups.' This was the testimony of all those who saw the progress of the inquiry. The improved 'spirit' of these boys led to their being more often in trouble for minor offences against order. No measurable indications were found of their having greater proficiency at school work, but this, in the absence of any modification of disciplinary or teaching methods, is not to be weighed against the general evidence for greater mental vigour. Common sense will always hold that high spirits are a sign of healthy boyhood, and that no dietary can be 'adequate' that does not permit their full development."

Another significant effect of the addition of milk is given in the following statement taken from Dr. Mann's report (p. 33):—

"During the winter of 1923–24 there was a complete absence of illness among the boys with the milk ration, although in other houses of the village the sickness-rate had been somewhat higher than usual owing to naso-respiratory catarrh (influenza), and to a limited outbreak of measles and scarlatina."

The observations made by Dr. Corry Mann on growing boys are thus an almost complete replica of our observation on animals, in which a similar result was obtained by adding substances rich in vitamin A and B to a basic diet otherwise poor in these vitamins. Although Dr. Corry Mann does not definitely state that he attributes the effects observed to the presence of vitamins in the milk or in the butter, which in another group was added to the diet with similar good results, an examination of his basic diet shows that it was poor in vitamin A and certainly not abundant in vitamin B. The main supply of vitamin A in the basic diet was represented by about 3–4 oz. of milk per head per day. In this connexion it may be stated, although it is obvious, that the vitamin A content of milk is not the only factor which confers upon milk its high dietetic value. Other factors are the high mineral content of milk which is of special importance to the growing organism and the presence of a protein (caseinogen) of high biological value.

As stated in the introduction to Dr. Corry Mann's report, height and weight are the only measurable criteria of dietetic efficiency. They are also the most obvious ones, and it is for this reason that the dietetic errors with which we are dealing here are most readily observed in children. But in so far as liability to infections of the mucous membranes and mental vigour are dependent upon dietetic factors, the adult organism is as much dependent upon an adequate diet as the growing one, and it would be a serious error to neglect the importance of an adequate vitamin supply for the adult organism.

In our experimental observations we have brought abundant evidence in support of the contention that an ample supply of vitamins is as essential for the adult organism as it is for the growing organism. We also wish to emphasise the importance of Dr. Corry Mann's observations upon the psychological effects of a diet inadequate in specific substances.

It is clear then that the living organism cannot attain its full development or maintain it without a supply of vitamin A very much larger than that necessary to prevent the specific deficiency disease or even any obvious forms of ill-health. Taking into consideration the dietetic habits of the population in this country, the problem of providing an ample supply of vitamin A in the diet resolves itself from the practical point of view into the problem of providing an ample supply of milk or butter. It is therefore a question of considerable importance to ascertain the minimum of milk-fat which ought to be included in our dietary and which may be taken as a measure of the requirements of man in vitamin A. The evidence bearing on this point is essentially circumstantial. One indication is given by the amount of milk consumed by an infant when it is weaned. This is 1 quart per day and contains about 40 g. of milk-fat. In an extensive investigation into the food requirements of children, Holt and Fales[3] come to the conclusion that the requirements in fat as such (not necessarily milk-fat) increase proportionately to the weight so that for every age the fat requirement is about 3 g. per kilo body-weight. Thus from the 36 g. of fat consumption of the first year the requirement gradually increases to 100 g. at about 10 years of age and rises even higher to 125–150 g.

[1] Jour. Amer. Med. Assoc., 1926, lxxxvii., 476; 1927, lxxxix., 38.

[2] Report of Medical Research Council, 1926. Special Report Series No. 105.

[3] Amer. Jour. Dis. of Children, 1922, xxiii., 471.

from 13–16 years. In the first year the fat requirement is covered entirely by milk-fat taken in the form of milk. As the child grows older the fat requirement is covered partly by butter, and later also by animal fat and the milk consumption diminishes proportionately. It can hardly be doubted that where there is a free choice of diet the bulk of the fat requirement would be covered by the consumption of milk, cream, and butter. It has been stated already that the special value of milk to the growing organism lies not only in its vitamin A content, but also in its content of mineral salts, of which the growing organism is particularly in need.

In the dietary recently drawn up for a New York hospital for children [4] 1 quart of milk per day and 1½ oz. of butter are given as the daily allowance. This would represent a consumption of milk-fat of about 80 g. In a study of the dietary of an American public school Gephart [5] gives a daily consumption of fat of 200 g. per day per boy, which was covered almost entirely by milk and butter. Gephart describes the diet as ideal, and states that the place held by milk in this dietary is to be commended.

A measure of the amount of milk-fat required by an adult person may be obtained by determining the amount of milk-fat consumed by normal adults where there is a free supply of milk and butter, so that the consumption is not limited by economic considerations, but is conditioned merely by the normal appetite. From observations in a household where butter appears on the table at every meal, I find that the average consumption of an adult person is 1 oz. of butter and ½ pint of milk per day. On looking up an old text-book of physiology,[6] written before the discovery of vitamins, I find in the dietary given as a specimen 1 oz. of butter and ¾ pint of milk per day. These figures again represent 40–50 g. of milk-fat per day. Widmark [7] gives 52 g. of milk-fat per day as the average daily consumption of milk-fat among the working classes in Sweden. In an interesting paper Widmark shows how, as the result of the Great War, a whole nation—Denmark—has been made the involuntary subject of an experiment demonstrating that the health of a population improves when the average consumption of milk-fat is kept above a certain level. This level Widmark finds to be 40 to 50 g. of milk-fat.

It is significant that all the evidence bearing on the requirement of milk-fat in the diet leads to a minimal figure of 40 to 50 g. per head per day, or in ordinary terms, a glass of full milk and an ounce of butter. If this figure is accepted as a basis, it is possible to calculate the requirements of milk-fat per annum for the population of this country. The milk-fat available for consumption can be calculated from the milk production in this country and from the import of butter. The amount of condensed milk imported has not been brought into the calculation, partly because its vitamin A content is often poor and also because in any case the amount of condensed milk imported is relatively so small that it does not seriously affect the conclusions which can be drawn.

The calculation is as follows :—

Requirements.

a Consumption of milk-fat per person per day, 40–50 g. Total requirements of population (43 millions) per annum =628 to 785 million kg.

Available Supply.

b Home milk production=1350 million gallons=6142 million litres=6327 million kg. milk=253 million kg. milk-fat.

c Imported butter=268 million kg. Imported milk-fat =227 million kg.

b & *c* Total milk-fat available=480 million kg. Available, if rationed, 30 g. per person per day.

a—(*b* & *c*) Deficit of available milk-fat=148–305 million kg.

[4] Carr, W. L.: Bull. New York Acad. of Med., 1927, iii., 453.
[5] Boston Med. and Surg. Jour., 1917, clxxvi., 17.
[6] Stewart, G. N.: Manual of Physiology, fourth edition, London, 1900.
[7] THE LANCET, 1924, i., 1206.

The calculation shows that there is a considerable deficit of available milk-fat. Some idea of its extent can be gathered from the fact that the milk-fat available, if rationed equally, would give only 30 g. per head of the population. Since a large part of the population consumes its ideal minimal quota of 40–50 g., and a smaller part will even exceed it, it is clear that another large part of the population will have a consumption of only 20 g. of milk-fat and even less. Since this paper was read the annual report for 1926 of the Chief Medical Officer of the Ministry of Health has been published in which reference is made to the same problem. Sir George Newman states (p. 185) :—

"The average daily milk consumption of the population of England and Wales has been estimated at about one quarter pint per head, and in some populous districts is as low as 0·08 or even 0·06 of a pint per head."

Another point which should be noted is that only one-half of the available milk-fat is produced at home, the other half of the available milk-fat is imported from abroad. The countries mainly responsible for this supply are Australia and New Zealand which supply one-third of the imported butter, and Denmark which supplies another third. I have no information whether the average milk-fat consumption in Australia reaches the ideal minimal ratio of 40–50 g. per day per head, so that the exported butter would represent a surplus. For New Zealand I am indebted to the High Commissioner for New Zealand for supplying me with the following figures for the year 1924–25 :—

Article.	Production.	Excess of exports over imports.	Amount available for home consumption.	
			Quantity.	Per head
	lb.	lb.	lb.	lb.
Butter.. ..	181,657,666	140,549,771	41,107,895	30·3
Dried milk..	14,459,370	10,854,525	3,604,845	2·6
Preserved milk.. ..	5,261,648	1,666,382	3,595,266	2·6

The average daily consumption of butter in New Zealand per head amounts therefore to over 37 g., 32 g. of milk-fat. This figure is actually higher than that postulated by us as the minimal optimum requirement of milk-fat consumed in the form of butter. Although the consumption of milk as such cannot be calculated from these figures they are sufficient evidence to show that the people of New Zealand are covering their minimal requirements in milk-fat before exporting any of it, so that their exports represent a surplus. The figures also show that we have not over-estimated the amount of milk-fat consumed as butter where it is freely available. But as far as Denmark is concerned, the export of milk-fat does not represent a surplus, so that the Danish people are starving themselves of milk-fat in order to export it. Widmark in his paper shows that the average daily consumption of milk-fat in Denmark has fallen from 40 g. in 1909 to 30 g. per head in 1919, with a demonstrable deterioration in the health of the people. During the years 1917 and 1918 the export of milk-fat was forbidden, and although less milk-fat was produced during those years the average consumption of milk-fat fell again rapidly to the low figure of 19 g. per day per head in 1920. As the consumption of butter diminished, that of margarine has increased proportionately. It will be noted that the low figure of the milk-fat consumption in Denmark for 1914 closely approximates that found for the country, in spite of the fact that in Denmark the home production of milk-fat exceeds the needs of the population. Economists will probably tell us that this must necessarily be so because milk-fat, like any other commodity, is subject to economic laws. But the economy of foodstuffs cannot be divorced in

ong run from dietetics. The replacement of butter y margarine may appear to be justified on economic rounds, because the cost of butter is twice that of nargarine. On dietetic grounds, however, butter is ot merely twice as valuable as margarine, but is in act irreplaceable by it, so long as the minimum equirements of milk-fat have not been covered. hat is to say, margarine can replace butter after the inimum daily requirements of 40 to 50 g. of milk- t have been supplied. But until this amount has een supplied it is more economical to buy 1 oz. of utter than to buy 2 oz. of margarine, which cost ne same amount. Even from the point of economics ne cost of imperfect development, ill-health, and sease ought to be debited against a dietary which not adequate. Once this is recognised there will e an enormous demand for milk-fat which, as things re at present, cannot be supplied.

It would be important to know the production of ilk-fat and the consumption in the different civilised ountries. It would also be of importance to ascertain hether during the last 20 years the production of ilk-fat has kept pace with the increase in the popu- tion. I believe it will be found that at present e are suffering from a world shortage in the production milk and, if the conditions in Denmark may be ken as a guide, that this shortage has been becoming creasingly acute during the last 20 years. A easure of the present shortage is given by the nsumption of margarine in different countries. his can be seen from the following figures which ve the yearly consumption per head in English ounds :—

Denmark	45·50	Sweden	12·25
Norway	35·25	England	11·75
Holland	15·70	France	1·50
Germany	12·30		

the daily consumption of margarine per head is lculated for England it amounts to 14 g. The erage daily consumption of milk-fat (30 g.), plus argarine (14 g.), is therefore 44 g. Since this rees with the figure of 40–50 g. given by us as the nimal daily requirement in milk-fat, it confirms r contention that on a freely chosen diet this nount of milk-fat would be consumed, and attests e soundness of the basis of our calculation for the quirements in milk-fat of the population.

It has been argued that the shortage in milk pro- ction is not of serious import, because other sources vitamin A are available in nature. This objection trays a complete misunderstanding of the problem. goes without saying that there is sufficient vitamin A ailable in nature to cover our requirements. For far as we know the cow does not synthetise the amin A which is passed out in the milk, but derives from the food. All the dairying in the world nnot, therefore, increase the store of vitamin A ailable in nature. What dairying does is to present amin A in articles of food which are palatable, nvenient to handle and to consume, and valuable food also from other points of view—for instance, a source of a protein of high biological value, and those mineral constituents in which most other odstuffs are deficient. Whether for reasons such these or on other grounds, it is a fact that for the ople of this country the main source of supply of amin A in the diet is full milk and butter. More- er, their dietetic habits are such that where full lk is not consumed and butter substituted by rgarine, the resultant deficiency in the intake of amin A is not compensated for by an increased ake of other articles of food containing vitamin A, h as green vegetables or salads, although in ory they would be able to do so. Here, again, nomic considerations probably play an important t.

We have to deal with conditions as they are and as they might be. We have shown that large sses of the community suffer from a deficient ake of vitamin A. The remedy of this defect is a ficult and intricate problem. It is intricate because it involves the consideration of economic factors, of taste, of dietetic habits, and of a better understanding of the dietetic value of articles of food. One obvious remedy is the increased production of milk which is irreplaceable as such, and of special value to the growing organism. I believe it is not an exaggeration to say that a flourishing dairying industry, capable of supplying clean milk rich in vitamin A, is essential to the welfare of the community. The shortage in the production of milk is, however, so great as to make it improbable that it could be overtaken even if the milk production is greatly increased. There are also economic reasons which will make it impossible for large classes of the community to cover their vitamin A requirements completely by milk-fat. The necessity of a cheaper substitute for milk-fat will therefore remain, but it is desirable that this substitute should approximate more closely to the dietetic value of milk-fat than it does at present. The deficiency of margarine in vitamin A, and also the deficiency in calcium salts, in which butter is relatively rich, make margarine an inadequate substitute for butter. This defect can be remedied, for I am informed that a brand of margarine as rich in vitamin A as butter is already available on the market. It is significant, however, that its price is higher than that of the best margarine, though still lower than that of the cheapest butter.

The solution of these problems is dependent upon the collaboration of the medical profession. While it is obviously impossible to increase the consumption of milk and butter without increasing their production, it is also unreasonable to expect the farmer to increase the production of milk unless he can rely on an increased demand for milk and butter by the population. This can only be created by the teaching of the medical profession, upon which in matters of dietetics the public relies. On the other hand, the medical profession can impress upon the farmer the necessity of producing milk which is clean and rich in vitamin A. Fortunately, a beginning in this direction has already been made. No less an authority than Sir George Newman states in his report already referred to—"On the State of the Public Health" (p. 186) :—

> "When it is realised that little more than a quarter of a pint is the average daily consumption of milk in this country at the present time, some conception can be formed of (*a*) the inadequacy of the amount of this most valuable food, which its children are receiving, and (*b*) the improvement in their growth and vigour which might certainly be secured by an adequate increase in its consumption. . . . An important factor in bringing about this much desired result is the creation of confidence in the purity of the supply, and making milk more attractive to the consumer by enhancing its cleanliness and its keeping qualities."

For reasons already given in this paper, these considerations should apply also to adults and to their consumption of butter.

Summary.

1. It is possible to calculate the vitamin A requirements of man in terms of milk-fat. Every individual requires an average daily consumption of 40 to 50 g. of milk-fat, either in the form of milk or butter, in order to maintain his full health and vigour. This applies both to adults and to children. At the present time the average daily consumption of milk-fat is far below that figure for a great part of the population.

2. The total milk-fat produced in this country represents only 30–40 per cent. of the total average requirements of the population. The total milk-fat available in this country (home-produced milk-fat plus imported milk-fat) represents only 60–75 per cent. of the total average requirements of the population.

3. There are indications of a world shortage in the production of milk.

4. These conclusions emphasise the importance of increasing the production and the consumption of milk and butter.

ST. MARY'S POST-GRADUATE COURSE.

FOR the sixth consecutive year a refresher course, open without fee to all medical practitioners, was held at St. Mary's Hospital, London, over the first week-end in October and was well attended. While the majority of the 11 sessions were in the nature of informal demonstrations it is possible to epitomise several of the lectures.

The Treatment of Pernicious Anæmia.

Sir WILLIAM WILLCOX said that early recognition of the disease is a most important factor in the treatment of pernicious anæmia. A definite anæmia associated with a colour-index of approximately 1 or over, with a leucopenia, and a differential count showing diminution of the polynuclear leucocytes, and an increase in the lymphocytes, should be a sufficient indication of the pernicious type of the anæmia. Careful investigation and active treatment in the early stages may be rewarded by arrest of the disease and, he believed, by complete cure in some cases. In undertaking the treatment of a case it must be borne in mind that the disease is progressive, and will inevitably proceed to a fatal termination if left unchecked; therefore no effort should be spared to eliminate any possible causal factors, and the fullest advantage must be given to the beneficial value of a special diet, rest, general hygienic conditions, and medical remedies.

The first step in treatment is careful investigation for any possible causes which may be contributing to the blood destruction. All authorities are agreed that septic infection in the body is an important causal factor. In the many cases which had been under his care, and in which careful investigations had been made, there had always been definite evidence of toxic causes which he thought was amply sufficient to account for the symptoms of the disease. In pernicious anæmia the blood-forming organs appear to bear the brunt of the underlying toxæmia present. The teeth should be examined clinically and radiographically, and all those showing evidence of sepsis, and also loose or dead teeth, should be removed. The accessory nasal sinuses should be examined clinically and by X rays, and suitable treatment given to minimise infection from these sources. Septic tonsils should be removed. The gastro-intestinal tract should be investigated by X rays, by test-meal, and bacteriologically. The urine should be tested for indican for evidence of colon stasis. In most cases of pernicious anæmia a secondary infection is found in the intestinal tract (probably mainly in the colon), and this serves to maintain the infection when other causes have been removed. Suitable treatment for any abnormal condition should be carried out. Often Plombières colon irrigations on alternate days are of value. The urogenital tract should be investigated clinically and bacteriologically, and, if necessary, any abnormal conditions treated. The organism most commonly found present is a streptococcus, which may be of the viridans or hæmolytic type. Sometimes a coliform organism of hæmolytic type may be found. Vaccine therapy may be of value in aiding the removal of infective causes. Great care is necessary in its use, since these patients are usually sensitised to the underlying infection, and weak vaccines in small doses are indicated.

The careful and able investigations of Murphy, Minot, and their colleagues in America into the value of a special dietary in pernicious anæmia form a marked advance in the treatment of this disease, continued Sir William Willcox. They have shown that a diet composed of foods rich in complete proteins —particularly liver—and containing an abundance of muscle meat, fruit, and green vegetables, and low in fat, is of great advantage. They recommend as daily requirements: liver or kidneys, 20 g.; red muscle meat or heart, upwards of 125 g.; green vegetables, not less than 300 g.; fruits (grape-fruit, oranges, &c.), 400 g.; fats restricted to 70 g.; bacon, cheese, and fried foods to be avoided; milk to be limited to 240 g.; starchy foods not to be taken in excess. A very careful investigation of 46 cases has shown marked improvement after two weeks' treatment by the above dietetic régime. And the improvement has been maintained while the patients have followed the recommendations. Before commencing the special dietetic treatment, it is necessary to carefully study the digestive capacities of the individual so that the diet treatment may be undergone without distaste. From trial of the suggested diet in several cases under his care, Sir William Willcox was convinced that it is of value and marks a distinct advance in treatment.

Hydrochloric acid is of definite value. It should be given in doses of ℥ xx.–xxx. of the dilute acid (B.P.), diluted with 3 or 4 oz. of flavoured water and sipped with the meals. Murphy recommends the use of hydrochloric acid with his special diet. Arsenic has been one of the most used remedies. It may be given in the form of liquor arsenicalis or the hydrochloride solution. It should not be given in too large doses, owing to the risk of symptoms of arsenical poisoning, such as neuritis. Arsenophenol compounds intravenously have been recommended but in the speaker's experience they are not usually of value, and may be dangerous, since hepatitis and jaundice may result from their use. Arsenite of iron in solution may be given intramuscularly and appears to be of value; gr. $\frac{1}{3}$ in 1 c.cm. of water on alternate days for 12 doses would be a suitable course. Cacodylate of soda, gr. $\frac{1}{2}$ in ℥ x. of sterile water, may be given hypodermically daily for 20 days. Rest in bed, fresh air, and suitable climatic surroundings are essential and artificial sunlight is of value in raising the body immunity.

Blood transfusion is of great value in cases of pernicious anæmia. It helps the severe cases over the stile, so that they may afterwards receive the full benefit of the diet and medicinal and general treatment. If the hæmoglobin percentage is 40 per cent. or lower, blood transfusion should be given without delay. It is a mistake to defer the transfusion until the hæmoglobin has fallen to 30 per cent., for then one transfusion is not enough, and two or more may be required. In Sir William Willcox's experience there is no special advantage in giving immunised blood. The usual care should be taken in giving blood of appropriate grouping. A quantity of about 500 c.cm. is desirable. Sometimes after a transfusion a transient rise of temperature and a rigor may occur within 24 hours. The administration of alkalies—e.g., citrate of potash in doses of gr. 4 three times daily, for the preceding 24 hours—minimises the risk of a reaction. After a blood transfusion there is a slight rise in the hæmoglobin percentage for three or four days, and then there is a further increase. The blood transfusion acts not only as an addition of fresh hæmoglobin, but as a stimulus to the blood-forming organs. In severe cases several repetitions of the blood transfusion may be required. After the successful treatment of a case of pernicious anæmia it is most important that the patient be kept under medical observation for a long period, since remissions are of such common occurrence in this disease. Periodic blood examinations are of the utmost importance, so that any set-back may be suitably treated in its early stages.

How to Deal with Retention of Urine in an Old Man.

Mr. ZACHARY COPE said that retention of urine in an old man is most commonly due to obstruction by an enlarged adenomatous prostate, less often to malignant disease of that gland. Tabes dorsalis must be excluded and care taken to see that the condition is not one of suppression of urine. Primary atony of the bladder occurs but is rare. It is of importance to distinguish between acute and chronic retention. The chronic form may have been going on for months without symptoms or pain, the urine being passed regularly as an overflow: the kidneys are affected by the back pressure and it is then dangerous

to empty the bladder quickly. The acute form, which is painful, supervenes in a patient who looks and feels well. The practitioner should first assure himself that the retention is due to the prostate, next determine whether it is acute or chronic, then relieve the over-distension without risking injury to the kidneys by too sudden diminution of pressure. Sometimes the patient may be induced to pass water by the influence of warmth applied to the hypogastrium or perineum, or by a sitz bath. A belladonna suppository may lessen any spasm. If a catheter has to be passed scrupulous care should be taken to avoid infection. A rubber Jacques catheter can do least damage but must be well lubricated and may fail. Usually a coudé or bicoudé silk-wove gum-elastic catheter will pass; it can be boiled before use. An assistant's finger passed into the rectum may help. The urine should be let out very slowly, and in chronic cases the bladder only half emptied at the first passing. If the gum-elastic fails to pass a silver prostatic catheter should be used with extreme gentleness. When a false passage prevents anything reaching the bladder a long cannula of small bore, or a three-inch hollow needle, can be inserted into the bladder in the mid-line just above the pubes as a temporary measure of relief. After the immediate emergency has been met further over-distension is prevented by one of three measures (always presuming that the patient cannot yet pass urine naturally). (1) Repeated and regular catheterisation may be undertaken twice in the 24 hours. (2) A self-retaining catheter may be passed per urethram. (3) A self-retaining catheter can be introduced by suprapubic puncture. Repeated catheterisation is satisfactory if the doctor or a skilled nurse can do it at stated intervals with aseptic precautions. In acute attacks a self-retaining catheter inserted for a few days may tide over the time until voluntary micturition returns. A Malecot two-winged or four-winged catheter or a Dowse are more satisfactory than the ordinary de Pezzer. The catheter is passed after stretching it on a long German silver probe whose curve is easily adjusted. The probe is inserted into the catheter which is stretched till the wings are flush with the rest of the tube; it is fixed in the stretched position either (with difficulty) by the fingers or (easily) by means of Guyon's device. It is passed into the bladder and released when the stilet is withdrawn. If tolerated well it can be left in from one to seven days when the patient can often pass urine naturally. A spigot should be put in the open end and removed when urine is to be passed. If there is hæmorrhage into the bladder or if prostatectomy is to be done afterwards it is wise to put a self-retaining catheter into the bladder by the suprapubic route. This is done under local anæsthesia by the special trocar and cannula manufactured for that purpose. When called to a case of retention it is impossible for the practitioner to know beforehand what measures may be required, and Mr. Cope demonstrated a prostatic retention-case containing everything likely to be needed in an emergency, made to his requirements by the Genito-Urinary Manufacturing Company. He concluded by emphasising again the danger of emptying rapidly an over-distended bladder.

The Use of the Duodenal Tube in Gastric and Duodenal Ulcers.

Dr. ERNEST YOUNG said that duodenal feeding as a method of treatment of gastric and duodenal ulcers was introduced by Max Einhorn, of America, and has since been employed extensively by several of the leading men in that country. So far as this country is concerned, however, although the duodenal tube has been used for several years past for purposes of diagnosis, its therapeutic value for duodenal feeding in peptic ulcers has been unaccountably neglected. For the last few years Dr. Young had employed this method of treatment in most of his cases of peptic ulcers with better results than from any other form of treatment. Briefly, he said, the method consists in passing a small rubber tube with a perforated metal tip into the stomach, whence the peristalsis of the stomach gradually forces the tip of the tube through the pylorus into the duodenum. A few simple tests determine when the tube is in the duodenum, and feeding then commences, the patient receiving through the tube eight liquid feeds each day at two-hourly intervals, for the whole period of active treatment—18 days. The rationale of the method may be summed up in one word—*rest*. The stomach is out of action; no food and—what is even more important—no acid secretion passes over the ulcer, which is therefore kept free from irritation and given a chance of healing. Feeding is accomplished by means of a small irrigator, the distal end of the attached rubber tube being fitted with a graduated glass nozzle, this nozzle being connected with the proximal end of the duodenal tube when required. The duodenal tube is 47 inches in length, and is marked with black rings at 23 and 30 inches from the tip. When the tube is well into the duodenum the 30-inch mark is level with the teeth, while the tip of the tube is extended some 7 inches past the pylorus, well beyond the usual site of a duodenal ulcer. The proximal end of the tube is 17 inches outside the mouth, and when not in use is closed with a bone plug. The feeds consist alternately of 8 oz. of egg and milk and 8 oz. of Benger's food with a tablespoonful of cream. They should be given at body heat and strained through gauze to prevent any thick particles blocking the tube. After the last feed on the evening of the eighteenth day the tube is withdrawn. The next morning light solid food is commenced forthwith. Breakfast may consist of a scrambled egg, rusks, a little butter, and a teacupful of China tea. For lunch, boiled fish, sieved potato, rusks, baked custard, half a tumblerful of water. For tea, two teacupfuls of China tea and a few plain biscuits. For dinner, breast of chicken, sieved potato, rusks, junket and cream, half a tumblerful of water. One hour before breakfast, and at 10 P.M., a tumblerful of hot water. After a week or so the diet may be gradually increased and varied; thus two eggs (boiled, poached, or scrambled) or thin slices of cold boiled bacon may be taken for breakfast and stale white bread substituted for rusks; tender beef or mutton can also be taken occasionally at lunch and dinner as a change from fish or chicken, and in this way the patient may slowly return to a more or less normal diet within a month. It is well, however, for a space of three months to forbid all fruit, either raw or stewed, and to permit a second vegetable only if passed through a sieve.

Dr. Young reiterated his statement that he had obtained better results from this method than from any other therapeutic measure. Apart from this, he said, the short period required for active treatment is greatly in its favour; the patient's confinement to bed is limited to 18 days, and he may be up and about on a light diet within three weeks. Although he had followed Einhorn regarding technique, he had modified his suggestions regarding diet.

The Significance of Pain in the Lower Extremities and its Treatment.

Dr. WILFRED HARRIS said that persistent or repeated pain must not lightly be dismissed as rheumatic or as functional. The character of the pain may be a clue to diagnosis, as in the lightning pains of tabes; the distribution of the pain around the hip and groin and front of thigh will suggest arthritis of the hip, while pain shooting down the back of the thigh into the calf and ankle is characteristic of sciatica. Sciatic neuritis often, however, accompanies arthritis of the hip. Rheumatic sciatica may be mistaken for the pain produced by malignant growths in the pelvis, the distribution of the pain being identical, though a history of an antecedent breast operation may furnish the clue. Caries of the lower spine or of the pelvis may also simulate sciatica until the appearance of a cold abscess decides the diagnosis. Paroxysms of very severe pain may occur in anterior crural neuritis, of septic or diabetic origin. The pain

is here down the front of the thigh and inner side of the leg, while the knee-jerk may be lost; in sciatica the knee-jerk is unaffected, but the Achilles jerk is lost in a large proportion of cases. Herpes zoster may be a sign of central disease affecting the lower lumbar roots, and tumours of the lumbo-sacral region of the cord may cause perplexing pain until the appearance of anæsthesia, muscular wasting, and alteration of the reflexes. Chronic vascular disease, thrombo-angiitis, and endarteritis obliterans, perhaps complicating diabetes, may cause intense wearing pain, but should be easily recognised by changes in colour and loss of arterial pulsation. Some cases are much benefited by periarterial sympathectomy. Sciatica and many chronic pains may be relieved temporarily and sleep obtained with the aid of linseed and mustard poultices; the mustard must be weak. Acute sciatica may be temporarily much relieved by subcutaneous injection of oxygen along the upper course of the nerve, while chronic cases are frequently cured by two or three intraneural injections of 60 to 80 c.cm. of sterilised saline at the sciatic notch and infra-gluteal fold.

LESSONS FROM LIFE-TABLES.

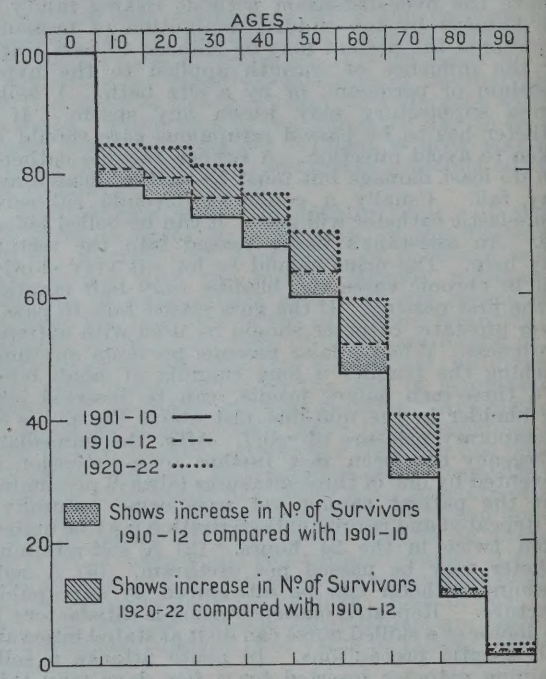
SOME POINTS FROM THE REGISTRAR-GENERAL'S DECENNIAL SUPPLEMENT.

IN a previous article (THE LANCET, Oct. 1st, p. 715) attention has already been drawn to Part I. of this Supplement, which is concerned with national life-tables; and the remarkable increase in expectation of life has been emphasised. On this point a further illustration may be adduced. Taking England and Wales as a whole, the expectation of life at birth for males has increased by 7·09 years, and for females by 7·20 years between 1901–10 and 1920–22. But when the rural districts of the eastern counties are contrasted with the county boroughs of Northumberland and Durham, on the basis of the recent experience of 1920–22, there is a difference of average years of life in favour of the eastern counties of 12·74 years for male children at birth and of 10·43 years for female children at birth. It is evident therefore that the possibilities of large further improvements in average duration of life are far from being exhausted.

The statement of number of survivors at different ages out of a given number born shows for a life-table population the actual number of added years of life at each period of life. For males, Fig. 1 shows the saving in each decade of life when the life-table experience—i.e., the experience of 100,000 males followed from birth to extinction—during 1901–10 is compared with that of 1910–12, and when the experience of 1910–12 is compared with that of 1920–22. There has been gain in years of life at all ages in both the two more recent periods, the gain being greater at every age in 1920–22 than in 1910–12. Furthermore, the greatest part of this gain has been secured at the working years of life from 20 onwards. Even the older ages, from 70 onwards, have shared the gain in vitality, though to a smaller degree. Another view of the same events is illustrated in Fig. 2, in which the difference for any age in probability of surviving ten years is shown in the experience of the three life-tables under comparison. The differences on the scale adopted do not appear so striking as those in Fig. 1, which represent the accumulated advantages at any age from all lower ages; but they are nevertheless very important. The greatest improvement in the prospect of surviving ten years is, as might have been anticipated, at birth. The probability of a child dying in the first year of age has decreased 40 per cent. in 15 years. At age 10 both recent periods show improvement over 1901–10, but there is little difference between 1910–12 and 1920–22. At age 20 there is no marked difference between the three periods. At ages 30, 40, 50, 60, and 70 marked improvements are shown.

From the point of view of public health possibilities great interest attaches to the comparison in the life-table report between the experience of the county

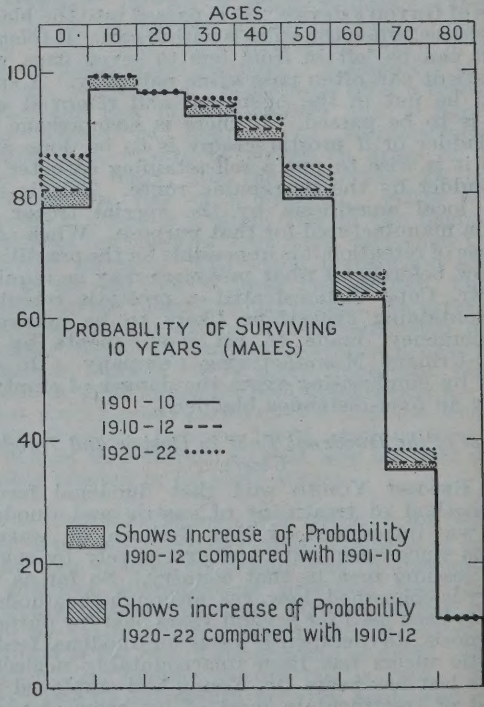
FIG. 1.



Number of survivors (males) out of 100,000 born in accordance with the experience of 1901–10, 1910–12, 1920–22.

boroughs in the counties of Northumberland and Durham and that of the rural districts of the eastern counties of England. The results are shown for males and females respectively in Figs. 3 and 4.

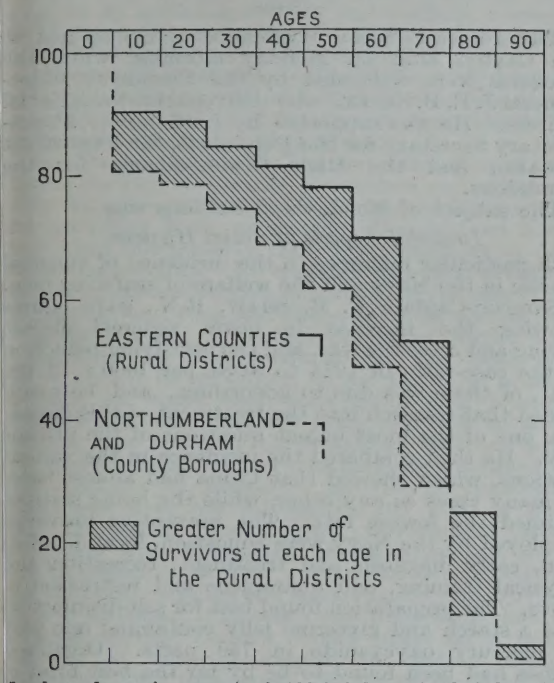
FIG. 2.



In Fig. 3 are given the number of survivors out o 100,000 male children born, according to the experi ence of deaths, in 1920–22, in the urban and rura

parts under comparison. The steps of the lower curve show the experience of favourably placed rural counties. They do not represent the best attainable

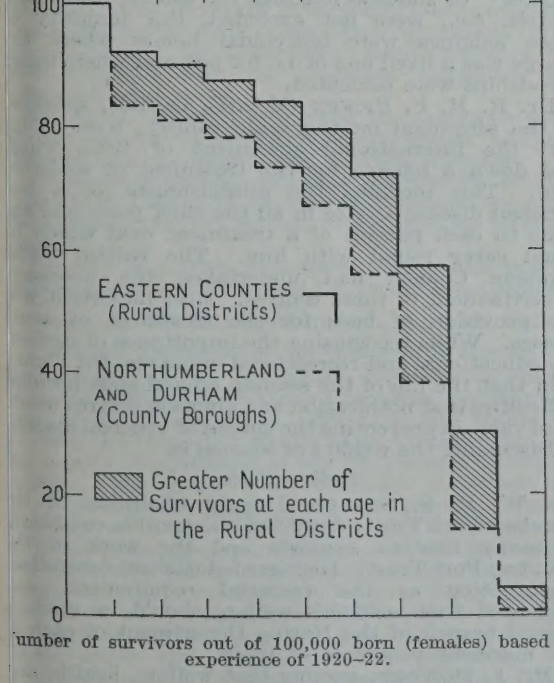
FIG. 3.



Number of survivors out of 100,000 born (males) based on experience of 1920–22.

position, for a large part of this rural mortality at successive ages is preventable—that is, it might, in more favourable circumstances, be postponed to

FIG. 4.



Number of survivors out of 100,000 born (females) based on experience of 1920–22.

later ages. But the steps in the upper curve show for densely populated industrial towns the distance still to be travelled before the relatively favourable position of the rural counties is reached. That much, probably the greater part, of this gap can be closed up is practically certain. Fig. 4 shows that the gap is slightly less for females than for males; but the gap is there, and it is evident that both in domestic life and in industrial circumstances there are insanitary and antisocial conditions which militate against health. There are strong *a priori* grounds for the conclusion that climatic differences are not chiefly responsible; and there is evident scope for more detailed investigation and analysis of the vital statistics concerned, and for the application of the social and sanitary measures of amelioration and prevention which such increased knowledge would make at once applicable.

Sir Alfred Watson has made some interesting observations on the differences between rural and urban mortality. He draws attention to the too neglected fact that occupational and industrial conditions do not suffice to explain the facts, though they are important. The female death-rates in the urban areas specially considered are also high, though not quite so high as those of males, in the areas of excessive mortality. There is needed a further study of the total conditions of mortality in special industrial areas to throw light on this problem.

One elusive element consists in the specially low death-rate of males in rural areas. This is explicable largely by their outdoor occupations, and this explanation throws some light on the relatively less favourable mortality of females in rural districts in early adult life. The greater migration of young women than of young men to towns also bears part in this result.

Another interesting problem arises out of the fact that at the years of life from 18 to 27 inclusive, the death-rate for females is appreciably higher in 1920–22 than in 1910–12. Not only so, but in the central counties of England from ages 16 to 28 the female death-rate in the rural districts was higher than that of the county boroughs. This result must be attributable largely to migration of the stronger women to towns; but inasmuch as tuberculosis contributes some 40 per cent. to the total deaths at these ages, it is likely that more successful and complete methods of dealing with this disease in towns accounts for some of the difference. The problem of tuberculosis in relation to the retardation of reduction of death-rate in early adult life is suggested for further inquiry by Sir Alfred Watson, and it is to be hoped that it will be made the subject of careful statistical investigation.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Royal Sanitary Association of Scotland.

THE Royal Sanitary Association of Scotland, which has just held its fifty-third annual meeting, began almost with the beginnings of the public health movement in the north. It has steadily increased in membership and influence until to-day it may fairly be called an unofficial sanitary parliament of Scotland. Its council includes representatives of all the grades and varieties of officers engaged in public health administration, central and local, together with unofficial members and representatives of local authorities. The congresses, as a rule, are attended by delegates from every important area and the discussions may fairly be taken as showing an enlightenment of public opinion. Other associations, such as the Health Visitors and the Insurance Committee Associations, have crept up meanwhile and have secured special places on the fringes of the official administration; but none of them has quite the place of the Royal Sanitary Association, which not only discusses policy, but is also an examining body and has an official place in the central examination committee for health visitors.

At the recent Inverness meeting the "popular lecture" was given by Prof. J. R. Currie, who dealt

primarily with pestilence and showed how the advance of hygiene depends ultimately on a growing consciousness of the importance of air, light, and sports, on the facilities for securing them, and on the education of the public. Dr. A. S. M. Macgregor presided over the meeting and added another to the many well-loaded papers contributed to the Association by his predecessors in the office of medical officer of health for Glasgow, Dr. J. Burn Russell and Dr. A. K. Chalmers. It seems to-day barely credible that Sir William Gairdner, Russell's predecessor, was actually the first medical officer of health of Glasgow, so young is this great movement. He was one of the great heart specialists and now, by a very circuitous route, we are coming back through "the prevention of rheumatism" agitation to the point where Gairdner's clinical insight would be of profound value to the health authorities—which in his official days were only beginning to clean their dirty courts and to tackle typhus seriously.

Dr. Parlane Kinloch, M.O.H. for Aberdeen, opened a discussion on local authority hospitals. This is rapidly becoming a living issue, and I notice that one of the planks in the Labour platform at the coming Edinburgh municipal election is a new municipal hospital. This has a special interest at the moment, for it has been announced that the fine hospital at Craigleith, which has been occupied for national purposes ever since the beginning of the war, is to be handed back by the Ministry of Pensions to the parish council next Whitsun. Obviously, this hospital is likely to be a precipitation point for ideas on hospital reorganisation, especially now that reform of the Poor-law is at last passing on to the plane of practical politics.

There was a good discussion on the working of the Tuberculosis Order of 1925. Mr. Trotter (Glasgow) moved that the conference, being of opinion that the Tuberculosis Order did not ensure complete protection to consumers of milk from infection by bovine tuberculosis, resolve to request the Ministry of Agriculture to take steps as may be necessary to educate stock-owners as to the necessity of conducting methods for the eradication of bovine tuberculosis and to inaugurate a scheme for the assistance of stock-owners who would voluntarily adopt eradication methods, the Ministry to provide the necessary facilities. Dr. Gerald Leighton, medical officer (foods), Scottish Board of Health, said that the great majority of local authorities, and especially those in the milk-producing areas, were doing splendid work under the provisions of both the Order and the Dairies Act. So far as he was able to judge, the milk-supply as a whole was improving more rapidly than it had ever done before and was certainly much better to-day than ever it was.

The inevitable discussion on the housing problem showed that Scotland is at last awake to its vastness and importance.

THE "MEDICAL OFFICER."—On Saturday, Sept. 24th, Mr. George S. Elliston, the editor of the "Medical Officer," gave an informal dinner at the Criterion Restaurant to the "Friends of the Journal" to celebrate the 1000th issue of the paper. A large part of the Council of the Society of Medical Officers of Health were present, the Principal Medical Officer of the Ministry of Health, the principal officials of the British Medical Association, and the editors of the medical journals, and all united in congratulating Mr. Elliston on his valuable work, and in wishing him success in conducting the "Medical Officer," and the further literary work which he has in contemplation.

MERSEYSIDE VOLUNTARY HOSPITALS.—A conference of representatives of Merseyside Voluntary Hospitals has been held to consider a development of the system of 1*d.* in the £ contributions. The purpose in view is to meet the needs of the whole of the Merseyside hospitals, and to give the managing authorities an opportunity to invite firms and organised labour to participate more generally in the scheme. Mr. Sidney Lamb, Secretary of the Liverpool Hospitals Council, states that the 1*d.* in the £ scheme is steadily growing—the increase in the council's income being £3500 in excess of the amount a year ago.

THE PROBLEM OF VENEREAL DISEASE.

IMPERIAL SOCIAL HYGIENE CONGRESS,

WESTMINSTER, OCT. 3RD–7TH.

THE Imperial Social Hygiene Congress opened at the Caxton Hall on Monday morning, when the delegates were welcomed by the President, Major-General J. E. B. SEELY, who delivered his Presidential address. He was supported by Lord LOVAT, Parliamentary Secretary for the Dominions, Sir FREDERICK LUGARD, and the High Commissioners for the Dominions.

The subject of Monday's discussions was

Imperial Aspects of Social Hygiene,

with particular reference to the incidence of venereal disease in the Navy and the welfare of seafaring men.

Surgeon-Captain T. B. SHAW, R.N., gave figures showing the increase in naval venereal disease during and after the war, and the gratifying reduction of the case-ratio in 1924 to 81·84 per 1000; 72 per cent. of these was due to gonorrhœa, and he maintained that research into the treatment of this disease was one of the most urgent questions of the present day. He then compared the incidence in the various stations, which showed that China had almost twice as many cases as any other, while the home stations claimed the lowest rate. The preventive measures employed by the Navy were education, local disinfection, early diagnosis and treatment, recreation and physical training, and quarantine and restriction of leave. The preparation found best for self-disinfection was a starch and glycerine jelly containing one part of mercury oxycyanide in 750 parts. Organised games had been found to be by far the best form of physical training, and the Navy Handbook listed no fewer than 57 games which could be played on board with little or no apparatus. He urged the formation of a Mercantile Marine Sports Board on the lines of the R.N. and R.M. Sports Control Board, and described the tremendous improvement in the conduct of sailors since the inauguration of the "Cruising Club," which provided a club building at ports where sailors' institutes and other amenities were not available. In close connexion with this was the "accommodation register" of suitable lodgings for sailors. Although hostels, &c., were not excluded, the majority of these lodgings were individual homes where the charge was a fixed one of 1*s.* for bed and where many friendships were cemented.

Dr. R. M. F. PICKEN (M.O.H., Cardiff), speaking in the afternoon on the same subject, took as his text the international agreement of 1925, which laid down a scheme for the treatment of seafaring men. This included the establishment of a free venereal disease service in all the chief ports and the issue to each patient of a treatment card which he could carry round with him. The British Social Hygiene Council had undertaken the necessary advertisement of these centres. Most important was the provision of beds for the treatment of acute phases. While recognising the importance of perfecting educational and recreational measures, Dr. Picken held that the life of the seaman offered such peculiar difficulties that notification and ablution centres would be of value in preventing the spread of venereal disease.

Discussing the welfare of seamen in

Indian Ports,

Mr. W. R. S. SHARPE (Deputy Chairman of the Bombay Port Trust) described the terrible conditions of many Eastern seaports and the work of the Bombay Port Trust. He regarded efficient centralised organisation as the essential requirement, and suggested that seamen's welfare should be made a special branch of the Marine Department of each of the maritime provinces of India.

Mr. L. BOWDEN, arguing that welfare, health, and port conditions should be a matter for international convention, pointed out that regulations suitable for shore populations rarely suited the seaman. It was

the work of insurance to prevent disease as well as to provide medical care ashore, welfare centres in the ports of the world, and treatment afloat. He suggested that the work should be organised by the League of Nations, a proportionate premium being paid by all maritime nations, and outlined a scheme. Most merchant seamen went to sea during adolescence, when life-long habits were being formed.

Sir GEORGE BUCHANAN outlined the work done and in contemplation, and said that it was essential to provide in every port treatment that should be gratuitous, modern, and continuous.

Dr. DAVID LEES said that the difficulties of combining the two viewpoints, prevention and treatment, were often exaggerated. He emphasised the necessity for providing beds, as seamen often had no homes and could not possibly carry out treatment in doss-houses or lodgings. He criticised the lack of interest shown by medical officers in writing up the case-sheets of seamen, and proposed that the forms should have a space wherein each medical officer might write suggestions for the treatment at the next port. There should be an officer, of the nature of a senior orderly, on board each ship doing long journeys, supplied with the requisite drugs and able to advise seamen how to carry on treatment between ports. At present there was no intermediate treatment for the majority of patients. Sir George Buchanan's conditions were not fulfilled in any port in India, and he hoped the Central Government would coöperate with provincial governments and see to the provision of outdoor and indoor accommodation for European seamen and lascars and to the provision of free salvarsan. It was most important that the General Medical Council should insist on a proper training in venereal disease for Indian medical students; only thus would the quack be eliminated.

Dr. A. O. ROSS described the work in Liverpool; an enormous increase of attendances had followed the extension of clinics to seamen. All incoming ships were visited and the captain asked to provide a list of his men suffering from venereal disease. They were then seen and advised to attend the Seamen's Dispensary; if they did not report within 24 hours they were again visited by the port sanitary inspector. Two-thirds of them attended. The Ship Captains' Medical Diary badly needed revision. Intermediate treatment was certainly most important; salvarsan was a dangerous drug when given irregularly. The syringe should be abolished; many patients had been supplied with an irrigation apparatus and solution for use at sea.

Mr. E. B. TURNER recounted the measures taken by the General Medical Council to ensure adequate training and examination in venereal diseases.

The chair at this meeting was taken by Sir BURTON HADWICK, Company of Master Mariners, owing to the absence, through illness, of Admiral Sir Reginald Tupper.

Tuesday morning's discussion was on the medical aspects of social hygiene, and Dr. DAVID LEES presided.

Colonel L. W. HARRISON read a paper on the

Modern Treatment of Syphilis and its Results.

He commented on the great diversity of opinion as to the amount of treatment required, and the best form of giving the drugs. He then laid before the meeting the tabulated results of an investigation into the results of treatment at the St. Thomas's Hospital Centre. The cases were carefully classified into (1) sero-negative primary, (2) sero-positive primary, (3) early secondary with roseola, (4) late secondary with lenticulo-papular eruptions, and (5) late stages, and were also grouped according to the amount of treatment they received. Serum results showed that there was no appreciable difference between the varieties of "914," nor did bismuth in the early stages show any superiority over mercury. Its action seemed to be that of preventing the tissues from reacting to the spirochæte. His conclusions were: (1) it was most important to start treatment before the serum reactions become positive; (2) the minimum amount of treatment for a sero-negative primary case was 20 injections, totalling 10–12 g. of "914" with mercury or bismuth, and for sero-positive primary and early secondary cases quite 50 per cent. more; (3) bismuth was not a substitute for arsenobenzol in early cases, and its main superiority over mercury lay in its tolerability; (4) the method of administering mercury or bismuth simultaneously with arsenobenzol had advantages over that of following a course of one with a course of the other, especially from the point of view of preventing neuro-recurrences; (5) the coincidence of negative serum reactions with positive cerebro-spinal fluid was so uncommon and the inconveniences attending lumbar puncture were so great that in cases which had run a straightforward and satisfactory course from the serological point of view routine examinations of the cerebro-spinal fluid might safely be omitted.

Prof. F. J. BROWNE, in a paper on the

Management of Cases of Venereal Disease in Antenatal and Postnatal Clinics,

said that in an ordinary clinic the frequency of syphilis was about 7 per cent. In discussing the *diagnosis* he remarked on the difficulty of getting a syphilitic history from multiparæ, on the importance of searching both the patient and her story carefully for suspicious signs, on the value of the positive Wassermann and on the necessity for examining the products of conception. Evidence of syphilis should be sought in the placenta, the cord, and the fœtus. A final test, where others failed, was the "therapeutic"—i.e., giving a patient with a suspicious history a course of antisyphilitic treatment. If this resulted in the birth of a healthy child the case might be regarded as one of latent syphilis.

Treatment should begin as early as possible, preferably before conception, and should continue throughout every pregnancy up to the time of confinement. Drugs should not be combined on account of the danger of kidney damage; arsenic was less dangerous than bismuth and mercury, but in the absence of albuminuria they might be given alternately. The best results followed six or eight weekly intravenous novarsenobenzol injections followed by a month's interval, during which intramuscular grey oil was given weekly. These courses should be continued for at least 18 months, or up to a year after all tests were negative. The only proof of cure was reinfection. *Gonorrhœa* did not often take an acute form in pregnancy. The subacute forms could only be detected by careful examination, in the lithotomy position, of the whole genital tract. The discharge could usually be cleared up in a few weeks by bi-weekly swabbing of the cervix, preceded by cleansing with sodium bicarbonate to remove mucus. Many preparations could be used, but saline solution gave equally good results. An astringent dusting powder should be used on cervix and vagina after the swabbing. Detoxicated vaccines were helpful. Douching had no place in pregnancy and all handling must be very careful. Treatment should be continued until all clinical evidence of disease had been eradicated.

After outlining the treatment of venereal diseases in pregnancy, Prof. BROWNE laid down a number of principles which included a routine Wassermann and the provision of antenatal beds, and a venereal centre in the maternity hospital, with treatment by a woman expert. Under no circumstances should any part of the machinery be labelled "V.D.," and all vaginal discharges should be treated in the clinic. Coöperation with a skilled pathologist, the child welfare medical officers, the general venereal disease clinic, the husband, and a special "follow-up" nurse was essential to the scheme. He advocated the compulsory notification of pregnancy at the third or fourth month.

Dr. MARGARET RORKE urged full arsenical and bismuth treatment for the syphilitic woman in pregnancy. In pregnancies subsequent to a thorough

course, lesser doses might be given, unless the husband had failed to pursue his treatment. A common and tiresome complication of gonorrhœa in pregnancy was the superimposition of an acute *B. coli* infection. Acute urethritis was another dangerous complication; diathermy during pregnancy had given satisfactory results. Where antenatal and baby clinics were some distance from the venereal disease centre it would be helpful if a venereal disease medical officer could attend weekly or fortnightly.

Dr. A. O. ROSS said that intensive treatment (e.g., bi-weekly injections of N.A.B. and bismuth for four to six weeks) gave a high cure-ratio. Cases remained sero-negative for at least three months after it; 98 per cent. of sero-positive cases, infected for two years or less, became negative; and 72 per cent. of those infected more than two years showed a negative result three months after a course of treatment. It was essenital that the treatment be absolutely regular.

Dr. A. CAMPBELL emphasised the necessity of repeated Wassermann tests. He gave 27 doses of neosalvarsan in a year's course; quite a number of patients relapsed three months after the course ceased. In the second year he gave large doses of mercury. Many cases were arsenic-fast to begin with; they might have been infected by a person who had received arsenical treatment. For this reason it was wise to change from one variety of arsenic to another. He was convinced that we were paying the penalty, in our large number of neuro-syphilitics, for the very small doses of mercury which had been in vogue just before the introduction of arsenic.

Colonel HARRISON quoted an investigation into 280 women who showed absolutely no signs of syphilis; 40 of them had proved to have positive Wassermann reactions. One child of twins might be syphilitic and the other healthy. He pleaded for closer liaison between child welfare and venereal departments; where venereal treatment had been provided at maternity centres it had been most successful, and he hoped the practice would be extended. Both he and Dr. Lees drew attention to the great importance of antenatal treatment of gonorrhœa.

Dr. LEES said that syphilis was grossly under-treated in this country, and in India the average amount of treatment given was appalling. Steps should be taken to control bismuth as arsenobenzol was controlled, and to stop the alluring and misleading advertisements of new and untested preparations, the only result of which was neuro-recurrence. Dual therapy was more potent than monotherapy, and he had found it possible to give bismuth and arsenobenzol together to pregnant women. Arsenic and bismuth were better and more tolerable than arsenic and mercury. He urged the importance of routine dental and post-puerperal examinations of all cases. While disappointed by diathermy for gonorrhœal urethritis, he had had good results from protein shock and local vaccine spraying. The urethra was very deceptive and might often be passed as cured when careful bacteriological inspection would reveal an infection.

The Congress Dinner was held at the Hotel Cecil on Monday evening, when Major-General J. E. B. Seely was supported by Sir Burton Chadwick, Sir Walter Willson, Sir William Schooling, Prof. Winifred Cullis, Mr. E. B. Turner, and others. The Minister of Health, proposing the toast of "Health and Empire," outlined the work of the Ministry in promoting imperial health, mentioning the establishment of the London School of Tropical Medicine and Hygiene, and the Post-Graduate Medical School at the West London Hospital. He urged local authorities to realise the true economy of contributing from the rates to the work of the British Social Hygiene Council.

Further meetings of the Congress this week will deal with health in India and the Colonies, and with the educational and administrative aspects of social hygiene.

LONDON MEDICAL EXHIBITION.

THIS exhibition, which opened at the Central Hall, Westminster, S.W., on Oct. 3rd, and which closes to-day (Friday), is the largest that has been held since the inception of these exhibitions in 1905, every available inch of space in the upper and lower halls being occupied, while the attendance, both of home and overseas doctors, has been particularly good. The exhibition may now be said to cover the whole range of medical and surgical treatment, and is a useful means of keeping the busy practitioner and the post-graduate student abreast of the new drugs and appliances which follow in the wake of progressive medical research.

DRUGS AND PHARMACEUTICAL PREPARATIONS.

BURROUGHS WELLCOME AND CO. (Snow Hill-buildings, London) exhibited many scientific products of particular interest and service to the medical practitioner. A feature of the stall was the display of the causative micro-organisms of such diseases as tetanus, pneumonia, leprosy, syphilis, gonorrhœa, influenza, and diphtheria, shown by coloured transparencies, and the various medicaments used in the treatment of the diseases in association. Products which attracted special attention were Anti-Gas-Gangrene Serum (*B. welchii*) for treatment of toxæmia associated with acute intestinal obstruction, and peritonitis with ileus. Three important products for the treatment of leprosy shown were "Moogrol," a mixture of esters of acids of the chaulmoogric series; "Avenyl," for use in leprosy complicated with syphilis; and "Alepol," which marks another advance in leprology, presenting, as it does, a fraction (low melting point) of the total fatty acids of hydnocarpus oil. Salicin, which is of great interest at the moment owing to the fact that it is found to reduce temperature in cases in which quinine, salines, and other methods have failed, was presented as "Tabloid" Salicin gr. 5 and 0·25 g. Another item of interest at this stall was Irradiated Ergosterol, which, in view of the increasing importance attached to vitamin containing products, is of interest in that it offers a method of supplementing "Kepler" Cod Liver Oil in those cases where intensification of treatment is needed.—BOOTS PURE DRUG COMPANY, LTD. (Nottingham), had several additions to their large list of scientific products, a notable feature being a large container of synthetic Thyroxile actually manufactured in Nottingham, with a chart showing the various stages of preparation. Hexyl-Resorcinol Boots, hitherto issued only in capsules, was in tablet form, and Cholumbrin—critically purified Sodium Tetra - Iodo - Phenolphthalein — was exhibited in specially coated capsules, to ensure the highest percentage of positive results. Acriflavine (Boots) and a long series of pharmaceutical products of the antiseptic were prominently displayed, including a sterile emulsion which offers many advantages in surgery over the aqueous solution. Specific treatment products, embracing Stabilarsan, Sulphostab, Bismostab, Gonococcal Vaccines (St. Thomas's), and Thiosta were also shown.—ALLEN AND HANBURYS, LTD. (37, Lombard-street, London), had a very attractive exhibit of dietetic and pharmaceutical preparations among them being Perfected Cod Liver Oil, Liquid Beef, Bynotone, a nutrient consisting of red bone marrow, hæmoglobin, yeast nuclein and malt extract and foods for infants. Particular attention was called to the Iodolysin preparations used in the treatment of rheumatism, rheumatoid arthritis, and other diseases, iodolysin being a soluble compound of Thiosinamin containing 47 per cent. of iodine.—On the stall of OPPENHEIMER, SON AND CO., LTD. (179, Queen Victoria-street, London), was an instructive display of Bipalatinoids, "Oscols" for the administration of colloidal therapy, and "Pulverettes," or powder pills, as well as the Palatinoid form of administering hormone products. Much interest was shown in the "Aeriser" made by this firm, drugs by its means

being introduced into the air passages in a state of extremely fine division—an almost invisible vapour.—Particularly prominent on the stall of SAVORY AND MOORE, LTD. (143, New Bond-street, London), were pictures of children showing the value of the food preparation for which this firm is well known. Other exhibits were Peptonised Cocoa and Milk, Peptonised Milk, and many pharmaceutical products elegantly prepared.—CHAS. ZIMMERMANN AND CO (CHEMICALS), LTD. (9–10, St. Mary-at-Hill, London), drew attention to Asthmolysin (Weiss), a standardised suprarenal pituitary compound for hypodermic use in bronchial asthma, and to Angiolymphe (Rous) for intramuscular injection in tuberculosis.

W. MARTINDALE (10, New Cavendish-street, London) again exhibited a very wide selection of pharmaceutical preparations, prominent among them being "Bromo-Ray" (Sodium Tetrabromphenolphthalein) and "Iodo-Ray" (Sodium Tetraiodophenolphthalein) for use in cholecystography. Attention was also called to Methyl-Aspriodine for inunction in acute and chronic rheumatic affections.—MENLEY AND JAMES (64, Hatton-garden, London) showed Iodex products, including liquid Iodex, and new preparations, including Vitaminose (Vitamin Chlorophyll Compound).—C. J. HEWLETT AND SON, LTD. (35–42, Charlotte-street, and Curtain-road, London), presented a wide range of "Colloigen" preparations—Alumnia, Argentum, Calcium, Iodine, and Sulphur—and many drugs and chemicals, and surgical instruments.—MAY AND BAKER (Battersea and Wandsworth, London), in their large display of pharmaceutical preparations, included Metarsenobillon, a water-soluble arsenobenzene derivative for subcutaneous or intramuscular injections, Thallium Acetate for oral administration for the epilation of the scalp in the treatment of ringworm, and Opacin for cholecystography orally or by intravenous injection, and Ephedrine, whose action is similar to that of adrenalin, but claimed to be more lasting.—Quite a large amount of interest was shown in the stall of H. R. NAPP, LTD. (3–4, Clement's-inn, Kingsway, London), who, among their many medical preparations, showed Cardiazol, a restorative which is claimed to be more efficacious than camphor, and completely soluble in water; Ephetonin, to replace adrenalin in bronchial asthma and hypotonia; Vigantol, 4 centigrammes of which equals 2 gallons of cod-liver oil in antirachitic treatment, was also prominently exhibited, the vitamin D content being particularly emphasised.—BAYER PRODUCTS, LTD. (19, St. Dunstan's-hill, London), had a special exhibit of Vigantol, the new D-vitamin product, which was the centre of a constant stream of visitors.—In connexion with the increasing interest in vitamin D it may be mentioned that a special set of apparatus for vitamin test, as used by the National Council of Medical Research Laboratories, was shown by the TINTOMETER, LTD. (Colour Laboratory, Salisbury).

PARKE, DAVIS AND CO. (50, Beak-street, Regent-street, London) showed a fine selection of pharmaceutical specialties and biological products, prominent among them being Chloretone Inhalant, a combination of camphor, chloretone, and menthol in a base of liquid petroleum, Immunogens, a new series of soluble bacterial antigens, and Sanocrysin (AuS_2O_3)$2Na_3$ for the treatment of certain forms of tuberculosis.—MODERN PHARMACALS, LTD. (2, Calthorpe-street, London), showed Sulfarsenol, and E. H. SPICER AND CO., LTD. (72, Wigmore-street, London), exhibited the Bacillus Acidophilus Emulsion, of which they are the manufacturers, and the "Homburg" pharmaceutical specialties, including Transpulmin, a combination of quinine and camphor in ethereal oils which provides painless means for the injection of quinine, and which is indicated in influenza, bronchitis, and pneumonia; Spirobismol, a chemically soluble potassium-sodium-bismuthyl tartrate and insoluble quinine-iodide-bismuth, finely distributed in an oily suspension, including a small quantity of camphor, for use in syphilis, and Treupel Tablets, an anodyne and antipyretic.—HOWARDS AND SONS, LTD. (Ilford, near London), made prominent the Agotan brand of Phenylcinchoninic Acid for rheumatism, gout, brachial neuritis, neuralgia, and other affections, while Agotan ointment, together with Howard's Standard Ether, was also shown.—GENATOSAN, LTD. (Loughborough, Leicestershire), exhibited Sanatogen, Formamint, Genasprin, Cystopurin, a urinary antiseptic, Nasmint, a germ-killing snuff, and a wide range of vaccines.—SCHERING, LTD. (3, Lloyd's-avenue, London), presented Veramon, an analgesic which relieves pain without inducing sleep, is not habit-forming, and it is claimed to be an efficient substitute for morphia treatment; Medinal, a rapidly acting hypnotic and sedative; Neutralon for the treatment of hypersecretion, hyperchlorhydria, and gastric and duodenal ulcers consequent on hyperacidity, and Atophan a uric acid eliminant.—TETMAL, LTD. (45, Farringdon-street, London), who exhibited their preparation, Tetmal, demonstrated its use as an analgesic and antipyretic, and also called attention to Codlivex, a confection containing the lipoid of the liver, one tablet being equivalent to one tablespoonful of cod-liver oil.—THE BRITISH ALKALOIDS, LTD. (104, Winchester House), staged T.C.P. (Trichlorophenylmethyliodosalicylic acid in H_2O), a non-caustic and non-toxic Germicide, which, in addition to its destructive action on noxious germs, is claimed to have a vitalising action on leucocytes.—BARNOLD, LTD. (7 and 8, Milverton-street, London), had an exhibit showing Tabelle Cerevisiæ Compound (yeast with glycerophosphates) prepared to meet the demand for a standard yeast tablet, and Oracton Tonic Food Squares containing milk with calcium glycerophosphate.—BRISTOL-MYERS CO. (112, Cheapside, London) made prominent Sal Hepatica, an effervescent saline combination containing the principal medical salts which are found in the natural mineral waters of Europe and fortified with sodium phosphate. Ipana tooth-paste containing Ziratol, a hæmostatic antiseptic, was another exhibit of this firm.—J. C. ENO, LTD. (Pomeroy-street, London), showed the well-known "fruit" salt which may be taken during effervescence or after effervescence has subsided.—DIMOL LABORATORIES, LTD. (40, Ludgate-hill, London), displayed Dimol, which, prepared in the form of pulverettes and also in the form of syrup, pastilles, lavage powder, ointment, snuff, dentifrice, and dusting powder, is a bactericide 35 times more efficient than pure phenol. The chemical constitution of Dimol, $C_6H_2(CH_3)_2(OCH_3)OH$, reveals the presence of a phenyl radical, but this is not split off in its passage through the intestine; Dimol is voided with the fæces, unchanged. Dimol has a coefficient of 35·0 and is free from toxicity. It is indicated in the treatment of putrefactive and other bacterial invasions of the intestinal tract.—ICHTHYOL CO., LTD. (18, Adam-street, Adelphi, London), showed their product made from the raw material obtained from quarries at Seefeld in the Tyrol. It is a uniform product with a high sulphidic sulphur content.—JEYES SANITARY COMPOUNDS CO. (Victory House, 99, Regent-street, London) showed various Cyllin preparations; and NEWTON CHAMBERS AND CO., LTD. (311, Gray's Inn-road, London). Izal preparations.—MONSOL GERMICIDES, THE MOND STAFFORDSHIRE REFINING CO. (Distributors, Thomas Christy and Co., 4–12, Old Swan-lane, Upper Thames-street, London) had an attractive exhibit of this new germicide for which high efficiency is claimed, a remarkable freedom for irritant effects common to antiseptics of the phenol type, and low toxicity, together with a high degree of penetrative power. It is put up in many convenient forms, liquid, ointment, lozenges, and so forth.—THE THERMOGENE CO., LTD. (Haywards Heath, Sussex), had a fine display of their medicated wadding.—MANSONS (LONDON), LTD. (101, Hatton-garden), made a particular feature of Lipocithine as a remedy for tuberculosis, anæmia, neurasthenia, and for completing rapid convalescence.

THE HOFFMANN-LA ROCHE CHEMICAL WORKS, LTD. (51, Bowes-road, London), drew attention to their

preparation Allonal (Allyl-isopropyl-barbiturate of pheny ldimethyl-dimethylamino-pyrazolon) a synthetic non-habit-forming hypnotic and analgesic which relieves pain of all kinds and gives sleep, and to Isacen (diacetyl-di-hydroxyphenyl-isatin) a tasteless, odourless, non-toxic aperient, which is agreeable to take and safe and mild in action.—BENGUE AND CO., LTD. (24, Fitzroy-street, London), had an attractive exhibit which included Muthanol, a suspension of bismuth hydroxide and mesothorium bromide in sterile olive oil, a radio-active spirillicide, Euphorian Ampoules, entero-antigens, a polyvalent coliform vaccine, prepared from the intestinal flora, for chronic non-contagious diseases, Arhemapectyl, a new blood coagulant, and Vittel Natural Mineral Water (Grande Source) imported from the spa.—THE SANDOZ CHEMICAL WORKS (5, Wigmore-street, London) called attention to their Calcium Sandoz produce from glucose, which is readily absorbed and assimilated and can be given by the mouth intravenously or intramuscularly. Femergin (ergotamine tartrate) the active specific alkaloid of ergot of rye, Lobelin for the relief of grave respiratory troubles of central origin, and Scillaren, the pure stable cardio-active and diuretic glucoside of squill, were also prominently exhibited.—THE SACCHARIN CORPORATION, LTD. (72, Oxford-street, London), presented their Novocain in powder, tablets, and in sterilised solution in ampoules and bottles. This preparation contains no cocaine.—JOHN MORGAN RICHARDS AND SONS, LTD. (46–47, Holborn Viaduct, London), who are the agents for McKesson and Robins, New York, showed Lactopeptine for digestive disturbances, and Antikamnia, which is analgesic, antipyretic, and anodyne, in powder and tablets.—Among the variety of Collosol preparations prepared by the CROOKES LABORATORIES (BRITISH COLLOIDS, LTD.) (22, Cheniesstreet, London), Collosol Lactalumina (colloidal aluminium hydroxide) was shown and a more recent development, the same preparation with phenolphthalein 4 gr. per ounce, Collosol Lactalumina Laxative. Collosol Cod Liver Oil Emulsion 50 per cent. was another preparation calling for notice.

ANGLO-FRENCH DRUG CO., LTD. (238A, Gray's Inn-road, London), showed special pharmaceutical preparations, Adrepatine, a pluriglandular compound for the treatment of hæmorrhoids and other pluriglandular products, as well as orargol, colloidal gold-silver for general antisepsis, internal and external.—ENDOCRINES, LTD. (72, Wigmore-street, London), in addition to their large display of endocrines, showed a number of standardised endocrine products including Anabolin which has proved successful in the treatment of hyperpiesia, and Paracalcin, a standardised parathyroid available in tablet form. Attention was also drawn to Hepatic Extract for the reduction of high blood pressure. The stall of this firm contained a large number of useful books and brochures dealing with the subject of gland treatment which were at the free disposal of medical men.—ARMOUR AND CO., LTD. (Queen's House, Kingsway, London), had a representative exhibit of endocrines and digestive ferments including corpus luteum substance, orchitic substance, suprarenal crystals, and mixed gland materials.—G. W. CARNRICK CO. (40–42, Lexington-street, London) also showed endocrine remedies. Rythmin for constipation, Mammagen for defective lactation, Viriligen for lowered vitality, Erythogen for anæmia, and Kinazyme for malnutrition being among them. A book on the subject of Organotherapy in General Practice is given free to members of the medical profession by this firm.—THE BRITISH ORGANOTHERAPY CO., LTD. (22, Golden-square, London), attracted attention by a fine display of organotherapeutical products which included "Opocaps" Lymphoid-Adrenal Co. for the symptoms resulting from influenza and infective fevers, "Opocaps" Enterostasin for chronic constipation, and "Opocaps" Plammoid Co. for the nausea and vomiting of pregnancy as well as Evatmine for asthma and urticaria.—REED AND CARNRICK (Distributing Agents: Coates and Cooper, 41, Great Tower-street, London) showed glandular preparations and pharmaceuticals, one of the most prominent of their products being Pancrobilin Brand Intestinal Digestant. Pancrobilin is a physiological product containing dehydrated bile (from pure ox-gall) in combination with the nucleo-enzymes of the pancreas, and is indicated in the treatment of all forms of constipation. Peptenzyme Digestant, which contains all the glands necessary for digestion, also received attention from many inquirers. The firm of Coates and Cooper also exhibited Salvitæ for use in disorders arising from perversions of nutrition, the claim being made that it is preferable to ordinary preparations of lithium and single salines, as the collective action of its several constituents gives a much wider scope of usefulness.

DESHELL LABORATORIES, LTD. (1–3, Brixton-road, London), exhibited in several forms Petrolagar, a palatable emulsion containing 65 per cent. of pure medicinal paraffin and 10 per cent. of prepared agar, which is the emulsifying agent, no fermentative gums or soaps being used.—On the stall of the ANGIER CHEMICAL CO. (86, Clerkenwell-road, London) the emulsion of Petroleum with Hypophosphites bearing this firm's name attracted many visitors.—Liquid paraffin preparations were represented by KAYLENE, LTD. (7, Mandeville-place, London), who showed Kaylene (Colloidal Kaolin), Kaylene-ol—an emulsoid combination of Kaylene and Colonol Liquid Paraffin, and other preparations for eliminating intestinal toxins. The same firm also exhibited Spisbrod, a Swedish health bread which contains 100 per cent. of whole-grain rye.—NUJOL LABORATORIES (Albert-street, Camden Town, London). In addition to Nujol, the well-known intestinal lubricant and Cream of Nujol with Agar, this firm showed Mistol, a combination of menthol, camphor, and eucalyptol in pure mineral oil which, used in an atomiser, brings these medicaments into intimate contact with the mucosa of the nose and throat.

(To be continued.)

Obituary.

CHARLES GEORGE MACVICKER, M.B. R.U.I.

Dr. C. G. MacVicker, who died on August 30th in a Clifton nursing home, of a generalised staphylococcal infection, at the age of 64, had been in practice at Street, Somerset, for 28 years. A native of Londonderry, he studied medicine at Edinburgh University and Queen's College, Belfast, where he took high honours, qualifying in 1891. After that his life was spent in general practice in England, first at Almondsbury, near Bristol, then at Isleham, in Cambridgeshire, and from 1899 onwards at Street. Here he held various appointments, serving as medical officer to the Street District of the Wells Union, and to the Abbey Grange School for mentally deficient children. At the time of his death he was also senior medical officer to the Butleigh Hospital. One of his most important activities was in connexion with the Somerset County Nursing Association, of which committee he was a member from its foundation. He was vice-chairman to the Parochial Church Council, a vice-president of the Church of England Men's Society, and of the Ringer's Guild, and the moving spirit in many other of the activities of the church. He was also a council school manager, served as a magistrate for some years, and as a member of the Somerset Archæological Society took a close interest in county antiquities.

A colleague writes: "Dr. MacVicker was not only a professional adviser to his patients; he was their friend, as he showed both in his kindly and solicitous care for their comfort and in his determination to give to everyone, no matter their social status, the fullest resources of his profession. Attractive in person, he looked a good deal younger than his age and had an air of kindly interest in the matter

and, and a full share of the conversational aptitude f his native land, that made him a delightful com-anion. He was a faithful and loyal friend."

In 1895 Dr. MacVicker married Marion Churchill hurchill, eldest daughter of the Rev. E. B. C. hurchill, sometime vicar of All Saints, Portsea. Of heir two surviving sons, the younger is a medical tudent.

NEWCOME WHITELAW BOURNS, M.D. BRUX.

Dr. N. W. Bourns died on Oct. 2nd at Wincanton, fter an illness of nine months. He was born at arrick-on-Shannon in 1852, and after studying at t. Bartholomew's Hospital became M.R.C.S. Eng. n 1879. At St. Bartholomew's he learnt from the enior anæsthetist, Mills, the administration in equence of nitrous oxide, ether, and chloroform, hich he adopted in hospital and private work with dmirable success and remarkable safety to patients. fter settling in South Kensington he was appointed næsthetist to the Cancer Hospital, and in 1887 ecame the first regular anæsthetist to Westminster Iospital. With these duties he combined private ractice, and his pleasing manner and address were ighly appreciated by his many patients. On etiring Dr. Bourns joined some old friends in Somerset-hire, where in the Blackmore Vale he had scope or his hobbies, particularly gardening and shooting. ome time ago an unfortunate motor accident laid im by for a year, but he recovered to enjoy life again.

WILLIAM NEWLANDS CLEMMEY, M.R.C.S. ENG.

Dr. Clemmey, who died suddenly on Sept. 27th t the age of 58, came of a family long established in Bootle, his father, Sir William Clemmey, having been wice mayor of the borough. As a student at Univer-ty College, Liverpool, he distinguished himself in natomy and surgery, and after service as house rgeon was, in 1896, appointed honorary surgeon at ie Bootle Borough Hospital. This post he held ll the day of his death, but it was not as a ecialist in surgery that Dr. Clemmey found his ief work, for he also engaged in general practice, hilst the number of his professional appointments owed how wide his interests were. He served on ie council of the Liverpool Medical Institution and ok a warm interest in everything that made for the elfare of his medical colleagues. Always a hard orker and rarely giving himself a holiday, Dr. lemmey latterly found his health failing and was mpelled to give up much of his public work. This as especially regrettable, as he had been an admirable ample of the professional man who is also a leader civic life. Spending many years on the town uncil and on the board of guardians, he was always spected for his open sincerity, and latterly he had en made a justice of the peace.

Dr. Clemmey leaves two sons, of whom one has ntered the medical profession.

ALEXANDRA DAY.—The collections on Alexandra ay in London last June amounted to £48,150, to which id to be added £1111 collected by steamship companies id £3615 of other income, making a total of £52,876. After ducting expenses there was a surplus of £44,536, which as £2619 more than last year.

NORFOLK AND NORWICH HOSPITAL.—A scheme has en drafted by which persons of limited income can be ceived as paying patients in this hospital. The plan rns upon an insurance scheme, the benefits of which may secured by means of a yearly premium of £1 10*s*. Each ember will be entitled to free in-patient and certain out-tient treatment for himself and his wife, and for children der 16. Those who join the scheme before Dec. 1st ll be entitled to treatment as soon as the department is ened. The benefits of the department are not to be ited to the insured, but if there is sufficient accommoda-n any person whose income falls within the prescribed its will be received at a stated weekly charge.

Public Health Services.

POLIOMYELITIS IN KINGSTON-UPON-HULL.

Dr. W. Allen Daley, medical officer of health for Hull, has presented to his health committee an interim report on the outbreak of acute anterior poliomyelitis and polio-encephalitis in the county borough during the last three months. The first case was notified on August 2nd, the onset having occurred on July 27th; the next notification was received on August 15th, and the third on August 16th, the onset having been on August 7th and 9th. There followed two notifications on August 17th, and one each on August 19th and 20th, all these notifications were belated, the onset having been on July 13th, 24th, and 30th, and August 3rd. This made six notifications for the week ended August 20th; in the following week seven notifications were received. On August 29th a circular letter was sent to medical practitioners in the area informing them of the prevalence of the disease, with the result that a number of cases of some weeks standing were notified within a few days. After that the lag between onset and notification was somewhat less, except for the cases where no doctor had been in attendance owing to the mildness of the onset, and notification was only made after a practitioner had been consulted because of paralysis or when a medical officer of the health department called on hearing from a health visitor or school nurse that a child had suddenly developed weakness of a limb.

Up to Oct. 1st, 88 notifications were received. In three cases the diagnosis has not been confirmed; the date of notification and onset of the remainder is as follows:—

Week ended—	Onset.	N.R.	Week ended—	Onset.	N.R.
July 16th	3	—	Sept. 3rd	11	17
,, 23rd	3	—	,, 10th	12	19
,, 30th	3	—	,, 17th	8	14
Aug. 6th	4	1	,, 24th	8	14
,, 13th	11	—	Oct. 1st	1	7
,, 20th	8	6		—	—
,, 27th	13	7		85	85

N.R. = Notification received.

The usual onset has been a complaint of headache and nausea; often with pain in the back of the neck and occasionally sore-throat. The very young children went off their food and their legs, if they had begun to walk, and showed the symptoms associated in the lay mind with "teething." The weakness of a limb was often not noticed until the child had recovered its usual health and started to walk again; the mother then observed that one of the legs was being "dragged."

Three cases proved fatal—one from the acute ascending type of the disease; the second, a man of 33 years, after an illness of three days' duration in which he showed paralysis only a few hours before death; and the third from the cerebral type of the disease. During the past two weeks an increasing number of very mild cases has been discovered, with definite paresis clearing up entirely (so far as can be ascertained by ordinary examination) within a few days. No relationship has been established between the severity of the onset and the degree of paralysis.

The cases have been distributed uniformly throughout the city; there is no special incidence among the very poor, nor are those who are particularly well-housed and well-fed exempt. One group of three patients who played together has occurred, and in one house a second child developed the disease 14 days after the onset of the first, and four days after the removal of the first case to hospital. One of the early cases is known to have been in contact at a neighbouring seaside resort with a case from Lancashire which subsequently proved fatal. Otherwise no contact between the cases and no sources of infection nor "carriers" have been discovered. The possibility of a contaminated milk-supply was negatived early in the outbreak.

The ages of the 85 cases are as under :—

Under 1 year	3	
1 year and under 2 years	16	60*
2 years " " 5 "	41	
5 " " " 10 "	15	20†
10 " " " 15 "	5	
15 " " " 20 "	2	
20 " " " 30 "	2	
30 years and upwards	1	
	85	

* Under 5 years. † Aged 5 to 15 years.

The muscles involved in the 85 genuine cases have been those of: one arm, 9; both arms, 1; one leg, 39; both legs, 25; one leg and one arm, 2; both legs and one arm, 3; both legs and both arms, 1; leg and face, 1; face, 4.

As it is unknown how long the infection remains in the throat, it was necessary, Dr. Daley writes, to decide what measure of isolation should be required. This period was fixed, without any special reason, at five weeks, and all patients were isolated at home or in hospital from the time of notification until five weeks from the onset. Patients and house contacts were advised to use throat gargles of 1 per cent. hydrogen peroxide or 1 in 500 permanganate of potassium, and this was supplied free of charge on application.

The Wassermann reaction of a convalescent adult patient being found negative, his consent was obtained to the use of his blood for the preparation of serum for the treatment of acute cases. As it was unusual to receive notifications until after the onset of definite paralysis, when serum would presumably be of little or no value, its value has not been ascertained.

Thirty-eight cases were admitted to the city hospital where in most cases the cerebro-spinal fluid was found to be under increased pressure, clear but showing an excess of globulin and of lymphocytes. The limbs were put up in the neutral position; gentle massage and muscle training were not started until all the tenderness had gone. On discharge from isolation, provision is made for their treatment under the orthopædic scheme; actinotherapy will also be used at the municipal light clinic. The improvement in the movement of the limbs as a result of simple rest and prevention of stretching has been very striking.

If, Dr. Daley concludes, the "carrier" theory of infection in this disease is correct, it is necessary to assume that during the past few months there have been many "carriers" in the city, and that the proportion of those exposed to infection who succumb to it is very small.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 24TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 125 (last week 126); scarlet fever, 1958; diphtheria, 1149; enteric fever, 91; pneumonia, 637; puerperal fever, 37; puerperal pyrexia, 108; cerebro-spinal fever, 9; acute poliomyelitis, 39; acute polio-encephalitis, 4; encephalitis lethargica, 12; dysentery, 1; ophthalmia neonatorum. 103. No case of cholera, plague, or typhus fever was notified during the week.

Eighteen cases of poliomyelitis and polio-encephalitis (taken together) were reported from the East Riding of Yorkshire, 14 of them from Kingston-upon-Hull (only 7, as noted above, in the subsequent week), the others from the rural districts of Beverley, Patrington, and Sculcoates. It must be some years since so low an incidence as 12 has been reported for encephalitis lethargica.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (0) from enteric fever, 10 (1) from measles, 4 (0) from scarlet fever, 15 (4) from whooping-cough, 33 (5) from diphtheria, 92 (9) from diarrhœa and enteritis under two years, and 42 (11) from influenza. The figures in parentheses are those for London itself. The number of stillbirths registered during the week was 264, including 38 in London.

THE BROAD ROAD OF HEALTH

To the Editor of THE LANCET.

SIR,—Thomas Carlyle in a famous dictum labelle the majority of mankind as fools, Sir Thomas Hord puts a point to this in saying that all but a few foo can secure health.

The perfect human being (physically and mentall does not exist. All of us fail more or less to reach t standard of perfect health—most of us fail lamentab —a very large proportion are suffering from organ disease, functional disorder, deformities, maldevelo ment, and malnutrition. We are, according to S Thomas Horder, all in the same category—fools the victims of mischance. We have failed to "contr the car," or to take sufficient care "at the cross-roads we have driven the machine too fast or we have h no luck. True, the road has been broad and t margin of safety in some respects wide enoug Nevertheless, Nature is actually antagonistic health, since all life is a prolonged struggle to mou the environment, or to adapt the organism to Fortunately, Nature forgives much and our reserv are often considerable.

But the net result, so far as civilised humanity concerned, is a hideous array of repair shops a mechanics, lining the roads of life and worki overtime. Sir Thomas Horder has cleverly omitt these features of the landscape from his Utopi picture. Is not the explanation to be found in t appalling ignorance on the part of the drivers of the ca of the first principles of the mechanics, requiremen and driving of their machines? Sir Thomas Hord evidently does not think so since he does not inclu a knowledge of the art of living as a means to safe He is apparently of the opinion, as are also so scientists, that unless the layman can be suppli with the whole scientific truth down to the l detail, and unless the whole body of scientific opini is in agreement as to the truth to the utterm detail, no information should be given at all. T suggestion that the Medical Research Council sho institute a special inquiry into the bread quest was met with the reply that since "Vitamin possibly consisted of several vitamins and that si some expert had discovered a toxic element in germ of cereals, it was not desirable to commend particular article of food to the public.

Meanwhile, a very large section of the public suffering from malnutrition and are totally ignor of the elementary principles of dietetics. Sir Tho Horder thinks they will be content if we refer th to his stalwarts and tell them that the physical fitn of these strenuous fellows is a "spontaneous acqu ment." Compared to the dangers of such reaction teaching any over-enthusiasm as to the virtues wholemeal bread or an over-estimation of the res of a faulty dietary are but trifles.

I am, Sir, yours faithfully,

S. HENNING BELFRAG

Gloucester-place, W., Oct. 3rd, 1927.

CANCER, ADRENALIN, AND IMMUNITY

To the Editor of THE LANCET.

SIR,—Dr. Lumsden makes the statement in letter on Cancer and Adrenalin (THE LANCET, Oct. p. 733) that the whole trend of his recent work indic that "by appropriate local treatment an ac immunity can be induced which is not local *general*," so that the animal is "immune aga subsequent inoculations of the same tumour every part of its body." I am under the impres that it has been generally known for over 20 years a tumour undergoing regression from various ca produces an immunity which is not local but gene

Dr. Lumsden cannot appreciate the significance of his wn statement when he says that "the two drawings of icroscopic specimens he (Cramer) published are such s might be obtained from certain areas in untreated mours and are to my mind quite unconvincing." his very similarity is emphasised in my paper at nsiderable length (pp. 62 and 63). The paper is, fact, entitled "The Action of Radium on Trans-lanted Mouse Tumours and its Relation to the pontaneous Arrest of Their Growth." It is stated ere that where regression is induced experimentally the tumour shows in an exaggerated form the ppearances met with in more localised areas in a nsiderable proportion of the tumours propagated." he evidence presented is interpreted as showing at the regression of a tumour under the influence radium and of adrenalin is not due entirely to a xic or lethal action on the tumour cells, but that important factor in the regression is the exaggeration a process which occurs spontaneously in a more calised form and which consists in the proliferation the connective tissue elements of the stroma. he trend of recent work on the therapeutic action radium is in the same direction.

It was in the course of these experiments that the henomenon of "immunity" was observed by me, nd I am, therefore, not likely to underrate the value this observation. The part played by the developing mmunity in the process of regression was studied in nsiderable detail by B. R. G. Russell and by W. H. oglom.

This may be a suitable opportunity to summarise ery briefly the main facts which have been established ncerning this phenomenon of immunity.

1. If a tumour regresses either spontaneously or the result of experimental applications, the animal resistant against subsequent transplantation of e same tumour and to a lesser extent of other mours. This resistance to transplantation is now nerally called "immunity."

2. The same condition can be induced by the jection of normal tissues, especially embryonic sues.

3. If a transplanted tumour has been established fore immunity is induced, the established tumour nnot be made to regress. With some strains a tardation of growth has been observed.

4. This condition of immunity does not protect animal against the genesis of a new spontaneous mour, nor can an animal with a spontaneous tumour rendered immune against the experimental nsplantation of its own tumour.

5. J. Fibiger has recently shown that animals which ve been rendered immune by the repeated injection normal tissues will develop tar tumours quite as dily as normal non-immune animals. But the tastatic spread is distinctly inhibited in the immune imals, so that in his experiments the number of mune animals with metastases was approximately e-half of the non-immune animals with metastases.

I am, Sir, yours faithfully,

W. CRAMER.

Imperial Cancer Research Fund, London, W.C. 1,
Oct. 1st, 1927.

THE LATE PROF. ADRIAN STOKES.

To the Editor of THE LANCET.

SIR,—With reference to the obituary notice of the e Prof. Adrian Stokes which appears in your issue to-day, several statements appear therein which fortunately have no historical basis as to fact, and justice both to the living and the dead I think ould be corrected.

With regard to mobile laboratories, the construction the first of these was undertaken by the Medical partment of the War Office directly after the tbreak of war in August, 1914. In that year it nctioned in battle areas north of the *Lys* and reafter was entirely responsible for the bacterio-gical investigations in Belgium of all cases in the tbreak of typhoid fever among the Belgian civilian habitants in the winter of 1914–15 in the zone occupied by the British Second Army and also by the French Army on our left flank. This laboratory was in charge of a Territorial officer who had been seconded from the 3rd City of London Field Ambulance who, later, was appointed to act as my sanitary officer and was given special authority to carry out all necessary measures for controlling and suppressing the epidemic by the Belgian Ministry of the Interior. This epidemic was considered to have terminated by the beginning of June, 1915.

The second laboratory—a converted motor caravan—was furnished by the Lister Institute who, within a week of the declaration of war, had made a collective offer of its workers for service under the War Office followed by an offer of a mobile laboratory, the latter being immediately accepted. This laboratory was in charge of Major S. D. Rowland and proceeded to France, being stationed at General Headquarters at St. Omer where it remained until its transfer to the Second Army when it was attached to No. 10 Casualty Clearing Station at Remy Siding and opened out for work early in July, 1915. It was upon the occasion of this transfer that Adrian Stokes first came to the Second Army, he being attached to Major Rowland's mobile laboratory and acting as his assistant until 1916, when Rowland was transferred at his own request to Etaples to investigate cerebro-spinal fever, subsequently contracting the disease there from which he died.

My appreciation of Stokes's services and ability was such that I had no hesitation in securing his appointment as commanding officer to succeed Rowland, this being, in fact, Stokes's first command of a mobile laboratory. (Owing to their increasing numbers, it became necessary, in 1915, to number serially the mobile laboratories. In this way the first War Office built laboratory became known as No. 4 Mobile (Hygiene) Laboratory and the Lister Institute converted caravan as No. 1 Mobile (Bacteriological) Laboratory.)

By this time some five mobile laboratories had become connected with the Second Army, and I would here say that the repeated successful detection and isolation of typhoid (and other) carriers was regarded by all of them without exception as an ordinary laboratory achievement.

In justice to all concerned I would like to make it clear beyond all doubt that Stokes was not transferred to the Second Army until *after* the termination of the epidemic. He took no part, officially or otherwise, in the operations conducted by the medical service of the Second Army, under my direction, for dealing with the typhoid epidemic amongst the civil population of Belgium which occurred in the winter of 1914–15.

The history of this epidemic remains to be written; it is the story of a grave and widespread outbreak—numbering thousands of cases—amongst the civil population of a foreign country in the occupation of allied (and British) troops in an intensely active war zone in which British medical officers were given the honour and the responsibility for conducting the whole of the operations necessary for coping with the disease. They did so successfully, and I would like to take this opportunity to make an appeal to all in possession of relevant documents and records (whether copies or originals) to communicate with me in order that some organisation might be set up for duly recording its history and noting its clinical and epidemiological lessons.

I am, Sir, yours faithfully,

ROBERT PORTER,
Maj.-Gen. (ret.); formerly Director of Medical Services, Second Army, B.E.F.

27, The Avenue, Beckenham, Kent.
Oct. 1st, 1927.

*** We have submitted Sir Robert Porter's letter to "J. A. R.," the author of the obituary of Prof. Stokes, who has sent us the reply which follows:—

"I must emphatically appeal against Sir Robert Porter's contention that the obituary notice of the late Adrian Stokes, which appeared in THE LANCET,

contained 'statements . . . which have no historical basis as to fact.' Others can bear out my narrative with regard to Stokes's discovery, essentially through his own enterprise and initiative, of the typhoid carrier in the Guards' Brigade in 1914, thereby anticipating, in fact, the functions of a mobile laboratory which was not apparently then availab e to do the work. I do not imply that Stokes instigated the creation of mobile laboratories, but merely that he 'anticipated the idea.' Nowhere do I suggest, as Sir Robert Porter seems to think, that Stokes's work in the Belgian epidemic was done during service with the Second Army. In fact, it is explicitly stated that Stokes took charge of the mobile laboratory at a later period. Nevertheless, as I worked intimately with him at the hospital at Malassise near St. Omer to which some 800 Belgian civilian cases of typhoid fever were evacuated, and as I witnessed from day to day the ready enthusiasm with which he coöperated with the officers of the Friends' Ambulance Unit and the Sanitary Officer of the Second Army, and the thoroughness with which he and his colleague, the late Cecil Clarke, worked in their laboratory to ensure that no civilian carriers should be returned to the occupied areas to cause further danger to the troops—for these reasons I do feel justified in my remarks concerning Stokes's participation in this not unimportant episode of the war. I am careful to refer to him as 'an unofficial liaison officer' for at this period, as well as later at the Casualty Clearing Station, he was (although employed in a specialist capacity) continually stimulating all those with whom he came in contact, whether civilian or military, in their joint task of helping to protect the British forces from infectious disease. The hospital at Malassise was not under the medical services of the Second Army, but it played a very important part in dealing with the typhoid epidemic amongst the civilian population in the early months of 1915. No history of that epidemic, which as Sir Robert Porter says still remains to be written, would be complete if it omitted to record in some way the valuable services of the bacteriologists at the Malassise Hospital, a unit working under the ægis, if I remember rightly, of General Headquarters. I believe the commanding officers of the hospital would be only too glad to support this opinion and hope that Sir Robert Porter will revise his verdict as to the historical inaccuracies of one who had the privilege of living in the same mess with Adrian Stokes for more than two years both before and during his service with the Second Army."

MOSQUITO CONTROL: AN HISTORICAL NOTE.

To the Editor of THE LANCET.

SIR,—To Dr. J. Balfour Kirk, medical officer of health, Port Louis, Mauritius, I owe a copy of a very interesting and thoughtful book entitled, "A Voyage to the Island of Mauritius (or Isle of France), the Isle of Bourbon, and the Cape of Good Hope, &c. With observations and Reflections upon Nature and Mankind." It was written by a French officer and my copy is a translation from the French by John Parish and is dated 1775. It takes the form of a series of letters written to friends of the author. On looking through it I came upon the following note in Letter XXV. :—

> "It has been attempted, but without success, to bring frogs here, that they might eat the eggs which the mosquito lays upon the surface of the standing waters."

At this time the edible freshwater fish, the gourami, had been imported into Mauritius from Batavia and the Chinese goldfish had also been introduced, presumably for ornamental purposes. For mosquito control, however, as the passage indicates, recourse was had to frogs, and it was not until much more than a century later that "millions" fish were brought to the island to cope with the larvæ of *Anopheles costalis* or *gambiæ*, as it is now called, and also, incidentally perhaps, for their existence was not at that time known, with those of *Anopheles funestus*, the mosquit discovered in Mauritius by Mr. Malcolm MacGreg during his entomological survey of the colony 1922–23. I am, Sir, yours faithfully,

ANDREW BALFOUR,
Director, London School of Hygiene and Tropical Medicine.

Oct. 4th, 1927.

POOR-LAW HOSPITALS.

To the Editor of THE LANCET.

SIR,—The correspondence on the above subject h been most interesting, especially the letter of D H. Bailey in your issue of Sept. 3rd, in its advocac from actual experience, of the view that an infirma benefits if its superintendent is allowed a limit outside practice. I would suggest, however, that su aspects of the infirmary as its facilities for surger research, and post-graduate work, are subsidiary the question of future status and policy. This suggest is the main issue, going to the root of t whole problem. The developments of recent yea would all seem to justify a progressive policy for t infirmaries, which implies a definite break wi tradition. Undoubtedly and of necessity with su a change, professional skill and experience as distin from purely administrative ability would rece greater recognition—although a combination of t two will probably be always the most desirable while it will be recognised in time as a function of t infirmary to help in teaching, research, &c., accordi to its scope.

Dr. Bailey, in the letter already referred to, aft describing successful efforts to popularise a particu infirmary, adds: "Of course, I am quite aw all this is illegal"! This is a cogent example of t anomalies under which the Poor-law infirma functions to-day.

I am, Sir, yours faithfully,
F. J. O'DONNELL, F.R.C.P.I.

Dublin, Oct. 3rd, 1927.

MISLEADING QUALIFICATIONS.

To the Editor of THE LANCET.

SIR,—Is anyone entitled legally or ethically to t designation of F.R.C.S. without specifying the Ro College of Surgeons of which he is a Fellow unl indeed, he be a Fellow of all three Royal College This point appears to be of ethical importance view of the countenance given by the Representat Body of the British Medical Association (see T LANCET, July 23rd, 1927, p. 188) to the publicat of names and qualifications of the medical staff therapeutic institutions. In the annual report o cottage hospital outside London, issued to the l public, qualifications of the medical staff are publis and certain of the staff have gained much public este in comparison with the others by being designa F.R.C.S., as are so designated the London consulta attached, without any specification as to their Colle the consultants only are Fellows of the Royal Coll of Surgeons of England.

I am, Sir, yours faithfully,
ETHICS

Sept. 24th, 1927.

CIVIC HONOUR FOR A MEDICAL MAN.—Dr. Rob de la Poer Beresford, of Derwent Grange, nr. Oswestry Sept. 22nd received the honorary freedom of Oswestry a scroll contained in a silver casket, in recognition o services as medical officer of health for Oswestry fo years, and as Mayor of Oswestry for two years—in and 1910.

INNOVATION AT MANCHESTER INFIRMARY.—Manchester Royal Infirmary was open for inspectio the afternoon of Sept. 30th for the first time in its history large crowds took advantage of the occasion to visit X ray department and the operating theatres, whilst n ex-patients revisited the scenes of their recovery. N and officials acted as guides and showed the visitors work carried on in the infirmary.

Medical News.

ST. GEORGE'S HOSPITAL.—The annual dinner of the edical school was held on Saturday, Oct. 1st, at the Hyde ark Hotel, Sir Humphry Rolleston, consulting physician to ie hospital, and Regius Professor of Medicine, Cambridge, residing. The toast list was brief, but good speeches were rovided. The toast of "Prosperity to the School" was roposed by the Chairman, who naturally laid stress on the d association between his University and St. George's ospital, while he pleased his audience by a hearty recogni- on of the valuable part which games play in corporate aining and by special words of commendation for the student hlete. The toast was replied to by the Dean, Dr. Anthony eiling, who was able to report general progress as shown y a good entry, and a high percentage of success in examina- ons during the past year. He considered that it did not evolve upon him to give the details which usually came om the treasurer as to the financial position of the hospital, it he was able to state that, though there was ample scope the conduct of the hospital for the intervention of a illionaire, the pecuniary position had improved; and he rticularly desired his audience to understand that no ovement, either now or contemplated in the future, would ndanger the full accommodation of a first-class clinical edical school. The toast of the Chairman's health was oquently given by Dr. J. S. Collier, who in the course of umerating Sir Humphry Rolleston's many claims upon the miration and gratitude of St. George's Hospital, said that had been a pioneer in a remarkably useful piece of educa- onal work, when he instituted his series of informal lectures pathology, to which all-comers were admitted without es. Sir Humphry Rolleston briefly replied.

ST. MARY'S HOSPITAL.—The annual dinner of st and present students of St. Mary's Hospital Medical hool was held at the Connaught Rooms, London, on turday, Oct. 1st, when there was a large gathering of en and women students, and the invited guests included e Mayor of Paddington, Air-Marshal David Munro, and ce-Admiral Arthur Gaskell, R.N. Dr. Wilfred Harris, o presided, remarked that the hospital had always suffered m scarcity of beds, now to be relieved by the extension progress and the exploitation of the island site recently quired. Small wards for paying patients of moderate ans were urgently needed. They would be a good thing the medical school, they would provide a number of id appointments, and be of real service to the practitioners ng the hospital. His address was sprinkled with amusing ries of early hospital days and humorous maxims. Mr. R. Prideaux, chairman of the Hospital Board, who lied to the toast of "The Hospital and Medical School," d that a number of beds would be available in the course the present month, and final completion was expected April 30th next, when it was hoped their Majesties would en the building. Two new operating theatres, 46 additional ls (making 350 in all), would bring the hospital into line h other metropolitan teaching hospitals. The island , purchased at a cost of £65,000, to come into their session in November next, would safeguard for all time future of St. Mary's. Dr. C. M. Wilson, who as Dean the Medical School also replied, recounted the sorrows a dean in balancing a budget, and dwelt on the advantages the medical student of a school of moderate size, in which re was far more chance of securing a house appointment. gave some figures to show that scholarship and athletic wess are not antagonistic, and concluded with recom- nding St. Mary's as a school which had grafted on the uliarities of the smaller school the academic and university antages of the larger school. The toast of "The Chair- n" was proposed—from a wealth of local knowledge ich was warmly applauded—by Mr. D. C. L. Fitz- liams, and Dr. Harris brought the more formal proceedings he evening to a close with a neat little speech of gratitude l appreciation.

ST. BARTHOLOMEW'S HOSPITAL.—The Annual Old dents' Dinner of the hospital was held on Monday, . 3rd, in the Great Hall of the hospital, Dr. Morley tcher, the senior physician, presiding over a large mbly of St. Bartholomew's men and their guests. re were no speeches, but the chairman, in a short address, iewed recent events as they affected the medical college t the prosperity of the hospital. As proving the iquity of the college, he indicated that some 250 years the formation of a library for the use of the authorities l the students was recorded, while the annual dinner, ore recent institution, he considered to have sprung out he hospitable habit displayed by certain members of the who gave private dinners at the opening of the new ion. But there was evidence that in 1840 a regular ner was attended by the staff and students after an opening address had been given. Later, in 1862, an official notice appeared in the *Times* that an old students' dinner would be celebrated at the famous Albion Tavern, after which the function became annual; and he mentioned that the present senior consulting physician to the hospital, Sir William Church, now in his ninety-first year, had attended some 60 annual dinners. Dr. Morley Fletcher then made the announcement that the new surgical block, so long projected, was now in course of actual construction on the site of the old Christ's Hospital; it was planned, he said, to consist of five wards accommodating 250 patients. In speaking of the changes brought about by the past year, he referred to the deaths of Dr. Claye Shaw, for so many years lecturer in the college on psychological medicine, of Mr. Alban Doran, Prof. Strangeways, and Sir Arthur Shipley, once a student of the school. All, he added, would deeply regret Sir Frederick Andrewes's resignation of the post which he had held so long and with so much distinction. They now possessed, he said, three new professors at the school, W. E. Le Gros Clark, Hamilton Hartridge, and E. H. Kettle, respectively in anatomy, physiology, and pathology, and to these he extended the welcome of the meeting, while he congratulated one of their students, Dr. Burt White, on gaining the gold medal for obstetrics in the University of London. He concluded by saying never had better opportunities been offered to students by the college, though the financial burden was very serious.

MIDDLESEX HOSPITAL.—The annual dinner of past and present students of Middlesex Hospital was held at the Savoy Hotel, London, on Tuesday, Oct. 4th, Mr. Somerville Hastings presiding over a record assembly of Middlesex men and their guests. Mr. Hastings, in proposing the toast of "The School," gave a stirring account of the spirit in which the activities, both charitable and scientific, are being carried on while the destruction and reconstruction of the premises is proceeding. He claimed that the charge of the sick poor, the training of the nurses, and the pursuit of research were all proceeding as usual, while he said that new activities were being projected for their model institution that was rising in Marylebone. New departments were being made, and there would be many more laboratories, all of which would entail more officers, more men, and more money. The builders, he said, were now starting work on the first section of the new edifice, while a strictly anonymous donor had given £160,000 for the building of a nurses' home outside their island site, thus leaving room for additions to the hospital proper, so that, as well as increased ward space, it would be possible to provide some paying wards, a development of hospital activity most valuable to the public. Their model hospital, he assured his audience, would be a centre where the sick poor would remain its first charge, but where research could be carried on, and all local activities catered for. He relied for their success on the esprit de corps of the old friends and the new students. The toast was replied to by Mr. S. G. Asher, Chairman of the Board, Mr. Eric Pearce Gould, Dean of the School, and Mr. E. G. Muir, senior Broderip Scholar, representing the students. Mr. Asher, in reply, while admitting the anxieties of finance, pointed to the steady output of first-class work in research from the two great special departments of the hospital, which they owed to Sir John Bland-Sutton and Sir Samuel Courtauld, and again roused curiosity as to the generous donor by alluding to the magnificent donation for the erection of a nurses' home. Mr. Eric Pearce Gould related the remarkable successes of the students in the various schools, and wittily compared the rapid developments of the new hospital, with its foci here and metastases there, to the growth of a tumour. He had heard that lead had been used beneficially in association with certain of these growths, but the metal which Middlesex required was gold. Mr. Muir, with amusing directness, took the opportunity of the presence of influential members of the Board to point out a great many things which the students would like to have provided for them in the new buildings. He described the sort of Ritz accommodation which they would like, terminating with a plea for a swimming bath and mixed bathing. The toast of "The Guests" was proposed by Mr. Comyns Berkeley, to which Major Ian Hay Beith and Air Vice-Marshall D. Munro replied, each contributing to the gaiety of the evening.

UNIVERSITY OF BRISTOL: ASSOCIATION OF ALUMNI. The sixth annual dinner of the London branch of this Association will be held on Friday, Oct. 28th, at 7.30 for 7.45 P.M., at the Criterion Restaurant, Piccadilly-circus. Viscount Haldane will preside, and Prof. Francis Francis (Pro-Vice-Chancellor of the University) will be the guest of the evening. Members of the University and past members of its associated colleges may apply for tickets for themselves and their friends to Dr. Elizabeth Casson, Holloway Sanatorium, Virginia Water. A business meeting of the branch will be held, by invitation of Mr. C. A. Joll, at 64, Harley-street, W., on Wednesday, Oct. 19th, at 6.30 P.M.

UNIVERSITY OF MANCHESTER.—At recent examinations the following candidates were successful:—

DIPLOMA IN PUBLIC HEALTH.

Part I.—J. S. Smith.
Part II.—James Cumming, Barbara M. Knight, M. V. Menon, and S. P. Wilson.

HARVEIAN SOCIETY.—A clinical meeting of this society will be held at 4.30 P.M. on Thursday, Oct. 13th, at the Hospital for Epilepsy and Paralysis, Maida-vale, London, W.

MEDICO-LEGAL SOCIETY.—A meeting of this Society will be held at 11, Chandos-street, Cavendish-square, W. 1, on Thursday, Oct. 27th, at 8.30 P.M., when Sir William Willcox will give a presidential address.

ROYAL SANITARY INSTITUTE.—A sessional meeting is to be held on Friday, Oct. 28th, at 4.30 P.M., in the Council Chamber, Town Hall, Newcastle-upon-Tyne, when discussions will take place on (1) the Influence of Overcrowding upon Tuberculosis, with special reference to the New Housing Schemes; (2) the New Factories Bill; and (3) the Smoke Problem on Tyneside—How is it to be Tackled? Dr. Charles Porter will take the chair.

CHILD-STUDY SOCIETY.—A series of lectures and discussions is to be held by this Society at the Royal Sanitary Institute, 90, Buckingham Palace-road, on Thursdays, at 6 P.M. On Oct. 13th Dr. E. A. Hamilton-Pearson will speak on the Unadopted Child. Further particulars are obtainable from the hon. secretary of the society at the Institute.

THE PRIX HOLLANDAIS IN ANTHROPOLOGY.—At the closing meeting of the Congress of the International Institute of Anthropology, in Amsterdam, on Sept. 24th, it was announced that the Prix Hollandais, worth over £600, for the best work in physical anthropology or pre-history, had been awarded to Miss Garrod, daughter of Sir Archibald Garrod, Regius Professor of Medicine in the University of Oxford, for her paper on the new Gibraltar skull.

CALEDONIAN MEDICAL SOCIETY.—The annual meeting and dinner of this society will be held on Friday, Oct. 14th, under the presidency of Dr. Angus MacGillivray, chief of the Dundee Highland Society. The meeting will be held in the University College, Dundee, and the dinner in Kidd's Rooms, South Lindsay, West Dundee. On the Saturday the members will pay a visit to St. Andrews on the invitation of the University Court.

BELGRAVE HOSPITAL FOR CHILDREN.—A series of clinical meetings will be conducted by members of the staff of this hospital, whose address is 1, Clapham-road, London, S.W. 9. The first will be on Oct. 12th (Dr. Edmund Cautley), the second on Nov. 9th (Mr. Sidney Boyd), and the third on Dec. 14th (Dr. M. Sydney Thomson). Medical practitioners are invited. There will be tea at 4 P.M. and the meetings will be at 4.30.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Tuesday, Oct. 11th, at 4 P.M., Mr. Mayou will give a special demonstration for the Fellowship at the Central London Ophthalmic Hospital, Judd-street, London, W.C. This will be free to members of the medical profession. A clinical course continuing for two more weeks is in progress at the Central London Throat, Nose and Ear Hospital. Almost the whole day can be spent at the hospital. On four successive Wednesdays, at 5.15 P.M., beginning on Oct. 12th, Dr. C. B. Heald will give a series of lecture demonstrations intended for general practitioners who wish to familiarise themselves with recent advances in treatment by electrical methods. An all-day course in Diseases of Children will be given at the Paddington Green Children's Hospital, and the Victoria Hospital for Children, from Oct. 17th to 29th. Also, beginning on Oct. 17th, there will be a two weeks' course in gynæcology at the Chelsea Hospital for Women. During October and November a comprehensive course will be held at the National Hospital, Queen-square, the subjects including general neurology, the pathology of the nervous system, methods of examination and anatomy, and the physiology of the nervous system. Any part of the course may be taken separately. A series of demonstrations on the diagnosis and treatment of diseases of eye will be given at the Royal Eye Hospital between Oct. 24th and Nov. 5th. On Monday, Oct. 17th, at 5 P.M., at the rooms of the Medical Society of London, 11, Chandos-street, W., Sir Humphry Rolleston will give the first of a series of lectures entitled Practical Hints on Medicine, Surgery, and the Allied Specialties. His subject will be the Diagnosis and Treatment of some Endocrine Disorders. Copies of all syllabuses are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, W. 1. The programmes will be sent regularly to those who express a wish to receive them.

THE POPULATION CONFERENCE.—A lecture on th recent conference at Geneva will be given to the Societ for Constructive Birth Control and Racial Progress b Prof. Julian Huxley, at the Essex Hall, Essex-street, Stran on Thursday, Oct. 20th, at 8 P.M.

BIOCHEMICAL SOCIETY.—A meeting of this Societ will be held at the Biochemical Laboratory, Cambridg to-morrow, Saturday, Oct. 8th, at 3 P.M. Among the con munications to be read is one by G. S. Haynes and C. G. Wolf on the Interferometer Method for the Diagnosis Pregnancy and Malignant Growths.

THE SEMON LECTURE.—Mr. Lionel Colledge wi deliver the Semon Lecture in the Barnes Hall of the Roy Society of Medicine, 1, Wimpole-street, W., on Thursda Nov. 3rd, at 5 P.M. His subject will be the Present Positi of Laryngectomy for Cancer of the Larynx, and Mr. Haro Barwell will take the chair.

JEWISH HEALTH PROBLEMS.—Dr. Julius Brutzku ex-minister of the Lithuanian Government, will lectu in German on Jewish Health Problems in Eastern Euro at the Jews' College, Guilford-street, London, W.C., Sunday, Oct. 9th, at 4.30 P.M.

INSTITUTION OF HEATING AND VENTILATI ENGINEERS.—A meeting will be held at 12, Russell-squa London, W.C., on Tuesday, Oct. 11th, at 6.45 P.M., wh Dr. J. S. Owens will speak on Atmospheric Pollution.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—T annual general meeting will be held on Friday, Oct. 14 at 8.45 P.M., at the Miller General Hospital, Greenwi S.E. Clinical cases will be shown by Mr. C. A. J Dr. H. Nockolds, and Mr. P. B. Roth. Mr. H. P. Winsbu White will demonstrate a series of nephrectomy specime

BRITISH INSTITUTE OF PHILOSOPHICAL STUDIES. The first of the evening meetings for the session 1927- will be held at the Royal Society of Arts, 18, John-stre Adelphi, W.C., on Tuesday, Oct. 11th, at 8.15 P.M., wh Dr. John Rickman and Dr. H. G. Baynes will lecture the Standpoints of Freud and Jung. A limited num of seats are reserved for members of the public who c to apply for tickets.

CHORLTON.—On Sept. 28th, at Buxton, the wife of Dr. J. S. Chorlton, of a daughter.

JEROME.—On Sept. 25th, at Sandhurst, Sutton Coldfield, the wife of John S. Jerome, *M.C.*, B.M., B.Ch. Oxf., of twin daughters.

ROWLEY.—On Oct. 1st, at a nursing home, Clifton, the wife of Dr. A. T. F. Rowley, Wrington, Somerset, of a daughter.

TELFER.—On Sept. 27th, the wife of Dr. A. C. D. Telfer, Howard-road, Walthamstow, London, E., of a daughter.

MARRIAGES.

WALKER—NIALL.—On Sept. 5th, at St. Michael's Church, Chatham, by the Rev. Father Ryan, Captain Cyril V. Walker, Army Dental Corps, son of the late Dr. C. E. Walker, of Hurworth, and Mrs. Walker, of Woodlands-terrace, Darlington, to Norah M. A. Niall, M.R.C.S. Eng., L.R.C.P. Lond., eldest daughter of Dr. and Mrs. W. G. Niall, Kinkora, New-road, Chatham.

DEATHS.

SANGSTER.—On Sept. 30th, Charles Sangster, M.R.C.S., L.R.C.P., late of Lambeth, aged 81.

*N.B.—A fee of 7*s.* 6*d.* is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Notes, Comments, and Abstracts.

PLAN FOR AN INTERNATIONAL HOSPITAL CONGRESS.

AT the invitation of the American Hospital Association and of the League of Red Cross Societies representatives from 11 countries met on Sept. 19th in Paris, at the headquarters of the League, to discuss the advisability of calling an International Hospital Congress. The representatives of Great Britain were Mr. J. Courtney Buchanan, hon. secretary of the British Hospitals Association; Lieut.-Colonel Clement Cobbold, of the Gordon Hospital for Rectal Diseases, London; Mr. W. H. Harper, house governor of the Wolverhampton and Staffordshire Hospital; and Captain J. E. Stone, hon. secretary of the Incorporated Association of Hospital Officers. The preparatory work for the meeting had been carried out by Dr. E. H. Lewinski-Corwin, director of the Hospital Information and Service Bureau of the United Hospitals Fund of New York, and the delegates were welcomed by Dr. Joseph C. Doane, medical director of the Philadelphia General Hospital and president of the American Hospital Association. At the unanimous invitation of those present Dr. René Sand, technical counsellor to the League of Red Cross Societies, took the chair.

The delegates were unanimously in favour of holding an international hospital congress, and discussed the best time and place for it. Invitations were received from Groningen, Prague, and New York, and it was eventually agreed to accept the American invitation for the first congress. Several of those present expressed the opinion that it was impossible to organise a congress in less than two years, so the date was provisionally fixed for June, 1929. An international executive committee, consisting of two delegates from each participating country, is to be appointed for the general preparation of the congress, and Dr. Lewinski-Corwin will act as its general secretary. Those present were invited to organise national committees in their respective countries with a view to forwarding the aims of the congress.

It was decided that the problems to be discussed should be limited as far as possible to the following: (*a*) the founding of national hospital associations, and of an international hospital association; (*b*) the respective fields of public and private hospital work; (*c*) the hospital as a centre for cure and prevention of disease, medical education, and research; (*d*) the training of hospital executives, nurses, and auxiliary personnel; and (*e*) the economic problems of hospital administration. One session will be devoted to the discussion of such special problems as the care of the mentally ill and the comparability of hospital statistics. An international exhibition is to be arranged at the time of the congress, and visits will be paid to the hospitals of New York, Philadelphia, Baltimore, and Washington. Nurses were represented at the meeting by Miss Reimann, secretary to the International Council of Nurses, who expressed a wish that the date of the congress and that of the International Nurses' Congress, which is to meet in Montreal in 1929, might be so arranged as to facilitate attendance at both.

"H.M. BUG-CATCHER."

To the Editor of THE LANCET.

SIR,—In your issue of July 16th, p. 156, you express some surprise that a man holding a Royal Warrant of "Bug Catcher to His Majesty," should be mentioned in Boyle's Court Guide of 1837. Whether the Royal Warrant was continued in the reign of Queen Victoria I do not know for certain, but I do know that the person referred to, whose identification is easy, or his successor in an old-established firm of upholsterers and furniture cleaners, located in Great Marylebone-street, near Marylebone-lane, styled himself on a board or plate displayed in his shop window as "Bug Exterminator to the Royal Family." This was always to be seen in my younger days and perhaps is there still.

The same expert in hunting small game to whom you refer contributed an interesting article on the subject of *Cimex lectularius* to Mayhew's "London Labour and the London Poor," Vol. III. In this he not only recounts some of his professional exploits, including a visit to the palace to relieve Princess Charlotte of a parasite that had tormented her, but gives a very good account of the natural history of the insect, with useful details not readily to be obtained elsewhere. He states that it is supposed that bugs were first introduced into England after the Great Fire of London, in timber that was imported for the rebuilding of the city. His ancestor started his warfare against the pest soon after.—I am, Sir, yours faithfully,

F. LUCAS BENHAM, M.D., M.R.C.P.

Semaphore, South Australia, August 22nd, 1927.

EFFECT OF ULTRA-VIOLET LIGHT ON PLANTS.

IT is a common statement that ultra-violet light is evidently not needed for the healthy growth of plant because every variety of plant can easily be cultivate behind glass which is impervious to ultra-violet ligh E. M. Delf [1] points out that this belief is incorrect; differer kinds of glass differ in the degree to which they transm ultra-violet light and all are not impervious to it; als many tropical and subtropical plants, grown in Englan under glass and with every precaution as to temperatu and moisture, refuse to thrive as they would in their ow country. Such experimental work as has previously bee done has rather gone to show that ultra-violet light actually harmful or even fatal to plants, and Delf mentio that previous workers found that a single long exposu of 2½ hours, or repeated shorter ones of even as little 5 minutes a day, had a fatal or a severely stunting effe upon them. In her own experiments, she sought to ascerta whether in any circumstances dosage with ultra-violet lig can be of benefit to greenhouse plants. She used a Hewitt quartz mercury-vapour arc and gave exposures of 30 secon or longer. All doses which she used, from 10 minutes dov to 1 minute, had a harmful effect, but when she us doses as small as 30 seconds on a number of successive da a beneficial action was observed after a certain latent perio Though no more than suggestive this investigation affor an interesting analogy to work at a certain stage in t history of the irradiation of animals. Certain earlier worke exposed rats to ultra-violet light for lengthy periods an in consequence, reported that the effect of the rays is whol harmful. They entirely missed the extremely importa biological action of small doses of the rays.

It would be interesting to know whether glass whi transmits ultra-violet rays freely can be usefully employ to increase the growth of fruit and vegetables in greenhous It has been stated that an experiment with tomatoes show that improvement was obtained with this kind of glass.

ULTRA-VIOLET LAMPS.

Messrs. Watson and Sons (Electro-Medical), Ltd., ha recently issued an abridged catalogue giving illustratic of a selection of the various sources of ultra-violet radiati useful for therapeutic work. Their "Sunic" and "Kin way" models appear to be of simple and workable desi and are adapted for use with the mercury-vapour type lamp; the former model is also available for use with t open tungsten arc. It is worth noticing that protecti goggles for the eyes of operators are now made so that th reflect a large percentage of the heat received from open lamps; this is done by plating the glass with a transpare film of gold.

A BADLY-FITTING TRUSS.

To the Editor of THE LANCET.

SIR,—I have frequently suffered sickening and exhaust pain for the past seven years owing to the repeated failu of the many trusses which I have patiently worn for mon at a time for my double scrotal hernia. I feel that I ha sufficiently graduated in the school of suffering to ventil my experiences, which are briefly the failure of the applian provided to effect their object, caused apparently by t lack of coöperation between the surgeon and the mechanici the latter of whom is often hardly more than a salesman

I am told that there is no hospital for hernia; can t possibly be true in London? In all my inquiries I ha never heard of a surgeon specialist in the mechanics of truss, though, of course, I have heard of many surgeons w operate for hernia—an operation for which I am far old. The general practitioner seems to know little or noth of the mechanics of the truss.

When I go to the dentist he fits my denture, or rat gets it fitted, until I am comfortable. Is it too much to the surgeon to do the same with the truss which he ord for me? I am, Sir, yours faithfully,

Sept. 29th, 1927. SENEX

Ingleby Lectures

ON

PLACE-IN-FAMILY AS A FACTOR IN DISEASE.

Delivered at the University of Birmingham

BY G. F. STILL, M.D. CAMB., LL.D. EDIN., F.R.C.P. LOND.,

PROFESSOR OF DISEASES OF CHILDREN, KING'S COLLEGE HOSPITAL; CONSULTING PHYSICIAN, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

LECTURE I.

THE progress of medical science in recent years has tended more and more to reduce the causation of disease to terms of bacteriology and biochemistry—and this with immense gain to mankind; but there are other factors which determine morbid conditions whether congenital or acquired, factors which being more shadowy and difficult to define lend themselves less readily to scientific study by the precise and accurate methods of the laboratory. Such an one is the influence, if any, of place-in-family, and the questions I have set myself to consider in these lectures are the existence and the nature of any causal relation between place-in-family and those abnormalities of function or formation which are of antenatal origin. In this definition I do not mean to include only those affections or conditions which are manifest at birth, such as congenital malformations, but also some which, although they may not make their first appearance until weeks, months, or even years after birth, seem nevertheless to have as their underlying cause an inborn vice, a sort of pathological predestination, which dates back to some antenatal period, for example, hypertrophy of the pylorus and probably some cases of epilepsy.

In this first lecture I shall consider (1) what evidence there is for the general proposition that place-in-family is a factor in the causation of disease; (2) what evidence there is of such influence in particular affections belonging to the group just defined. Prof. Karl Pearson [1] in 1914 published a lecture On the Handicapping of the First-born, embodying statistics collected by himself and others with regard to various affections, mainly as indirect support for his earlier contention that the elder-born were specially liable to tuberculosis, insanity, and criminality. His point of view was chiefly the sociological and eugenic. The observations which will be considered in these lectures were made quite independently and indeed were almost completed before I was aware of Prof. Karl Pearson's interesting papers, and they were made from a different standpoint.

In seeking for light upon the obscurity of certain conditions of antenatal origin it seemed to me that if the impression gained from clinical experience as to influence of place-in-family were confirmed, this might be a step in the elucidation of their pathogenesis. I have therefore been collecting for several years statistics on this point from my own personal observations, several of my hospital colleagues have kindly allowed me to make use of their cases also, and I am specially indebted to my revered and lamented friend, Dr. John Thomson, of Edinburgh, who generously furnished me with statistics which he had himself collected on this particular point but had not published.

DEFINITION OF PLACE-IN-FAMILY.

If the subject is to be approached with a view to pathology or pathogeny—and, indeed, from any point of view—it seems to me essential that the term place-in-family should mean place in order of pregnancies, not merely place amongst live-born; in other words, the order must include miscarriages and stillbirths. A first pregnancy—whether it results in a miscarriage, a stillbirth, or a live child—involves physiological and anatomical changes in the mother, some of which remain for years, if not permanently, so that a live-born child, the result of a second pregnancy following a miscarriage or a stillbirth, is not, even so far as the gross antenatal environment is concerned, the equivalent of a first-born; nor is there any reason to suppose that it is, so far as those subtler and more obscure influences are concerned which determine the course of development. If these influences have any special tendency to perversion in the first pregnancy they may be expected to show it at least as much in an aborted embryo or fœtus or a stillborn child (in each of which, be it noted, abnormalities of development have been observed) as in a live-born; and if this tendency to perversion is less in subsequent pregnancies then it is fallacious, for the purpose of this inquiry, to count as first-born the child which happens to be the first live-born when there may have been one or even several previous pregnancies ending in miscarriage or stillbirth. Most of the statistics which have been published in connexion with this subject ignore this point altogether, and are therefore of no value for my present purpose.

The facts recorded here as to the order of pregnancies were obtained almost invariably from the parents, nearly always from the mother, and nearly all the children to whom my statistics refer were under the age of 12 years. I had not gone far in this investigation before I learned that after a mother has had some live-born children she soon becomes forgetful of her past reproductive history, and the older her children the more likely she is to omit or misplace miscarriages or stillbirths. A history taken from an adult with regard to his mother's pregnancies seems to me to be almost worthless; many, probably most, adults have no knowledge whatever of the number or order of any miscarriages or stillbirths which the mother may have had, and consequently the place-in-family of adults is very liable to be stated inaccurately. For this reason the influence of place-in-family is best investigated with regard to children, and provided completion of family does not affect the problem to any appreciable extent—a point to which I shall refer later—statistics obtained thus will be far more reliable than any with reference to adults.

In certain respects primogeniture is well recognised as involving special risks; the mechanical difficulties of a first labour are the cause of various affections from direct trauma, from asphyxia, from hæmorrhage, and so forth; the present inquiry is not concerned with these but only with the influence of primogeniture in respect of conditions which are of antenatal origin as already defined.

INCIDENCE AND LIABILITY.

It must be pointed out in the first place that incidence and liability are not interchangeable terms. Some confusion has arisen from lack of clearness on this point. For instance, to show that 40 per cent. of cases of congenital deformities are first-born, whereas only 20 per cent. are second-born, is not necessarily equivalent to showing that the first-born are twice as liable to these affections as the second-born; it is even possible that the very reverse might be true. The incidence of disease in relation to place-in-family tells us nothing about liability to disease in this respect, unless the incidence can be correlated with the number of pregnancies belonging to each place-in-family as found in the whole population, or, if this is impracticable—as it is—with the most reliable average for these numbers which can be obtained.

It sounds plausible enough, as an argument in favour of the special liability of the first-born, to state that 40 per cent. of the cases of any particular

[1] Karl Pearson: On the Handicapping of the First-Born. London: Dulau and Co. 1914. Vide also the Supposed Inferiority of First- and Second-Born Members of Families, Statistical Fallacies. By T. B. Macaulay, F.I.A., F.A.S., Montreal.

disease occur in the first-born; a form of statement which George Eliot scathingly described as "a statistical amount without a standard of comparison but with a note of exclamation at the end." The fallacy can be appreciated if one supposes a country in which the number of children in any family was two; it is obvious that the occurrence of 50 per cent. of the cases of any disease in the first-born would not in the slightest degree indicate any special liability of the first-born. Moreover, supposing that a population consisted of 200 first-born, 120 second-born, and 80 third-born, and that of the persons affected by a particular disease in that population 90 were first-born, 60 second-born, and 50 third-born, so that of the 200 persons affected by the disease 45 per cent. were first-born, 30 per cent. second-born, and 25 per cent. third-born; these figures of incidence so far from proving that the first-born are specially liable, and that the second-born are more than liable than the third-born, prove exactly the reverse, for when the figures are compared with those of the total population it is seen that of the first-born only 45 per cent. were affected, while of the second-born 50 per cent., and of the third-born 60 per cent. were affected.

FIG. 1.—*Consecutive Private Cases (1000).*

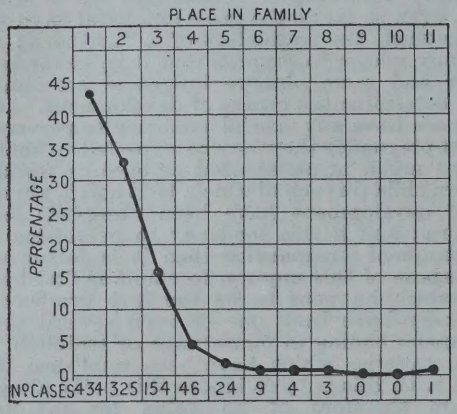

FIG. 2.—*Consecutive Private Cases, J. Thomson (1000).*

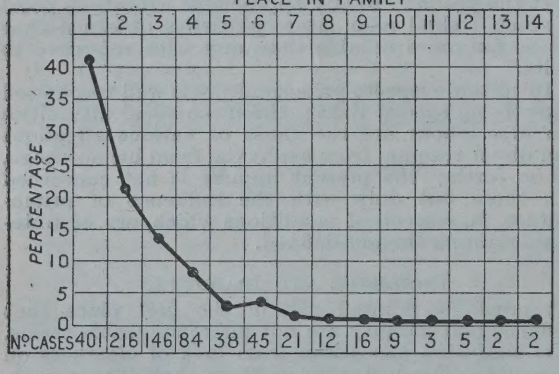


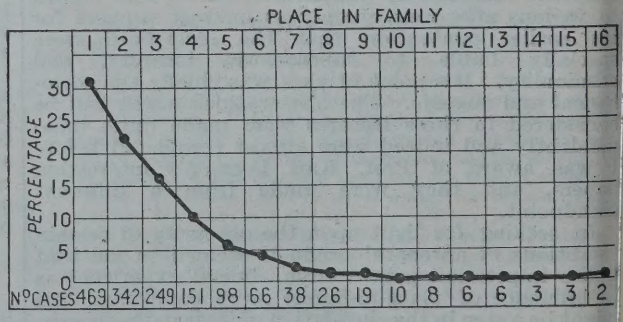
The method of comparison adopted in this imaginary case is the ideal way of ascertaining whether any particular place-in-family has any special liability to a particular disease, but it is obviously impracticable; there is no means of ascertaining the number of persons in the whole population belonging to each place-in-family, and it is also practically impossible to know the total number of cases of any particular disease occurring in the population with reference to place-in-family. Another mode of comparison is, however, available. The proportion of each place-in-family in the general population may be estimated from a sufficiently representative portion of it, and with this may be compared the proportion of each place-in-family in a number of cases of any particular disease. Such a method is less accurate than the former; it is difficult to be sure that any partial figures are representative of the whole population, and in any series of cases of any particular disease the accuracy of any generalisation as to the proportion of each place-in-family will depend upon the number of cases collected, even if the fallacy of selective influences is eliminated.

STANDARD PROPORTIONS OF PLACE-IN-FAMILY.

It is necessary, however, if we are to deduce liability from incidence, that we should have some reasonably reliable standard of comparison. Herein lies one of the chief difficulties of this inquiry. Miscarriages and stillbirths are not recorded in official registrations; even in hospital records there is often no note of miscarriages or stillbirths, or at best, a note with no reference to their place-in-family unless the patient happens to be suffering from some disease in which the point is thought to be of importance. The readiest source to hand seemed to be one's own private case-notes, so I took 1000 consecutive cases without regard to the reason of their being brought for medical examination. The result is shown in Fig. 1. Dr. John Thomson took the same number from his private records and obtained a result (Fig. 2) which corresponds very closely with mine. The striking feature of these curves is not merely the predominance of the first-born which might be expected, but the degree of this predominance. This is so marked as to suggest that there may be some fallacy; a comparison with other figures proves that this is so.

For another series of cases (Fig. 3) from private case-books, those of an obstetrician, I am indebted to Dr. Herbert Spencer. This comprises 1500 pregnancies, including, as do all the figures given in these lectures unless otherwise stated, miscarriages and stillbirths. The proportion of first-born is seen to be considerably lower than that obtained in the two previous series, and this is probably due to the elimination of certain fallacies which I shall mention later; it is, in fact, a nearer approximation to truth, though still probably exaggerating the normal preponderance of the first-born. Evidence of this is, I think, available; official birth registrations in Scotland showed a proportion of first-born 21·6 per cent. As already pointed out, these statistics from birth registration are inadmissible for determining the proportion belonging to each place-in-family inasmuch as they do not include miscarriages or stillbirths, but so far as my present point is concerned—viz., the proportion of the first-born—they have some small value, for it is obvious that if there is any live-born family the inclusion of previous miscarriages and stillbirths cannot do otherwise than reduce the proportion of first-born live children, so that any error in the proportion of first-born in such statistics must be an error of excess.

FIG. 3.—*Pregnancies (1500 Cases).*



The exact amount of this excess it is difficult to estimate, but in a series of 800 live-born children it was found that inclusion of miscarriages or stillbirths made a reduction of 7 per cent. in the proportion of the first-born. Other similar figures might be quoted all subject to the same fallacy (at least there is no statement to the contrary) that they do not include miscarriages or stillbirths. This omission limits this value for my purpose to a vague and unreliable indication of the proportion of the first-born. I shall, therefore, only mention some of the results obtained with reference to this particular place-in-family. Dr. Matthews Duncan,[2] from figures supplied by Dr. A. Mitchell, found the percentage of first-born to be 22·8; Karl Pearson, from much more recent figures (1911) also from Scotland, found that the percentage was 21·6, and in another series from the poorest Glasgow population 22·5. It would seem, therefore, that 41·75 per cent.—the figure obtained from statistics of 2000 private patients, by combining my figures with Dr. Thomson's—is much too high. The reasons of this, I think, are not far to seek. In the first place, these records include many children brought because they were suffering from some condition in which, as I shall show, primogeniture is apparently a factor, and the proportion of these will therefore be much higher than in any statistics of general population; secondly, these records include a large number of children brought for the very reason that they were first children, the mother's inexperience has prompted her to seek medical advice for some difficulty of infant feeding or some slight ailment which in the sixth or seventh, or even the second or third, receives less anxious attention; and lastly, a fallacy probably slighter in degree, these statistics deal chiefly with families of the middle or wealthier classes in which the size of family is on the average less than amongst the poorer so that the proportion of first-born, and indeed of other early born children also, is increased. This last fallacy applies no doubt also to the curve which I have taken from an obstetrician's private cases, and here also it is likely that a first pregnancy is more liable to be thought to require specialist's care than the later ones.

All these fallacies can, I think, be eliminated to a very large extent, if not entirely, by taking figures of some acute disease of what I would call "neutral" character, so far as place-in-family is concerned, a disease in which, owing to its acuteness or its alarming symptoms, medical advice is equally likely to be sought, whether it be the first child, or the only, or the late-born of a large family; and if these figures are derived from hospital practice where financial considerations have less influence, the elimination of fallacy will be still more complete. By "neutral" I mean diseases in which there seems to be no reason to expect that place-in-family would be a determining factor; an assumption, I admit, but one which seems to be justifiable in the case at any rate of such diseases as the two which I shall consider as typical of this category—namely, broncho-pneumonia and croupous pneumonia. In Figs. 4 and 5 it will be seen that in both these affections the percentage of first-born is just under 20 per cent., and that this curve slopes gradually and almost evenly downwards to the fourth or fifth pregnancy, after which there is a more sudden fall. The proportion of first-born is, in accordance with what might be expected—namely, slightly lower than that given by birth registration statistics which, as already shown, err on the side of excess owing to the omission of miscarriages and stillbirths.

As a working hypothesis, therefore, I think it is safe to take these curves of acute disease of presumably neutral character as a standard of comparison for the various affections which are now to be considered, and by combining these two series of statistics, so as to obtain larger figures (900) any error will be reduced and a curve obtained which I shall call the standard curve (Fig. 6), admitting that it is only a working hypothesis. If this standard curve represents approximately the place-in-family distribution of the general population, one would expect that any disease in which no special liability attaches to place-in-family would conform more or less closely to this curve. This is shown by the charts of two diseases selected at random from those in which there would seem to be no special probability of antenatal influence from place-in-family—viz., tuberculosis and digestive disorders (Figs. 7 and 8). In both there is a gradual slope downwards from the first place, which in both approximates, as it does in the standard curve, to 20 per cent.

Having now obtained what I believe to be a sufficiently reliable standard of comparison, I pass on to the consideration of certain affections which, so far as my evidence goes, seem to indicate some special influence of place-in-family.

FIG. 4.—*Broncho-pneumonia (400 Cases).*

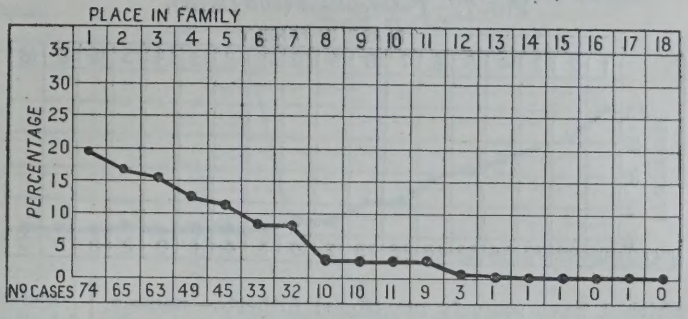


FIG. 5.—*Lobar Pneumonia (500 Cases).*

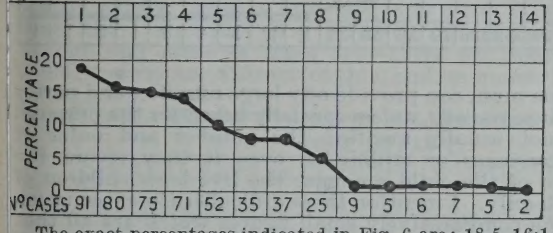

FIG. 6.—*Standard Curve.*

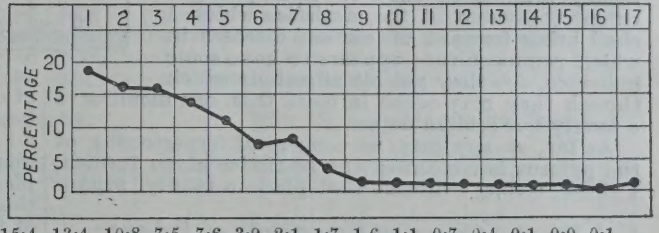


The exact percentages indicated in Fig. 6 are: 18·5, 16·1, 15·4, 13·4, 10·8, 7·5, 7·6, 3·9, 2·1, 1·7, 1·6, 1·1, 0·7, 0·4, 0·1, 0·0, 0·1.

CONGENITAL HYPERTROPHY OF THE PYLORUS.

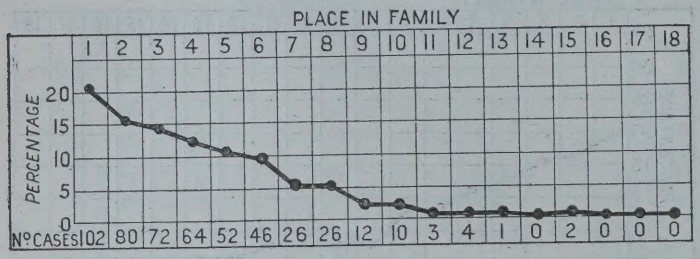
This may be mentioned first, for there is, perhaps, no affection which shows more convincingly the influence of place-in-family. I have been able to collect from my own observation 300 cases, and in order to obtain a nearer approximation to accuracy by larger figures I have combined with these 100 cases from Dr. Thomson's records (Fig. 9). The proportion of first-born is remarkable; it is 48·5 per cent., a proportion so far beyond any found in the charts shown above, and particularly so far in excess of the standard that the element of chance can

[2] M. Duncan: Fecundity, Fertility, and Sterility, 1866.

hardly be considered, and one is driven to assume some causal influence of primogeniture.

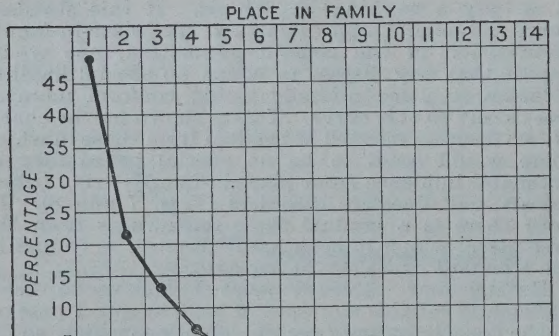
The steepness of the fall from first-born to second-born and later is a striking feature of this curve and not parallelled, so far as I know, by any other condition. The more importance may be attached to this curve because it is almost free from one fallacy which I have scarcely mentioned hitherto—namely, incompleteness of family. Some affections, especially the commoner ones, such as enlargement of tonsils or appendicitis, may affect the first-born, but they often affect also one or more of the later children of the same family, so that unless statistics are taken from completed families the results might be misleading; congenital hypertrophy of the pylorus, on the contrary, very rarely occurs twice in the same family (according to my own observations this happens only in about 1–2 per cent. of the families showing this affection), so that the proportion of first-born would be altered very little if statistics could be taken from completed families only. Probably this fallacy diminishes only to a very slight extent the value of the statistics which I shall bring forward of certain diseases in which primogeniture appears to have some influence, for they are all affections which though they may occur in more than one member of a family but seldom do so.

FIG. 7.—*Tuberculosis (500 Cases).*



As far, at any rate, as congenital hypertrophy of the pylorus is concerned the statistics given furnish, I think, strong evidence that place-in-family, primogeniture to wit, is an ætiological factor; and further, if we can regard this as established for one disease then the general proposition that place-in-family can be a causal factor in disease is established, and it is probable that we shall find it a factor in other affections.

FIG. 9.—*Congenital Hypertrophy of Pylorus (400 Cases).*

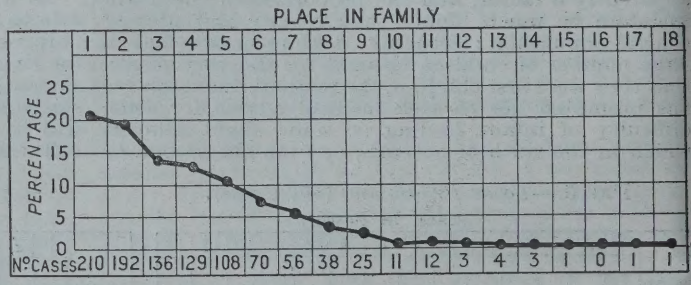


CONGENITAL HEART DISEASE AND OTHER MALFORMATIONS.

In association with congenital hypertrophy of the pylorus, various congenital anomalies have been observed. Dr. Thomson in 100 cases observed achondroplasia once (second child), congenital heart disease once (sixth child), and amongst my 300 cases there were three cases of congenital heart disease (second, fifth, and fifth child respectively), one of Mongolism having also congenital talipes varus (first child), one of congenital hydronephrosis (first child), one of severe unilateral congenital talipes (first child), and one of webbed toes (fourth child). If these are more than chance associations it seems a reasonable inference that there may be some common factor in causation, and that amongst the possible factors is to be reckoned place-in-family. Of the few cases mentioned, however, only three—the Mongolism, the hydronephrosis, and the congenital unilateral talipes—were in first pregnancies; two of the cases of congenital heart disease were in fifth pregnancies, and one in sixth, so that the association was noted not only in first pregnancies but also in late pregnancies, a fact which, as I shall show later, may have some significance.

This brings me to the consideration of congenital deformities. It is not easy to produce large statistics of these, partly because they are not so frequent that the experience of a few observers, and still less of one man, can provide any large number, and partly because records, unless specially taken for the purpose, do not usually mention the number and order of miscarriages or stillbirths, even if they record the place of the child amongst the live-born children of the family. I mention these difficulties in extenuation of the comparatively small figures which are all that I can bring forward in illustration of some of my points; and no one realises more fully than I do how easy it is to arrive at incorrect conclusions by arguing from insufficient statistics.

FIG. 8.—*Digestive Disorders (1000 Cases).*

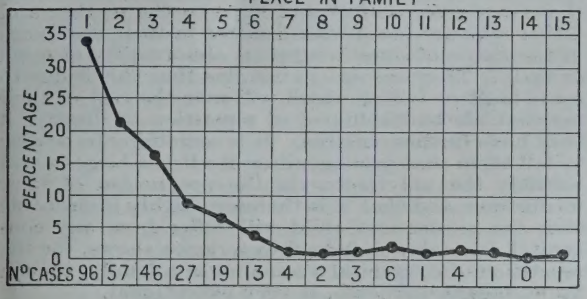


With this parenthesis of apology I pass to the place-in-family incidence of congenital heart disease as shown in statistics of 250 cases (Fig. 10). The proportion of first-born is far above that of the standard chart (Fig. 6), although not so high as in congenital hypertrophy of the pylorus. It would seem, therefore, that there is some special liability of the first-born to this particular form of congenital abnormality.

More marked evidence of special liability of the first-born to congenital abnormalities in general is afforded by figures grouping together malformations of all sorts. In Fig. 11 are collected 160 cases of hare-lip and cleft palate (43), congenital hydrocephalus (33), hypospadias (5), congenital obliteration of œsophagus or bowel (5), of bile-ducts (5), spina bifida, congenital cataract, coloboma iridis, congenital deaf-mutism, absence or redundancy of parts of limbs, and other malformations. I have not included congenital malformations of the heart in this series as they have already been considered. It will be seen that 41·8 per cent. were first-born, a proportion which seems to corroborate the evidence already given of some special liability in the first pregnancy to anomalies of development. I must point out that these figures refer only to congenital abnormalities which were recognisable clinically. As every morbid anatomist knows, autopsy sometimes reveals abnor-

malities which were not suspected during life—for instance, absence of one kidney, or a diverticulum from some part of the intestine, or some abnormal arrangement of blood-vessels—so that in the absence of universal post-mortem examination it is impossible to determine place-in-family incidence of congenital abnormalities with any such accuracy as is possible,

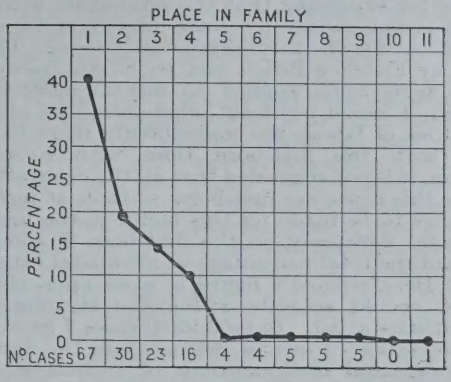
FIG. 10.—*Congenital Heart Disease (280 Cases).*



for instance, in such a condition as congenital hypertrophy of the pylorus. Nevertheless, the striking liability of the first-born to those abnormalities which are recognisable clinically makes it reasonable to suppose that if it were practicable to include in the statistics also those which can only be detected by autopsy the result would not be materially altered.

I am not considering in these lectures any special liability which may attach to place-in-family from intranatal causes, whether it be from the special difficulties of labour which attach to primiparity or the lesser dangers which are involved in the precipitate labour which is more likely to occur in the multipara. Nevertheless, I shall mention here the congenital spastic palsies because, although it is often assumed that they are due to difficulty of labour—as undoubtedly some of them are—there are many in which there is no evidence of this, and, moreover, the usually assumed that in such cases both affections are due to some damage of the cerebral cortex, directly or indirectly from meningeal hæmorrhage or asphyxia during labour. It is proved, however, by autopsies that in some cases the cerebral condition is one of much earlier developmental origin; certainly

FIG. 11.—*Congenital Abnormalities (160 Cases).*



the association does not prove that either or both are the result of difficult parturition. This brings me to the question how far mental deficiency apart from congenital cerebral palsies is related to place-in-family. The answer is not so simple as might be supposed if by the influence of place-in-family is meant, as in these lectures, the antenatal and developmental influence of place-in-family. The difficulty of eliminating intranatal causes such as asphyxia and traumatism is great. No one doubts that a certain proportion—probably a small one—of cases of mental deficiency are due to these causes which, it is agreed, will be operative chiefly in the first-born; but the uncertainty in particular cases is so great that I have been unable to separate them, so that my figures are open to the criticism that they probably include a

FIG. 12.—*Mental Deficiency; not Mongols (450 Cases).*

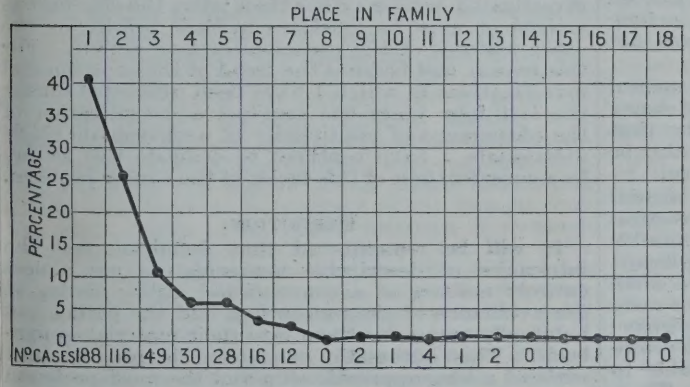


FIG. 13.—*Epilepsy (120 Cases).*

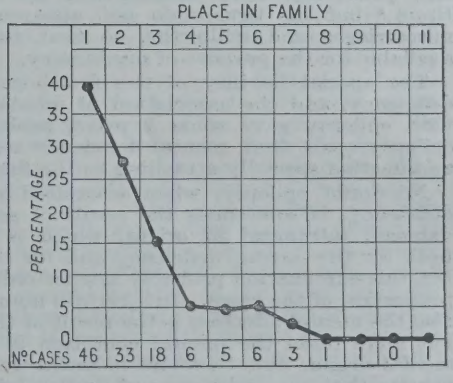

history of prematurity in some is opposed to it, and in some the labour has been particularly easy and occasionally congenital developmental anomalies have been associated with the spastic palsy, strongly suggesting that this also was due to some developmental imperfection of antenatal origin. Of 80 cases under my observation 39 were first-born, and in some of these first-born cases it was specially noted that the labour was easy and there was no asphyxia. It may be correct to regard the special incidence of spastic palsies on the first-born as due chiefly to the special difficulties of a first labour, but I would suggest that it may also be related in larger measure than has been recognised to a special liability of the first pregnancy to developmental anomalies.

MENTAL DEFICIENCY, EXCLUDING MONGOLISM.

With the spastic palsies there is often associated mental deficiency of greater or less degree, and it is certain number of cases in which primogeniture was causal only on account of the difficulty of labour.

Admitting that the exclusion of such cases, if it were practicable, would reduce somewhat the proportion of first-born, I think that it is probable, nevertheless, that the figures given here (Fig. 12) of 450 cases of mental deficiency of all varieties except Mongolism represents very nearly the place-in-family incidence. I have excluded Mongolism because this presents peculiarities of ætiology so marked, and in particular, has a place-in-family incidence so peculiar to itself, that it can be more usefully considered apart. I hope to deal with this in my second lecture. A comparison between the percentage of first-born in mental deficiency, 41·7, and that seen in the standard curve (Fig. 6) shows so great an excess of first-born among the mentally defective that even if some reduction should be made for cases due to difficulty of first labour, it is probable that there would

still remain evidence of a special liability of the first-born to mental defect of developmental origin.

Dr. A. F. Tredgold,[3] discussing the part played by abnormalities of labour in the causation of amentia, states that in his opinion "the total number of cases which are the immediate consequence of these conditions is relatively very small, being probably not more than 1–2 per cent. of all aments." He gives reasons for supposing that the proportion attributed to intranatal causes by some observers in special institutions for the mentally defective—e.g., 17·5 per cent., by Fletcher Beach and G. E. Shuttleworth—is too high when applied to mental defectives in general. I would point out, moreover, that although difficulties of labour are undoubtedly more likely to occur with the first-born than with subsequent children, it is not suggested that all the cases attributable to this cause are first-born, so that, at most, the allowance to be made for this factor in the incidence of mental deficiency on the first-born is something less than the total percentage of intranatal causation, and if Dr. Tredgold's figure is even approximately correct, would scarcely affect the significance of my statistics at all. In individual cases I have noted the association of mental deficiency in the first-born with congenital malformations of various sorts, an occurrence which might be expected, if, as I have shown, there is some special liability of the first-born to each of these conditions separately.

Before leaving the subject of mental deficiency I would point out that a very different place-in-family incidence is obtained if Mongolism is included; for Mongolism is remarkable in the lowness of its incidence on the first-born, and as 20–25 per cent. according to Dr. Thomson (with whose figures my own agree—viz., 22 per cent.) of mentally defectives are Mongols, their inclusion would reduce the percentage of first-born considerably (by 10 per cent. in the figures shown in Fig. 12).

EPILEPSY.

The frequent association of epilepsy with mental deficiency led me to investigate the place-in-family incidence of epilepsy. Since I collected my figures this point has been investigated by Dr. Russell Brain,[4] but his figures do not apparently include miscarriages and stillbirths, so that they are not available for the purpose of my inquiry.

The special liability of the first-born to mental deficiency, and the association of mental deficiency with epilepsy gave some *a priori* probability that epilepsy apart from mental deficiency might also be an affection specially attaching to the first-born.

No doubt epilepsy, when associated with mental deficiency, is sometimes the result of some cortical damage, intranatal in origin, which is responsible both for the mental deficiency and for the epilepsy, but this explanation probably applies only to a small proportion of the cases. In a certain number of cases also the mental affection is the result of the epilepsy; but more often the mental condition is of developmental origin, and therefore it seems reasonable to assume that the epilepsy is of similar origin. There is, moreover, corroborative evidence in the not uncommon association of epilepsy with congenital anomalies of other kinds that developmental disturbance is a possible factor in epilepsy even though its manifestation may be delayed until months or even years after birth. The figures which I am able to produce on this point (Fig. 13) are not sufficient to justify any dogmatic statement, but they suggest that there is some special liability of the first-born to epilepsy (38·3 per cent.).

CONCLUSIONS.

To sum up, statistical evidence seems to show that place-in-family is a factor in the causation of disease; and that a first pregnancy carries with it more risk than a later pregnancy of certain affections in the offspring which are due to perversion of development, and so far as can be judged from the variety of the developmental anomalies in which this influence of place-in-family has been traced it may probably be stated more generally that there is a special liability in the first pregnancy to the production of congenital abnormalities.

I would point out that these conclusions are not without some practical bearing. It is no small thing if we can give comfort and hope to the mother and father who are faced with disaster in their first-born, in the shape of some congenital abnormality of mind or body. They are apt to imagine that this is due to some fault or failing which will mar the rest of their married life by likelihood of repetition of disaster if they have further children. It is something to be able to tell them that primogeniture itself is a large factor, possibly the only factor in the production of their misfortune, and that it is therefore highly improbable that any subsequent child will suffer from any congenital anomaly, as indeed experience shows, for the repetition of congenital anomalies in a family, though by no means unknown, is very exceptional.

Linacre Lecture

ON

MULTIPLE NEW GROWTHS.

Delivered at Cambridge on May 6th, 1927,

BY J. A. MURRAY, M.D.EDIN., F.R.S.,
DIRECTOR, IMPERIAL CANCER RESEARCH FUND, LONDON.

WHATEVER aspect of the cancer problem may engage our attention, it is remarkable and significant how readily the discussion reverts to the general problems of nature and causation which are the ultimate subjects of cancer research. Hence it is in practice immaterial which immediate problem is investigated, sooner rather than later, the conclusions arrived at must be considerd in their bearing on the other features of the processes of new growth. For this reason, and because the trend of the experimental investigations in which I have been interested during the last four years has imposed a consideration of the phenomena of multiplicity of neoplasms in single individuals, I have ventured to dedicate this lecture to a consideration of this facies of the cancer problem.

DEFINITION.

It will be remembered that definition and the intricacies of descriptive nomenclature are almost entirely matters of a conventional utility aiming at the avoidance of circumlocution, and the pathologist habitually translates them into their material equivalents. This automatic conversion is not attained without a long apprenticeship and the most profound students of the subject are the most sensible of the pitfalls of ambiguity which lie on every side of the well-worn stereotyped phrases which inevitably intrude themselves into any discussion of the subject of cancer. Hence it comes about that at one time or another structural abnormalities of a trivial kind (often of microscopic dimensions), nævi, sebaceous cysts, nodular aggregations of the elements forming the solid and hollow viscera, have been drawn into or tacked on to, the new growths, and in this sense it is common knowledge that practically no individual is entirely free from manifestations of these processes. This impasse can only be avoided by substituting a kinetic visualisation for the static conception implied in hard-and-fast definitions. When we do this and restrict the new growths *sensu strictiori*, to progressive proliferations essentially of one kind of cell, it is possible to relegate many structural abnormalities, tumour-like in their spatial relationships, to a position

on one side of the neoplasms, keeping their proximity to them at the back of the mind.

MULTIPLICITY OR NEW GROWTH?

The coexistence of more than one new growth in the same individual has been observed and recorded on many occasions, and in recent years renewed attempts have been made to appraise its frequency by a systematic examination of the abundant material provided by the post-mortem records of large hospitals over a longer or shorter period. As was to be expected, niceties of definition have had to be introduced both as to what could legitimately be regarded as multiplicity, and what new growth. The definition of multiplicity is complicated by the inclusion in the group of new growths of two natural divisions which merge into each other, mainly distinguished by their clinical course or (to use the modern jargon) biological behaviour—viz., benign and malignant. The benign new growths progress slowly and remain localised, the malignant increase in size rapidly, encroach on their surroundings, and disseminate to remote parts of the body giving rise to metastases. In general, primary multiplicity is so common in the benign neoplasms that it is frequently regarded as presumptive evidence of the benign character of the new growths in which it is encountered. The malignant new growths, on the other hand, are usually solitary, and the late occurrence of multiple foci in those the subject of them is most frequently due to dissemination of living cells from the primary focus by the vascular channels.

Varieties of Multiplicity.

We have, therefore, to distinguish between the following varieties of multiplicity:—

1. More than one benign new growth in the same individual (*a*) of one tissue or organ, (*b*) of separate tissues or organs.

2. More than one malignant new growth in the same individual (*a*) of one tissue or organ, (*b*) of separate tissues or organs.

3. Benign and malignant new growths in the same individual.

From the slow progress and long duration of benign growths it follows that when they occur in combination with malignant tumours the benign tumour has in most cases antedated the malignant and, therefore, it may be more instructive to state the problem in the general form of the development of a second neoplasm in an organism already bearing one. Unfortunately, when dealing with post-mortem records it is obvious that it is only rarely that information is available from the history of the patient permitting a clear statement of the priority of one tumour over the other. More or less cogent inference is as much as can be expected and the collected data are quite unsuitable for statistical treatment. Hence it comes about that the published statements take the form of percentages of multiple neoplasms in the total number of autopsies in which the presence of a tumour is recorded. One of the most recent of these studies is by Puhr (1926) on the post-mortem material for the preceding 21 years of the Second Budapest Pathological Institute. In this material of 6718 necropsies there were 1559 cases with tumours and of these 219 cases presented multiple growths—i.e., 14·04 per cent. of the tumour cases. The detailed tabular analysis is divided up according as two, three, four, or five new growths were present.

Two Tumours.

Carcinoma with carcinoma	2
„ „ sarcoma	1
„ „ benign tumour	0·80
Sarcoma „ „	0·12
Benign „ „	0·52

Three Tumours.

Three benign tumours	11

Four Tumours.

Carcinoma with carcinoma with two benign tumours	1
„ „ „ three „	6
Sarcoma	1
Four benign tumours	5

Five Tumours.

Carcinoma with four benign tumours	3

Puhr draws the conclusion from the assembled data that multiplicity in the sense indicated in his tables is common enough to indicate a definite tumour diathesis, inborn or acquired, in those the subject of new growth. As can be seen, however, the main weight of this conclusion derives from the frequency of benign new growths, and it is remarkable that only five cases of multiple malignant new growths occurred out of 1559 tumour autopsies in 21 years—i.e., one every four years. It is unfortunate that Puhr has not given the number of malignant cases as distinguished from tumours generally in this total, but it seems fair to conclude that multiple malignant new growths are relatively rare. A certain interest attaches to the fact that in none of Puhr's five cases of multiple malignancy did the combination carcinoma mammæ and carcinoma uteri occur. Some years ago, when my attention was first directed to the study of multiple malignant growths, Prof. Udney Yule was good enough to make a preliminary statistical analysis of the probability of this combination occurring, on the basis of the English mortality statistics, for females. The guarded conclusion he arrived at was that the combination ought to occur in 2½ per cent. of cases if there were no mutual interference of new growth in the one organ with its incidence in the other. As cancer of these two sites make up nearly half the total female cancer mortality, it is hardly possible such a combination could be consistently overlooked, and its absence from the casuistic literature is probably significant. Tabular statements of the same kind have been compiled by Egli, Harbitz, and others. Egli records primary multiplicity in 263 (27·2 per cent.) of 966 tumour autopsies in seven years' material of the Basel Pathological Institute. In 20 cases multiple malignant growths were present. Harbitz found 16 examples of multiple malignant growth in 524 cancer autopsies (1900–15), roughly 3 per cent. Out of a much larger material (4219) examined in the Oslo Institute for the Norwegian Cancer Committee 32 examples of multiple malignancy (1 per cent.) were encountered. In most cases an interval of from five to 23 years elapsed between the development of the two tumours. Both Egli and Harbitz conclude also from the frequency of the combinations, benign and malignant, that a hereditary predisposition to tumour growth must be assumed to occur. The combination carcinoma mammæ and uteri is again conspicuously absent, and it is notable that throughout, the simultaneous presence of two of the commoner forms of cancer is rare. Usually one of the growths belongs to the group of pathological curiosities or rarities—forms which are so seldom met with that it is natural to assume an exceptional concurrence of causal factors in those the subject of them. The variations in frequency of cancer of the several organs of the body in the different races of man and animals may in part depend on the factors which limit the occurrence of multiple malignant new growths. It is pertinent to consider whether the greater incidence of carcinoma mammæ in England than in Holland, being balanced by a higher incidence of alimentary tract cancer in Dutch females producing the same total cancer mortality in both countries, may not be brought about by some such inhibitory mechanism as is here hinted at, and Neve's experience of the predominance of Kangri cancer in Kashmir (2000 out of 3000 operations) points in the same direction. It is hardly conceivable that chronic irritation of the genital and alimentary tracts which in Europe predispose to cancer of these organs should be inoperative in Kashmir.

The earlier authors viewed the problem from a somewhat narrower angle and mainly confined their

attention to the occurrence of multiple carcinomata or at most multiple malignant growths, usually of separate organs. When we recollect the violence of the controversy which raged among pathological anatomists on the unicentric and multicentric origin of carcinoma, this restriction of the discussion of multiplicity to new growths of separate organs is understandable. When we come to deal with the problem in its experimental form, the objections which are so formidable in the analysis of post-mortem material largely vanish. They were so real to the earlier workers that Billroth, for example, refused to admit primary multiplicity of malignant new growths unless: (1) the tumours had a different structure; (2) each tumour could be derived histogenetically from its own mother tissue; (3) each tumour produced distinctive metastases.

BENIGN AND MALIGNANT GROWTHS.

It was the impossibility of carrying out rigorously all three of Billroth's criteria that led to the widening of the survey to include benign as well as malignant growths. The problem lost in precision by this extension of the terrain and it may not be unprofitable to consider for a moment the reasons for this diffuseness. It is now generally agreed that the benign and malignant new growths form a natural group—they are manifestations in varying degree of the same process, and it might at first sight be supposed that it would be immaterial in investigating multiplicity of neoplasms whether benign or malignant tumours made up the combination. If, however, we accept the community of nature of the benign and malignant new growths, we must recognise that the malignant possess the attributes of the group in higher degree, and if systemic effects are produced by new growths of every kind they may easily be of such slight intensity in the case of the benign tumours that the means at our disposal may be insufficient to reveal them. On the other hand, the most malignant tumours may be the result of such an intense degree of action of the causative agency or agencies that it overcomes the influences which the pre-existence of another neoplasm (especially a benign tumour) may be presumed to oppose to it.

To escape from this dilemma we must in some way secure a simplification of the material for consideration. The most obvious restriction is to consider the occurrence of more than one tumour of the same kind in the same organ or tissue. The frequency of primary multiplicity of benign tumours of the skin and its appendages, and of the alimentary tract, of the connective tissues, and of nerve trunks, enables us to dismiss this aspect of the problem summarily. Little or no mutual interference is established by benign tumours to each other's inception or continued proliferation.

The investigations of Puhr, of Egli, and of Harbitz leave little doubt that benign tumours similarly induce little or no resistance to the development of malignant growths. In certain situations the converse would seem to be true. Thus it has frequently been observed that carcinoma of the colon has developed by an apparently progressive transformation of one only, of multiple pre-existent papillomata. Occasionally one of a number of fibromyomata of the uterus takes on a more rapid tempo of proliferation and manifests the other classical features of malignancy. The most instructive examples are met with in the occupational forms of cancer—tar, paraffin, X ray cancer. In these a preliminary condition is the occurrence of chronic dermatoses ending in benign warty proliferations. When malignant growth supervenes it usually takes its origin in one of these warty hypertrophies, and it is not uncommon to find that the operative removal of the malignant wart is followed after an interval by a similar transformation of others till then quiescent, after an interval more or less prolonged. When this happens it is pertinent to inquire why the change does not supervene in all the papillomata of the region at once, and a possible explanation of this discrepancy will be referred to later in discussing certain features of the growths produced in the experimental investigation of tar cancer in animals.

The laborious investigation of early cases of cancer of the skin, stomach, and breast has finally resolved the controversy, which has already been referred to, over the alleged unicentric or multicentric origin of carcinomata in these sites, in the sense that in the great majority of cases the final solitary character is secondary to a primary multifocal condition which ends in a single tumour by coalescence of adjacent independent foci. It is essential to keep in mind that in most cases where an exact judgment is possible the original foci are distinct and finally abut on each other and coalesce by intrinsic increase in size and not by progressive transformation of the intervening non-malignant epithelium. When the latter apparently occurs it is invariably accompanied by such a diffuse hypertrophic condition of the whole epithelium in the area concerned that the microscopical appearances are equivocal. Here again it is not easy to see why this disjunctive state of independent adjacent centres should exist on any hypothesis of the causation of the malignant process. In this primary multiplicity the malignant tumours show a community of character with the benign, the difference mainly being that in the benign the process interests a more extended area, frequently a whole system (as in v. Recklinghausen's neuro-fibromatosis), whereas the primary foci of the malignant tumours are grouped together in a restricted area. The tumours which are intermediate in character between the benign and malignant occasionally bridge this gap, as has been clearly shown for some of the rodent ulcers; primary multiplicity over a fairly wide area is not unusual in them, and sometimes a successive development of new foci at the periphery of a larger pre-existent growth can be clearly demonstrated.

TAR CANCER.

The problems presented by the occurrence o primary multiplicity in cancer are thus seen to b complex. The solitary character of the cancers o most organs is seen to be secondary, due to the fusio of a varying number of closely packed initial foci the remainder of the organ, even when the site of th antecedent pre-cancerous hypertrophic changes remaining free from independent malignant trans formation. The fact that in some forms of cance especially of the occupational varieties, the remova of the first developed focus may be followed, afte an interval more or less prolonged, by the recrudescenc of the disease in the adjoining area, suggests tha the whole area was prepared for the malignan change and somehow held in check by influence emanating from the first frankly malignant focu The time and intensity relations of the hypothetica causative agencies in the cancers occurring naturall in man are, however, so inaccessible to analysis tha the most minute scrutiny of the conditions obtainin at operation or after death only leads to a balancin of probabilities little removed from complete ignoranc The only possible way in which advance can be hope for is by experiment, and the means at our dispos at the present time centre round the reproduction i animals of the occupational forms of cancer occurrin in man as the result of long-continued action of t and other products of the destructive distillation coal. The combined results of the investigations of host of workers during the last ten years perm of the following general statements on tar cancer laboratory animals. The different species are unequal susceptible to the carcinogenic action of tar. T mouse and the rabbit are the most suceptible; t rat, guinea-pig, and domestic fowl are much le easily made the subject of cancer by the extern application of tar. When a large series of mic for example, are treated, individual differences reve themselves, a few rapidly become cancerous, t majority of the remainder develop the disease aft a longer interval, and a small refractory resid remain free from the disease even after prolong

intensive treatment. The length of time which elapses varies with the frequency of the applications within rather narrow limits. If tarring twice or three times a week results in malignant growth after four and a half to nine months, tarring once a week usually stretches out the preparatory period to 10 to 12 months at least and the refractory remainder is larger. A few susceptible animals may develop cancer after a long latent period in consequence of a single application of hot tar.

Variations in the extent of the area to which the tar is applied introduces a most interesting difference in the result. If the tar be applied to a very small area (2–3 mm. in diameter) the neoplasm arises at this point and is usually solitary, although crowded minute foci may be distinguished on microscopical examination of very early growths just as was seen to occur in many human cancers. If a larger area is tarred—for example, the whole of the skin of the back—multiple papillomata appear scattered over the surface with relatively unaltered areas of epithelium between. Not all of these apparently benign proliferations go on to definite malignant growth. Usually one or two forge ahead, grow rapidly, and produce infiltration and metastases in the classical manner. If two widely separated small areas are tarred simultaneously, two growths appear at the same time and progress at much the same rate. It is clear from this rapid summary that we have in the experimental tar carcinomata an almost perfect reproduction of the sequence of changes which characterise the biology of malignant tumours in man with the inestimable advantage that the duration and intensity of the antecedent stimulation are under control and definitely known.

In the attempt to analyse the forces in play determining the malignant transformation at one point in the treated area and holding it in abeyance at another, many variants of the fundamental experiment have been carried out. The first of those to which attention may be directed consists in tarring a small area till carcinoma develops, removing the tumour widely by operation, and beginning again in an area of unaltered skin. *A priori* one might expect either that the same duration of tarring would result in a fresh carcinoma being produced or that a shorter period of treatment might be sufficient. In the experiments I have carried out along these lines the result has been that a greatly increased resistance is encountered and only microscopic hypertrophic changes have been produced. The same indifference to tar painting manifested itself in mice from which mammary carcinomata had been removed by operation. It would seem that the development of malignant growth brought in its train a disability of the remainder of the organism, such that a course of treatment which would produce carcinoma in a normal animal was without result.

An experiment of intermediate character between simultaneous tarring of separate areas and successive tarring after removal of the tumour first produced gave remarkable results. The second tarring was begun two or three months after the first and before any proliferative changes had supervened. Two totally different results were obtained. In some animals the site of the first tarring developed carcinoma after the usual delay, and the second site remained refractory even after a longer period of tarring. In the animals in which cancer appeared either very early or very late at the first site, a second primary growth appeared at the second site either at the same time or within a month—that is, an interval less than the difference in the duration of tarring at the two sites. I have summarised these contrasted occurrences in the statement that there is a phase in the development of these skin tar cancers before the resistant condition supervenes, in which the skin more easily responds with cancerous proliferation. In other words, the experimental achievement of primary multiplicity of tar cancer in mice is mainly determined by the duration and intensity of the stimulation at the selected areas, and systemic changes affecting the sensitiveness of the remainder of the body are produced by the tumour which develops first.

The experiments of Deelman illuminate another facet of this obscure problem. Deelman has shown that if the whole dorsal surface of mice is tarred till papillomatous nodules are produced the intervening areas of skin, which if left to themselves would remain quiescent, can be awakened to vigorous malignant proliferation by the introduction of a fresh stimulus of another kind—the regeneration of wound healing. Incisions adjacent to the slowly growing papillomata heal promptly, and then all along the scar new rapidly growing nodules of carcinoma make their appearance and soon outstrip the pre-existing papillomata. It is as if the efflorescence of the papillomata had set up in their neighbourhood an inhibition which could be raised by the stimulus to cell division of wound healing.

An experiment of a different kind carried out by my colleague, Dr. Cramer, shows the influence of an apparently unrelated intervention on the ease of induction of tar cancer. Cramer excised the spleens from a number of mice, minced them up separately, and returned each to the peritoneal cavity of its own mouse. The animals so prepared showed a considerable acceleration of the induction of tar cancer as compared with normal animals, the times of appearance of the tumours in the two series showing a shift of about two months in favour of splenectomised. The nature of the influences at work in these experiments, whether favouring or hindering the development of cancer, are still unknown but are being made the subject of experiment. The attempt has been made to obtain the resistant state, on the basis of Gye's virus conception of tumour ætiology by immunising mice with fresh or incubated tumour from mice and other species of laboratory animals. So far no retardation of the induction of tar cancer has been seen. Whatever may be the ultimate outcome of the analysis of the phenomena accompanying the production of multiple experimental tar cancer, it is clear that these investigations must precede a precise conception of the reasons for the occurrence of primary multiplicity of cancer in man. Given the possibility of its occurrence, the actual capriciousness encountered is more easily entertained by the mind, if the result in individual cases is ascribed to the balanced action of several factors, some of which favour and some hinder its occurrence.

The only analogies which exist for the apparent inhibition of a second primary lesion occur in some of the infectious diseases, and it is important to keep in mind that even if the resemblance were closer than it is it need not necessarily be evidence in favour of the microbic origin of tumours. The feature referred to is that well exemplified in the infection of syphilis that the characteristic primary lesion, or chancre, cannot be produced in a patient or animal already infected. The same is true of vaccinia, but in the latter infection another phenomenon occurs when the attempt is made to infect an immune individual, that a greatly increased transient reaction occurs. It is possible that this allergic reaction may have something in common with the curious hypersensitiveness leading to acceleration in carcinogenesis mentioned in connexion with the double tarring experiments already described. Whatever may be the ultimate explanation, the opinion may be hazarded that the analysis of the factors favouring or hindering multiplicity of malignant new growths is bound up with the final elucidation of their nature and causation.

GASTRO-JEJUNO-COLIC FISTULAS:

REMARKS ON SIX CASES.

BY IAN MACDONALD, M.D. EDIN. & PARIS.

THE gastro-jejunal or anastomotic ulcer in approximately every fifth male patient slowly perforates into the colon. The onset of this dire sequel of gastro-enterostomy is announced by four cardinal symptoms—diarrhœa, fæcal vomiting, foul eructations, and variable pain. Pain may be absent; diarrhœa is often the initial and continuous symptom.

The clinical diagnosis is seldom doubtful; confirmation may be obtained by X ray examination, when the most important sign is rapid emptying of the stomach and immediate filling of the transverse colon. The pitiable state of the emaciated patients and their profound weakness may simulate malignancy, but the horrible vomiting with its characteristic odour leaves no doubt as to the diagnosis. Operation in view of the fatal prognosis is imperative; its extent will depend on the permeability or otherwise of the pylorus and the state of the patient.

If after the original operation the pylorus is patent the minimum operation may be performed, separation and closure of the three cavities. If the pylorus is still obstructed a new gastric outlet must be provided. Gastro-duodenostomy may be possible or partial gastrectomy may be selected, but the state of the patient may compel the surgeon to another gastro-enterostomy. Theoretically gastro-enterostomy, the cause of the gastro-jejunal ulcer, should be banned; practically it may be necessary.

Difficulties of Operation.

The difficulties inherent to these operations and the risk of sepsis fully recognised by all surgeons make Pauchet[1] recommend in difficult cases the removal en masse of the right colon and the fistula, the right half of the stomach, and the jejunal loop without opening any of their cavities. He advocates this method as easier for the surgeon and safer for the patient in cases where the inflammatory mass is large and the colon strictured, when the ascending colon is dilated, and if the middle colic artery is accidentally injured. After a Polya-gastrectomy and the removal of the colon, to save time in weak patients, he advises that the sections of the terminal ileum and transverse colon should be left in the wound after Mikulicz's method. The artificial anus is closed some weeks later. We have no experience of this immediate radical operation, though in one case a wound of the middle colic artery forced us to a segmental resection of the transverse colon.

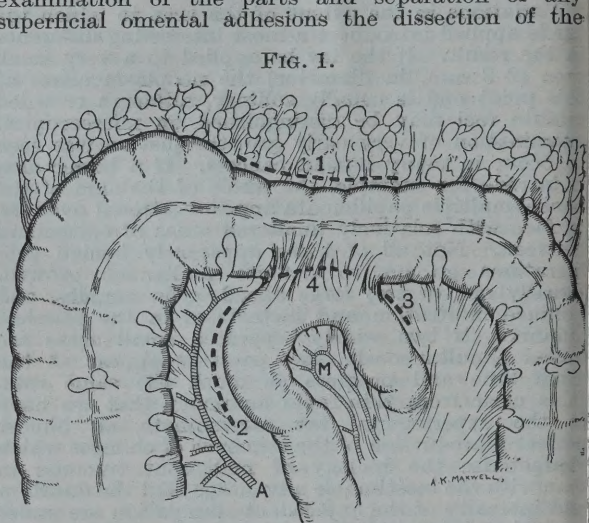
The pathology of these fistulas varies considerably. If adhesions are few the attached viscera are easily defined, but they may be buried in an inflammatory mass, so that resection of a portion of the transverse colon may be the minimum operation possible. The condition of the colon is important, for a certain degree of stricture may occur at the fistula; distally, then, the bowel is narrowed while the proximal portion is dilated and full of fæces. If resection of the colon becomes necessary the disparity between the two portions may render axial anastomosis difficult and inadvisable. The jejunal loop also contains fæces, and during its separation from the colon precautions must be redoubled to avoid soiling of the operative area.

Technique.

In the complicated operation necessary personal methods and experience will guide the surgeon. In the preoperative treatment lavage of the stomach with weak iodine solution has given us the best results. For some days previously opium is given, and the patient is allowed full diet up to the day before the operation. The anæsthetic will be selected in view of a prolonged operation in a debilitated patient. No anæsthesia has given us such satisfaction as intravenous somnifene by Fredet's[2] method combined with 6 to 8 oz. of a ½ per cent. solution of novocaine without adrenalin in the wall and peritoneum.

In our last three cases we have used this method; a trifling amount of chloroform or ether has been necessary to close the abdominal incision. If the original incision has been right paramedian we have found it best to open the abdomen in the middle line or slightly to the left, for the inflammatory mass is anchored towards that side by the short loop. After examination of the parts and separation of any superficial omental adhesions the dissection of the

FIG. 1.



1, 2, 3, 4, lines of dissection. A, middle colic artery. M, mesentery

viscera is begun, the operator's aim being to reproduce the original opening in the mesocolon by working from the periphery towards the fistula at the centre. The separation may begin by omental-colic cleavage on the upper surface of the colon or, by clearing a space in the gastro-colic omentum, to define the upper surface of the transverse mesocolon from this position. All adhesions should be divided carefully between ligatures to avoid bleeding which obscures the field.

The under surface of the mesocolon is then exposed by lifting the colon upwards. The mesocolon is carefully incised or scratched through to the right of the anastomosis, while adhesions between it and the stomach are separated by the gloved finger and the lightest strokes of the knife. The position of the loop of the middle colic artery must ever be kept in mind. If the gastro-enterostomy has been made towards the left in the mesocolon the vessel will be found first to the right of the anastomosis, then it lies hidden under the overhanging colon. The upper edge of the afferent loop should also be well defined and above it an opening may be made in the mesocolon here. As the area of cleavage advances between the mesocolon and the stomach it may be possible to pass the finger from the incision on the right behind the anastomosis to the space above the afferent loop. This manœuvre is helpful, for the finger takes the place of a supporting clamp. Balfour [3] also calls attention to its value.

The area situated below the afferent and efferent loops should obviously be avoided, for the vessels in the mesentery if injured cause troublesome bleeding. The jejunum is now separated from the colon by an incision along the line of adhesion. The colon when free is turned upwards and at once sutured, the openings in the stomach and jejunum being temporarily closed with a clamp and Chaput's forceps. A compress is laid in the opening of the mesocolon while the bowel is sutured transversely to avoid narrowing of its lumen. A guide suture is first passed at each end of the rent in the colon; traction is made on these to define the line accurately. The lowest of these sutures must be carefully placed to ensure closure of this more inaccessible angle. The mucous membrane of the fistulous colon is sometimes thick and œdematous, and is best avoided in the sutur

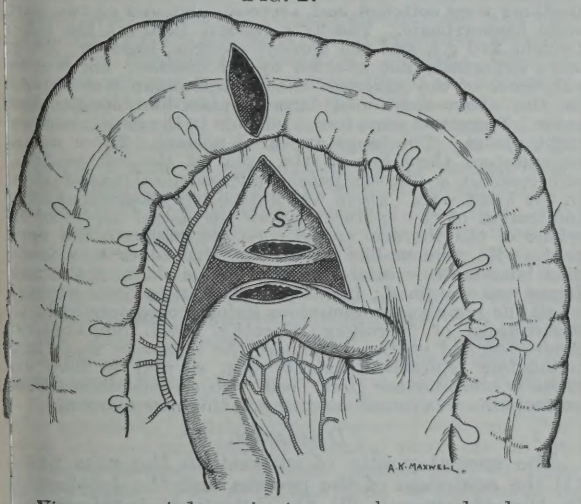
line; if included, a septic ridge remains in a closed cavity under the serous suture, favouring leakage and disunion. It is therefore inverted by passing the sutures only through the serous and muscular layers. The suturing of the irregular aperture is possibly done more accurately by separate sutures closely placed; the first layer is covered by a second; the whole circumference of the colon is then loosely wrapped in a collar of omentum brought through the opening in the mesocolon. The jejunum, separated from the stomach, is next sutured, also transversely, the angles of the opening being also carefully defined by guide sutures. Narrowing is further avoided by the bite of the needle being very near the edges of the incision.

The stomach opening is finally sutured in its long axis by a double or triple line, unless it is required for a new gastro-enterostomy. At this stage, when necessary, the new stomach outlet is made, the method being selected which the surgeon decides is best. The opening in the mesocolon, if not needed for gastro-enterostomy, is closed by a couple of sutures. The important point as to the need of cæcostomy now arises; some surgeons consider it advisable even with simple suture of the colon to avoid tension on the suture line, "when the suture of the transverse colon has been difficult and perhaps imperfect" (Balfour[3]). We have not yet employed it, but should segmental resection of the colon be necessary we consider cæcostomy essential, unless, as in our third case, a temporary anus is made near the site of the resection to rapidly terminate an operation already prolonged in a weak patient.

Results.

Operations for gastro-jejuno-colic fistulas, in spite of their complexity and the poor condition of the patients, do not show a high mortality, for in 27 cases

FIG. 2.



Viscera separated, opening in mesocolon reproduced. "S" stomach.

quoted by Bolton and Trotter [4] only six died. More recently in 20 operations at the Mayo Clinic [5] four died after the operation. But according to Loewy's[6] statistics in 63 operations of all kinds there were 11·9 per cent. of cures, 11·1 per cent. definite recurrences, and 27 per cent. of mortality.

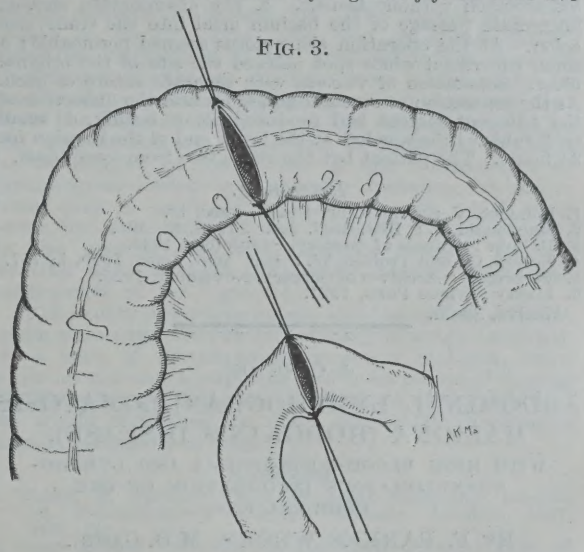
The six cases under our care all recovered, but two required further radical measures. The fistulas in all cases followed posterior gastro-enterostomy, in two cases performed elsewhere, and in two cases an entero-anastomosis had also been made. Two fistulas were jejuno-colic, in the others the colon opened directly into the anastomosis. The youngest patient was 36, the oldest 58. Their clinical histories and the operations performed for their relief are briefly recorded below. I am indebted to Mr. A. K. Maxwell for the sketches.

Clinical Records.

CASE 1.—Posterior gastro-enterostomy for pyloric stenosis seven years previously. The fistula symptoms were a painless diarrhœa and foul fæcal vomiting. At the operation the pylorus was found narrowed. The gastro-enterostomy was free and supple; the fistula was found between the efferent loop and the colon. Separation of the viscera and closure of each was performed, then a new outlet made by anterior gastro-enterostomy with entero-anastomosis. This patient at the present time, seven years later, is in perfect health.

CASE 2.—Posterior gastro-enterostomy for pyloric stenosis ten years previously, followed by a gastro-jejunal ulcer five

FIG. 3.



Transverse suture of colon and jejunum.

years after the anastomosis. Resection of the anastomosis and a new posterior gastro-enterostomy with entero-anastomosis were performed; five years later patient readmitted in a state of extreme cachexia with fæcal vomiting and diarrhœa. Separation of the viscera, resection of the entero-anastomosis, a new gastro-enterostomy with entero-anastomosis being made on the opening in the stomach. The pylorus still showed narrowing. This patient six years later reports that he is eating and drinking everything, and is quite free from gastric symptoms. His case illustrates the well-known tendency of certain patients to ulceration.

CASE 3.—Posterior gastro-enterostomy ten years before for pyloric stenosis; readmitted complaining of profound weakness, foul vomiting, and diarrhœa. At the operation some ascites was found and peritoneal tuberculosis commencing. During the separation of the viscera the middle colic artery was injured and resection of about six inches of the transverse colon became necessary. The narrowed distal end towards the splenic flexure was closed by a purse-string suture. The much dilated proximal portion was anastomosed laterally about four inches from its section to the distal part already closed, and its open end shut by a Kocher's forceps fixed in the abdominal wound. The forceps were removed 36 hours later, but the bowel functioned freely through the anastomosis 48 hours after the operation. No fæces passed by the artificial anus for ten days. One month later the artificial anus was closed by an extraperitoneal operation. This patient returned two years later looking well, but with a considerable ventral hernia and evident gastric retention from a narrow pylorus. The hernia was repaired, the dilated attached colon separated from the wall, and an anterior Polya-gastrectomy with entero-anastomosis was performed. The patient made a good recovery.

CASE 4.—Two years previously posterior gastro-enterostomy and entero-anastomosis for duodenal ulcer adherent to the liver. A year later began to complain of pain, profuse diarrhœa, and wasting without vomiting. At the operation the colon was found fixed to the abdominal wall. The efferent loop was much inflamed, a thickened mass fixing it to the colon; from this point a slight hardness passed along the anastomosis. Separation and closure of the viscera. The ulcer and peri-duodenal adhesions were still present and in addition we discovered a large dilatation of the third part of the duodenum overlooked at the previous operation. The patient's state on the table prevented further measures being taken at the time. He recovered from the operation but continued to have some gastric discomfort.

CASE 5.—Gastro-enterostomy two years previously for duodenal ulcer. Ten months after this operation had an attack of pain accompanied by melæna. The symptoms of the fistula were frequent diarrhœa and fæcal eructations without vomiting. At the operation the pylorus and duodenum seemed normal, so the viscera were simply separated and closed. The patient a year later was in excellent health and had gained about a stone in weight.

CASE 6.—Posterior gastro-enterostomy seven years previously for duodenal stenosis. Very soon after the operation discomfort began, which gradually increased till the symptoms changed to diarrhœa and foul fæcal eructations. Vomiting was rare. The patient had been washing his stomach without benefit. X ray examination showed immediate passage of the barium meal into the transverse colon. At the operation the pylorus seemed permeable; a small superficial white spot marked the site of the original ulcer. Separation of viscera, with separate suture of each. As the separation of omental adhesions and the dissection of the adherent viscera had produced some oozing, a small split rubber tube was left at the lower end of the incision for 24 hours. The patient left the clinic free from symptoms.

A CASE OF

ABDOMINAL LYMPHOGRANULOMATOSIS MALIGNA (HODGKIN'S DISEASE),

WITH HIGH BLOOD-EOSINOPHILIA AND LYMPHO-GRANULOMATOUS INFILTRATION OF THE EPIDURAL FAT.

BY F. PARKES WEBER, M.D. CAMB., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO THE GERMAN HOSPITAL, LONDON;
AND
O. BODE, M.D. BERLIN, M.R.C.S. ENG.,
HOUSE PHYSICIAN TO THE HOSPITAL.

THE case to be described was that of a young Englishman, H. W. M., a printer, aged 36 years, admitted to the German Hospital on April 23rd, 1927.

Clinical History.

Three weeks before admission he had begun to suffer from severe pains in the region of the left shoulder, gradual loss of strength and cachexia, with muscular weakness in the arm of the painful side. Previously to that he had apparently enjoyed good health. The Wassermann and Pirquet reactions were negative, and the intracutaneous reaction with an echinococcus antigen was likewise negative. Examination (including Rontgen ray examination) of the thorax showed nothing abnormal. There was considerable general wasting, but the wasting was slightly more marked in the left upper limb than in the right. All the deep nervous reflexes on both sides were "active," but those in the left upper limb rather more so than those in the right. (It should be remembered in this connexion that all the deep reflexes are often exaggerated in chronic cachectic wasting subjects.) The knee-jerks on the two sides were equal. Babinski's sign was negative on both sides. Ophthalmoscopic examination showed nothing abnormal.

In the hospital, owing to the presence of a chronic sometimes remittent and sometimes intermittent type of pyrexia (up to about 101° F. in the afternoons) and a high blood-eosinophilia (up to about 40 per cent. of the white cells), and in the absence of any obvious cause for a high blood-eosinophilia, the possibility of early lymphogranulomatosis maligna was thought of, but enlarged lymphatic glands could not be detected anywhere. The liver was not enlarged and the spleen could not be felt. A few days after admission, however, a rather small, hard, immobile mass could be felt by deep palpation a little to the left of the centre of the abdomen, possibly arising from retroperitoneal lymphatic glands. The pain in the left shoulder and the weakness in the left upper limb were no longer complained of, but in May there was considerable lumbar pain, probably connected with the abdominal "tumour" (which later on, at the post-mortem examination, was found firmly adherent to the vertebral periosteum, doubtless having been pressing on and commencing to erode the vertebræ). The "tumour" rapidly increased, until it became almost as large as a man's head, whilst the patient became extremely emaciated and progressively weaker. He died on June 18th, 1927, about 11 weeks after the first symptoms of the disease were complained of. At the end there was a small non-sanguineous serous effusion in the right pleura.

The diagnosis of lymphogranulomatosis maligna was further confirmed a little before the patient's death by the development of intense general cutaneous pruritus with scratching. Owing to occult blood in the fæces the presence of intestinal ulceration of lymphogranulomatous nature had been likewise suspected.

Following are blood-counts made during life:—

Date in 1927.	Hæmoglobin per cent.	Erythrocytes per c.mm.	White cells per c.mm.	Eosinophils per cent.	Polymorpho-nuclear neutrophils per cent.	Lymphocytes per cent.	Monocytes per cent.
April 25th..	63	4,584,000	9,200	20	58	15	7
May 5th ..	—	—	—	45	37	11	7
May 10th ..	60	4,496,000	8,300	26	59	7	8
May 23rd ..	61	4,400,000	6,900	34	56	8	2
June 14th ..	75	4,400,000	11,000	36	53	7	4

Repeated blood-counts early in May showed an eosinophilia averaging 40 to 50 per cent. of the total white cells. The thrombocyte-count (May 12th, 1927) was about 270,000 per c.mm. of blood.

The treatment was arsenical. Rontgen ray treatment at another hospital was advised, but when a vacancy occurred he had temporarily left our hospital and missed the chance. He was much worse when readmitted five days before his death. He was away from May 30th to June 13th.

Necropsy.

Examination showed a conglomerate mass of enlarged lymphogranulomatous and partly necrotic retroperitoneal lymph glands, firmly adherent to the vertebral column, almost as large as a man's head, together with two ulcerated lymphogranulomatous plaques in the wall of the jejunum. On section (macroscopically) the conglomerate mass appeared lobulated, and in most parts it was white and hard, but portions were softened and necrotic, and one or two parts were hæmorrhagic. The liver (weight 1260 g.), the spleen (weight 240 g.), and the kidneys (weight, together, 350 g.) were apparently not affected by the disease; nor was the substance of the pancreas, though this organ was included in the above-mentioned large tumour-like conglomerate mass. There was some serous effusion in the peritoneum and right pleura. The lungs appeared normal. There was an antemortem thrombus in the apex of the left ventricle adherent to a fibrotic patch (microscopical examination) in the heart wall. There was diffuse lymphogranulomatous infiltration of the epidural fat on the dorsal aspect of the whole of the thoracic spinal cord, especially in the upper part. No tumour-like growth in the bones was found. The bone-marrow in the middle of the shaft of the right femur was examined; it was red. The microscopic structure of all the lymphogranulomatous lesions corresponded to the descriptions of Sternberg, Dorothy Read, Sir Frederick Andrewes, and others. Amongst the cells were many large uninuclear (epithelioid) giant cells, as well as here and there a multinuclear giant cell. No striking local (tissue) eosinophilia was found excepting in the bone-marrow.

Discussion.

The special points of interest in the case were (1) the acuteness of the process and the localisation in the abdomen; (2) the intestinal involvement; (3) the high blood-eosinophilia and the intense pruritus at the end; (4) the lymphogranulomatous infiltration of the epidural fat.

(1) *Acuteness of the Process and Localisation in Abdomen.*—Although the retroperitoneal lymphatic glands were probably affected for some time before the onset of subjective or objective symptoms, the process was extremely acute when compared to most other cases of the disease. Nevertheless, cases of so-called "acute Hodgkin's disease" have been described by various writers, and by one of us (F. P. W.) many years ago.[1] The retroperitoneal lymphatic glands are often affected in lymphogranulomatosis maligna, but they are relatively seldom the first group of glands to be affected. In cases in which they were apparently primarily affected—so-called "abdominal Hodgkin's disease"—the main symptom during life has sometimes been a periodic pyrexia of the Pel-Ebstein type,[2] and

diagnosis of Hodgkin's disease has not always been made during life, at all events in the early stages, when the superficial lymphatic glands were not enlarged and when no definite swelling in the abdomen could be made out. It has been suggested that in cases in which the abdominal glands are first affected the unknown microbic agent of the disease has entered the body by way of the alimentary canal. Whether this suggestion be correct or not, it is highly improbable that in the present case the relatively small lympho-granulomatous plaques in the jejunum represented the primary infection or "port of entry" of the disease. Another question is whether the present case could be called one of "Hodgkin sarcoma" (after J. Ewing) as distinct from "Hodgkin granu-loma."[3] This we would leave undecided.

(2) *Intestinal Involvement.*—The intestine is rarely involved by the lymphogranulomatous process, but in the unpublished case of a man in the prime of life kindly described to us by Prof. W. Bulloch, the intestinal involvement led to such extensive intestinal ulceration as to hasten the fatal termination.

(3) *High Blood-eosinophilia and Intense Pruritus at the End.*—Local eosinophilia ("hist-eosinophilia") in lymphogranulomatosis maligna is sometimes extreme as it was in a case of mediastinal localisation described by Weber and Ledingham,[4] though in that case the blood-eosinophilia ("hæm-eosinophilia") was not above 10 per cent. in the differential count of the white cells at the times when the blood-counts were made. The collected results of clinical and experimental observations on the subject of eosino-philia make it seem probable that in local eosinophilia the eosinophil cells are carried to the affected parts by the blood stream from the bone-marrow, and that they are probably derived from the eosinophilic myelocytes in the bone-marrow. Eosinophilia is to be regarded as part of a general, protective, allergic reaction towards the presence in the body of foreign proteins or abnormal products of albuminous catabolic metabolism within the body. The extensive necrotic changes in lymphogranulomatosis maligna (due to the lymphogranulomatous process itself) are probably the cause of the local and general (blood) eosinophilia observed in varying degrees at various stages of the disease. Nevertheless, a persistent high blood-eosinophilia, such as was a feature of the present case, is very rarely met with. In the above-mentioned case, of which Prof. Bulloch kindly told us, there was for a time a still higher blood-eosinophilia than in our case, and in that case, as in ours, the lympho-granulomatous process had likewise involved the intestine. It may turn out that in the very rare cases of lymphogranulomatosis maligna with excep-tionally high blood-eosinophilia the intestine is invariably involved. Probably the intense universal pruritus constituting the most striking clinical feature of certain cases of lymphogranulomatosis maligna—the so-called "prurigo lymphogranulomatosa"[5]—is due (like eosinophilia) to harmful products of the lymphogranulomatous process circulating in the blood stream. The pruritus, when it occurs, is a characteristic symptom of early stages of the disease, seldom occurring in the final stages. A very high blood-eosinophilia, when present, may disappear in later stages of the disease, as it did in the above-mentioned case of Prof. Bulloch, the protective "eosinophilic mechanism" (if we may use the term) having perhaps become worn out or exhausted.[6]

It may be noted that a sometimes valuable blood-sign in early Hodgkin's disease—namely, a leuco-cytosis of the polymorphonuclear neutrophils—was absent in the present case.[7] However, we believe that blood-counts are mostly of *negative* value in the differential diagnosis of Hodgkin's disease—that is to say, as helping to exclude leukæmic and certain other infections.

(4) *Lymphogranulomatous Infiltration of Epidural Fat.*—The cases of lymphogranulomatosis maligna in which lymphogranulomatous infiltration of the epidural fat was observed have been collected and discussed by F. Parkes Weber in the *Quarterly Journal of Medicine* (Oxford) and later on again in *International Clinics* (Philadelphia). In Parkes Weber's original case (a young man who had long been under observation with typical Hodgkin's disease in the lymphatic glands of the neck) paraplegic symptoms occurred at the end, and a post-mortem examination revealed the presence of lymphogranulomatous infiltration of the epidural fat. In some cases (though not in the present one) the infiltration of the epidural fat has been associated with a remarkable symmetrical lympho-granulomatous infiltration of the periosteum in front of (ventral to) the vertebral centra, and this association should always be looked for. The reason why the motor or sensory symptoms due to lymphogranu-lomatous infiltration of the epidural fat in cases of lymphogranulomatosis maligna may occasionally be remittent, or pass off (compare certain cases reported from the London Hospital at the annual meeting of the Association of Physicians in 1926), is perhaps to be sought in variations in the turgescence of lymphogranulomatous parts (for instance, as some-times seen in cervical lymphatic glands), which may occur independently of any local X ray treatment. In the present case the patient's extreme general wasting and cachexia may have caused diminished turgescence of the "growth."[8]

If the central nervous sytem and the epidural spinal space were examined systematically in every necropsy on a case of lymphogranulomatosis maligna, even when no nervous symptoms had been recorded during life, lymphogranulomatous infiltration of the epidural fat would doubtless be more frequently discovered than it hitherto has been.

COMPRESSION PARAPLEGIA IN LYMPHADENOMA.

BY C. F. T. EAST, M.D. OXF., F.R.C.P. LOND.,
JUNIOR PHYSICIAN, KING'S COLLEGE HOSPITAL; PHYSICIAN, WOOLWICH WAR MEMORIAL HOSPITAL;
AND
R. C. LIGHTWOOD, M.D., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, PRINCESS LOUISE HOSPITAL FOR CHILDREN.

THE late Sir William Osler,[1] in discussing the ætiology of slow compression of the spinal cord, mentions Hodgkin's disease among its causes, and H. Thursfield[2] says that paraplegia from pressure on the spinal cord is known to occur in lymphadenoma. Nevertheless, published cases of paraplegia from lymphadenoma are infrequent, and this fact warrants a description of the following case.

History.

The patient, a surveyor, became ill at the age of 43. Night sweats commenced in August, 1925, nearly a year

before death. Six months before death "pain in the back and weakness of the legs" was his complaint, and at this time he temporarily lost the use of the legs and arms.

On examination the heart was found to be dilated, the spleen palpable, and the liver enlarged; the urine was normal; a white blood-count gave 4800 leucocytes per c.mm. Careful examination of the nervous system showed no abnormality. During the next month paralysis of the muscles of both upper arms set in, and examination of the nervous system on Jan. 26th, 1926, showed: Cranial nerves, normal. Arms: right deltoid (C. 4, 5, 6), paralysed; right trapezius (C. 2, 3, 4), weak; right triceps (C. 6, 7, 8), weak; right infra-spinatus (C. 4, 5, 6) and supra-spinatus (C. 4, 5) active. All the muscles of the left arm appeared to act normally, but the deep reflexes were absent in both arms. Sensory examination of the arms revealed no objective changes, but there was a complaint of pain in the region of the left scapula and in the back of the neck. Legs: the knee-jerks were weak, the ankle-jerks just obtainable, and the plantar responses were both flexor. Sensory system of the trunk and legs normal. No abdominal reflexes could be obtained. The spleen and liver were still enlarged.

A few days later the right biceps (C. 5, 6) failed, and lymphatic glands became palpable in the left anterior triangle of the neck. A blood-count, dated Feb. 19th, 1926, showed: red cells, 5,520,000 per c.mm.; hæmoglobin, 98 per cent.; leucocytes, 4500 per c.mm. No differential count was done at this time.

By Feb. 23rd, 1926, the liver was slightly, and the spleen markedly, enlarged. Examination of nervous system showed: Optic discs and cranial nerves normal, pupils irregular in shape, no sensory loss, paralysis and wasting of the right deltoid (C. 4, 5), right supra-spinatus (C. 4, 5) and infra-spinatus (C. 4, 5, 6). The right biceps (C. 5, 6) was feeble. The left deltoid (C. 4, 5, 6) and left biceps (C. 5, 6) were paralysed but not wasted. There were no deep reflexes in the upper arms. The ankle-jerks were absent, the knee-jerks just present, and the plantar responses flexor. The cerebro-spinal fluid was slightly straw-coloured, contained six cells per c.mm., showed spontaneous coagulation, and had an albumin content of 0·3 per cent. (normal = 0·04 per cent.). Sir James Purves-Stewart, who examined the case, said that these findings suggested a deposit pressing on the anterior roots of the fifth cervical segment, beginning on the right and extending to the left. The blood at this time showed a commencing anæmia of indefinite character: red cells, 4,500,000 per c.mm.; hæmoglobin, 85 per cent.; colour-index, 0·9; white cells, 7500 per c.mm. The corpuscles were of normal types. A differential count gave: neutrophils, 59 per cent.; lymphocytes, 33 per cent.; hyalines, 7 per cent.; eosinophils, 1 per cent.; basophils, 0.

Subsequently the glands in the left side of the neck continued to enlarge. By April there was weakness of the muscles of the neck, and glands were palpable in both axillæ. In May it was found that there was numbness from the level of the distribution of the tenth dorsal nerve downwards. Retention of urine necessitated catheterisation. During this time the general condition was deteriorating, and the legs gradually became completely paralysed, with absence of knee- and ankle-jerks, and a double extensor response. Sensory loss came on gradually from the level of the tenth dorsal root distribution downwards. An extensive bed-sore appeared on the sacrum and extended rapidly. He died with broncho-pneumonia in July, 1926; the duration of his illness was about 11 months.

Post-mortem Examination.

Autopsy on the day following his death confirmed the diagnosis of lymphadenoma with multiple deposits in the spinal canal. The axillary, cervical, tracheo-bronchial, aortic, mesenteric, and inguinal glands showed lymphadenomatous enlargement, which was confirmed by the microscope in the case of the axillary and bronchial glands. There were also enlarged glands in the portal fissure. An old healed tuberculous gland was found in the mesentery. There was terminal acute pericarditis, pneumonia, and nephritis. The liver was greatly enlarged, weighing 5 lb. 12 oz., and it exhibited fatty degeneration and a number of whitish, fairly well-defined areas of lymphadenomatous deposit. The spleen weighed 1 lb. 12½ oz., and showed similar areas. Sections of liver and spleen showed typical lymphadenoma.

There was lymphadenomatous infiltration of the back muscles (confirmed by microscope) under the trapezius, which had spread into the spinal canal at two levels, apparently by way of the intervertebral foramina, which were filled with deposit, the bones themselves not being invaded. The levels at which invasion of the spinal canal had occurred were (1) at the sixth and seventh dorsal spines, and (2) at the first and second dorsal spines. A mass of pinkish-purple tissue, about 2 inches long, lay on both sides of the seventh dorsal spine. A similar but larger mass lay about the lower cervical and first dorsal vertebræ on both sides, invading the muscle-tissue and extending 2 inches from the mid-line into the muscle on the left side. The deposits in the spinal canal did not penetrate the membranes of the spinal cord, but formed purplish, grey, rather translucent masses lying inside the canal on its anterior wall, adherent to the dura, and extending upwards and downwards from the points of entry. In this manner there was compression of the spinal cord and probably also of the spinal nerves. There were no deposits in the bodies of the vertebræ, as are sometimes found.

Discussion.

F. Parkes Weber has recently summarised the published cases of paraplegia in Hodgkin's disease,[3] and has himself fully described a case, giving details of the post-mortem examination.[4] Certain points seem worthy of further discussion.

1. Although compression of the spinal cord or of the cauda equina is the usual explanation of paraplegia in cases of lymphadenoma, this is not always so, as the following case, described by G. A. Allan and J. W. S. Blacklock,[5] illustrates:—

> The patient, a woman of 44, died of Hodgkin's disease with paraplegia, bed-sores, and septic meningitis. Post mortem no lymphadenomatous deposits were found in connexion with the spinal cord. There was incomplete degeneration of the crossed pyramidal tracts above the mid-dorsal region; below that level there was myelitis with complete degeneration of the pyramidal tracts.

Parkes Weber has suggested as an explanation for these cases of involvement of the spinal cord not due to compression that deep Rontgen ray treatment may give rise to transverse degenerative changes in the spinal cord. Allan and Blacklock's case does not support this suggestion, but other cases might have this explanation. Thus J. A. Ryle supplied Parkes Weber with notes of a case of Hodgkin's disease treated with deep Rontgen ray therapy. This patient quite suddenly lost all power in his lower limbs, and later died with paraplegia. Post mortem there was nothing exerting pressure on the spinal cord, but at the level suspected there was simple softening of the cord over an area of two or three inches.

2. In our case described above the lymphadenomatous deposit appeared to grow into the spinal canal by a process of invasion through the intervertebral foramina. Exactly the same was noted by H. L. Tidy in a case of Hodgkin's disease with paraplegia. The necropsy notes written by J. Bamforth state that "... growths were present in the spinal canal on the posterior aspect of the cord extending from the sixth to the tenth dorsal vertebræ. Four processes were present on each side of this mass and were due to the fact that the growth had made its way into the canal through the spinal foramina. With increase in size, fusion between the various portions of growth from different points of entry had evidently taken place."[6] It was also noted that there were small nodules of growth in the erector spinæ in the lower dorsal region, and at the post mortem lymphadenomatous infiltration of the back muscles (erector spinæ) near the points of entry into the spinal canal was noted. Such findings do not seem to have been recorded in any other cases. The finding of lymphadenomatous deposits in muscle is by no means common.

3. Parkes Weber in his summary refers to 13 cases of paraplegia complicating lymphadenoma, and mentions also one case of Hodgkin's disease with upper limb involvement. The present case illustrates involvement of both upper and lower limbs. Analysis of all these cases (of paraplegia) gives the following summary of the various pathological findings in paraplegia associated with lymphadenoma:—

(*a*) *Lesion due to compression of the cord.*—(1) Deposit in the epidural tissue pressing on the spinal cord or on spinal nerve roots (five cases). (2) Erosion of the bodies of vertebræ by lymphadenomatous growth (two cases). (3) Invasion through intervertebral foramina (two cases). (4) Deposit in the spinal dura mater (one case, and one in which the diagnosis is doubtful).

(*b*) *Disease of the spinal cord other than compression.*—(1) Myelitis (two cases). (2) Syringomyelia (one case).

4. Invasion of the nervous system in Hodgkin's disease is perhaps not so rare as is usually supposed. Thus in a series of 36 patients with this disease observed at Montefiore Hospital during the years 1914–25, ten patients showed invasion of the nervous system.[7] The cases in this series could not be included in the foregoing analysis of pathological findings because in many of them no autopsies were performed, and in the others the details are insufficient.

Our thanks are due to Sir James Purves-Stewart, Dr. A. E. Barnes, and Mr. C. T. Neve for permission to make use of their clinical notes on this case.

A CASE OF TRANSIENT PARAPLEGIA IN HODGKIN'S DISEASE.

BY DEVEREUX FORREST, M.D. DURH., M.R.C.P. LOND.,
MEDICAL FIRST ASSISTANT, LONDON HOSPITAL.

THE literature on this subject is scanty. F. Parkes Weber [1] states there are very few definite cases of this complication on record. He records one case in which post mortem revealed lymphogranulomatous thickening of the periosteum of the vertebræ, and quotes six cases from other authors, one of the latter being doubtful. In the addendum to this paper a further four cases are mentioned, one of which (Dr. J. R. Charles's case) developed spastic paresis, which recovered and had not returned up to the date of death four years later. This recovery was due, it is suggested, to X rays and arsenic. There was no autopsy.

A case is also recorded by G. A. Allan and J. W. S. Blacklock [2] where spastic paraplegia with sensory change took place. Shortly before death the woman developed a paresis of the left arm and face, shortly followed by a complete hemiplegia. Post mortem an acute meningitis with purulent infiltration was found, extending down over the base and upper cord. There was no histological evidence of lymphogranulomatous tissue in any section of the central nervous system. These authors consider that the meningitis could only be responsible for the terminal symptoms.

The following case has some interesting features.

History.

The patient was a warehouseman aged 34 years. Since his discharge from the army in 1919 he had suffered from lack of energy, pain in the chest, and cough. About Christmas, 1922, he noticed a small lump in the left supraclavicular fossa; this subsided in a week or two. It reappeared in February, 1923, and afterwards steadily increased in size. The condition was thought to be tuberculous, and he was sent to a sanatorium. After three months there the diagnosis was revised, and he was admitted to the London Hospital under Dr. Robert Hutchison on June 6th, 1923. He then had a mass of matted glands in the left supraclavicular fossa and one solitary gland in the left groin. One of the former was excised, and the condition was found to be Hodgkin's lymphogranuloma. There was no slight secondary anæmia, but no enlargement of either spleen or liver. The mass in the neck subsided under X ray treatment, and he was discharged improved. He was kept under observation as an out-patient in the medical and radiological departments, and was able to continue his work until July, 1925, when he began to have chronic pains in the stomach and left groin. These became worse, and prevented him from walking any but short distances. About Sept. 1st he noticed that his left leg was numb and cold, and that it appeared weaker than the right. He was admitted Sept. 5th.

[1] Quart. Jour. Med., 1923, xvii., 1.
[2] Glasg. Med. Jour., 1925, ciii., 115.

Examination.—He was a pale, wasted man. Several small fairly discrete glands, varying in size from a pea to a thrush's egg, were present in both supraclavicular fossæ, the left axilla, and both groins. The spleen extended two fingers-breadth, and the liver three, below the costal margin.

In the nervous system the abdominal reflexes were absent, whilst the knee-jerks and ankle-jerks were increased and equal. The plantar reflexes were: right, doubtful flexor; left, extensor. There was no sensory change. Motor power was decreased in both legs, especially the left.

Course.—The condition progressed slowly, and on Oct. 6th spasticity was marked in both legs, and there was a bilateral extensor response. Patellar and ankle clonus were also present. Voluntary movement was weaker, the left leg being almost powerless. On Oct 29th the reflexes were less brisk and, though the bilateral extensor response remained, no clonus was elicited. By Nov. 18th the right plantar response was flexor, and the left ankle-jerk was not obtained. A week later both toes were downgoing and the knee- and ankle-jerks were normal. From this time onwards the condition of the patient became progressively worse and he died on Jan. 4th, 1926. No further evidence of paraplegia was found.

The blood counts showed a progressive anæmia, that on Dec. 8th being: red cells, 2,200,000; hæmoglobin, 35 per cent.; colour-index, 0·8; white cells, 8200.

The Wassermann reaction was negative.

The patient had two doses of X rays, on Sept. 28th and Oct. 2nd, and was on arsenic (liq. arsen. hydrochlor. ℥ iii., t.d.s.) up to September and again from Dec. 8th. It would seem, therefore, unlikely that either of these forms of therapy played a part in his recovery from paraplegia.

Post-mortem Findings.

The following is a summary of the findings. Hodgkin's lymphogranuloma of greatly enlarged and matted left lumbar and left iliac lymphatic glands, and glands around cardiac end of stomach, of moderately enlarged right lumbar and iliac, paræsophageal, bronchial, and upper cervical glands, and of slightly enlarged gastrocoronary and left inguinal glands. Hardbake spleen. Lymphogranulomatous nodules numerous in liver and sparse in marrow of right femur. Partial degeneration of dorsal, pyramidal, and peripheral tracts of spinal cord, and pigmentation of cells of anterior horns; œdema and anæmia of brain. Œdema and emphysema of lungs, with collapse of lower posterior borders. Bilateral pleural effusion; ascites; œdema of kidneys, heart, pancreas, intestines, brain, marrow of femur, and ankles. Parenchymatous degeneration of kidneys. Simple atrophy of myocardium. Slight general atheroma of arteries. Fibrous obliteration of lumen of appendix. Marginal hæmorrhoids. Red marrow throughout humerus and lumbar vertebræ, in upper half of femur, and in a few small areas in tibia. Extreme wasting. No lymphogranulomatous infiltration of brain, spinal cord, meninges, or vertebræ.

Microscopical Examination of Spinal Cord.—Sections were taken of the second, sixth, and seventh cervical, first, fifth, and ninth thoracic, second lumbar, and first sacral segments, and were stained with Ehrlich's hæmatoxylin and eosin, with Weigert's iron-hæmatoxylin and van Gieson's mixture, with Weigert's fuchselin and lithium carmine and by the Weigert-Pal method.

In all segments most of the cells of the anterior cornua are pigmented. The neurochromatin usually forms an ill-defined net. Occasional cells are swollen and very feebly stained. Reduction in size of the cells is not obvious. There is no inflammatory infiltration of the meninges or of the substance of the cord. There is a definite loss of myelin in the columns of Goll in the cervical cord and in the central part of the dorsal columns in the thoracic and lumbar cord. This is associated with slight gliosis and a few fat-granule cells. In the second cervical segment there is a small patch of slight degeneration in each ventrolateral column opposite the ventral surface of the anterior horns, and a small patch of slight loss of myelin in the left lateral pyramidal tract. In the other segments the sections stained by the Weigert-Pal method show pallor in the periphery of the cord, especially in the dorsal cerebellar and adjacent part of the lateral pyramidal tracts. In the first sacral segment the degeneration of the lateral pyramidal tracts appears to be more definite.

Discussion.

The chief lesion is thus a slight degeneration in the columns of Goll in the cervical cord, and in the central part of the dorsal columns in the remainder of the cord. There is also slight degeneration in the ventrolateral and left lateral pyramidal tracts in the upper cervical region, and in both lateral pyramidal tracts

in the sacral region, and a slight degeneration of the cells of the anterior horns throughout the cord. In character and distribution the lesions do not correspond to those in any of the recognised systemic degenerations of the spinal cord. It is reasonable to suppose that the Hodgkin's disease was directly or indirectly responsible for them.

There are three ways in which theoretically the Hodgkin's disease could cause a degeneration of the kind found in the spinal cord: (1) by liberation of toxins; (2) by pressure of granulomatous tissue upon the vessels supplying the spinal cord; or (3) by causing general anæmia. Of toxins there is no direct evidence. Mechanical ischæmia appears to be excluded by the findings at necropsy; the only spinal arteries likely to have been subjected to pressure by the granuloma were the left lumbar. Of general anæmia there is positive evidence; secondary anæmia was found on examination of the blood as early as June, 1923, and it was found to be very severe in September and December, 1925.

In view of the interesting nature of the case, I investigated the hospital records of lymphogranuloma for the past 20 years. Only four cases were found in which there was definite record of spinal involvement. Of these only one came to autopsy.

This patient, a boy, aged 14, gave a history of ten months' duration. He was readmitted to the London Hospital May 5th, 1911, because of weakness and numbness of his legs. He had very widespread Hodgkin's disease, with spastic paraplegia and some analgesia. His condition became rapidly worse, and he died on May 30th. Post mortem, widespread Hodgkin's disease was found, but there was no sign of it having involved the vertebræ or cord. The paraplegic signs were due to syringomyelia. Cavitation extended upwards from the right side of the upper part of the ninth thoracic segment to the left side of the third segment. The central canal was absent in places.

Of the other three, one, a woman of 36, had in addition to spastic paraplegia at first indefinite analgesia and later complete loss of sensation to heat, cold, and pain up to the seventh dorsal distribution. She died at home shortly after discharge, no change in the signs having been observed meanwhile. Another, a boy, aged 18, showed extensive changes, and the sense of touch was also affected. X ray showed extensive destruction of the upper dorsal and lower cervical vertebræ. The last, a girl of 15, showed gross sensory change up to the sixth dorsal roots and spastic paraplegia.

I am indebted to Prof. H. M. Turnbull and Dr. A. B. Bratton for the whole of the pathological details.

SIX CASES OF

SPONTANEOUS OR FORCEPS DELIVERIES

FOLLOWING PREVIOUS CÆSAREAN SECTIONS.

BY M. SALMOND, M.D. LOND.,

THIRD ASSISTANT, OBSTETRICAL AND GYNÆCOLOGICAL UNIT, ROYAL FREE HOSPITAL, LONDON.

THE following six cases are taken from the records of the Obstetrical and Gynæcological Unit at the Royal Free Hospital. They are interesting because in all of them the uterus stood perfectly the strain of either a spontaneous or forceps delivery after Cæsarean section and in one case after two previous Cæsarean sections. The sutures used in the different cases varied; both chromicised catgut and No. 4 silk apparently produced an adequate uterine scar, even when in one case there was sepsis during the puerperium. It is probable, however, that unabsorbable sutures are to be preferred, owing to the formation of autolysing ferments during involution which destroy catgut.

The Cases Described.

CASE 1.—A woman, aged 27. Her first child was delivered in 1922 by Cæsarean section at term on account of a central placenta prævia. There was a history of one slight attack of hæmorrhage a few weeks previous to admission. She was admitted from the antenatal clinic on account of hæmorrhage, and was not in labour. The presentation was a right occipito-posterior and the head was high but could be pushed into the pelvis. The pelvic measurements were: *A.I. 8, I.C. 10, Ext. C. 7¾, P.I. 3¾. On vaginal examination the pelvis showed slight general contraction and flattening, the promontory being just palpable. Cæsarean section was performed at once. The child was a healthy male weighing 6 lb. 15 oz. The sutures used for the uterus were chromicised and fine catgut. The puerperium was normal and the condition on discharge was satisfactory to both mother and child.

Her second pregnancy took place in 1923, a year later. She had a normal antenatal period. The head was high and did not push into the pelvis. The presentation was left occipito-anterior and Cæsarean section was performed at term. A healthy male child was delivered weighing 7 lb. ½ oz. Hæmorrhage was rather profuse. The sutures used were No. 4 silk and fine catgut. The puerperium was febrile. The condition on discharge was satisfactory to both.

The third pregnancy took place in 1927. The antenatal period was normal. Labour occurred at term, and was spontaneous and very rapid. The presentation was right occipito-anterior, the head pushing easily into the pelvis. The first stage lasted 7 hours, the second 45 minutes, and the third 15 minutes. The child was a healthy male weighing 8 lb. 1 oz. There were no complications beyond a second degree laceration of the perineum. The puerperium was normal and the condition on discharge satisfactory to both.

This case is interesting in that it now seems probable that the second Cæsarean section was performed unnecessarily and that the patient would have delivered herself naturally. Chromicised catgut and silk sutures were used and both seem to have been entirely satisfactory in producing healthy scars in the uterine wall.

CASE 2, that of a 2-para, aged 32, is somewhat similar. Her first child was delivered in 1923 by Cæsarean section for central placenta prævia. Pelvic measurements were *A.I. 8¾, I.C. 10½, Ext. C. 7½, P.I. 3½. The pelvic walls were rather easily felt. The child was a male weighing 6 lb. 6 oz., slightly premature. It survived only 24 hours. The puerperium was febrile, partly due to a coliform urinary infection, and partly to sepsis, uterine drainage being poor. The uterus was cleared of clots manually 20 days following the Cæsarean section. After this the patient made an uninterrupted recovery. The sutures used in this case for the uterine wall were No. 4 silk and fine catgut.

Her second pregnancy was at term in 1926. She was normal in the antenatal period. The presentation was right occipito-anterior. Delivery was effected by forceps in order to avoid the risk of rupturing the uterus owing to delay in the second stage accompanied by severe pains. There were no complications beyond a vaginal laceration. Labour lasted 11 hours (first stage 8½ hours, second stage 2 hours, third stage 30 minutes). The child was a healthy male weighing 6 lb. 8 oz. The puerperium and condition on discharge were satisfactory to both mother and child.

CASE 3.—A woman, aged 23, was admitted at term in labour with her first child in 1922. The pelvic measurements were: *A.I. 8½, I.C. 10, Ext. C. 7½, P.I. 4. On vaginal examination the promontory was not felt and the pelvis was of the small round type. The presentation was a footling breech. The membranes were ruptured. One hour later the umbilical cord prolapsed. Cæsarean section was performed at once. A male child, healthy, and weighing 4 lb. 15 oz., was delivered. The hæmorrhage was rather profuse. The sutures used were chromicised and fine catgut. The puerperium was normal and the condition on discharge was satisfactory to both mother and child.

The second pregnancy was in 1924 at term. The antenatal period was normal. The presentation was a right occipito-posterior. After rupture of the membranes had taken place manual rotation was performed and the child was delivered spontaneously as right occipito-anterior. The child was a healthy female weighing 6 lb. 2½ oz. There were no complications excepting a vaginal laceration. Labour lasted 17½ hours (first stage 12½ hours, second stage 4 hours 15 minutes, third stage 45 minutes). The puerperium was normal and the condition on discharge satisfactory to both

* A.I. = Anterior interspinous diameter.
P.I. = Posterior interspinous diameter.
Ext. C. = External conjugate diameter.
I.C. = Intercristal diameter

The third pregnancy took place in 1927 at term. The antenatal period and labour were normal. Delivery was spontaneous as a persistent left occipito-posterior. The child was a healthy female weighing 4 lb. 12 oz. Labour lasted 20¼ hours (first stage 19 hours, second stage 55 minutes, third stage 20 minutes). The puerperium was normal and both mother and child were discharged well.

CASE 4.—The patient, aged 32, had had three normal labours at term and one miscarriage. Her fourth pregnancy was normal. The pelvic measurements were: *A.I. 7, I.C. 9, Ext. C. 7½, P.I. 4, the pelvis being slightly small. The promontory was not felt. She was first attended during her fourth labour on the district but was admitted into hospital having been in labour for 20½ hours with obstruction due to a brow presentation. A retraction ring was present and extended nearly up to the umbilicus and the lower uterine segment was much thinned. Her general condition was good and her pulse 100. Cæsarean section was performed at once. The sutures used were chromicised and fine catgut. The child was a female weighing 9 lb. 1 oz., probably about three weeks postmature. The puerperium was febrile for one week and was complicated by bronchitis. On discharge the uterus was normal and the abdominal scar well healed. The infant was satisfactory.

Her next labour was in 1925, right occipito-anterior, spontaneous, and at term. The child was a female weighing 8 lb. 7½ oz. The first stage lasted 8 hours, the second 27 minutes, and the third 10 minutes. The puerperium was afebrile and uneventful except for slow involution of the uterus. On discharge the uterus was still slightly bulky but both mother and child were satisfactory. She is now in hospital having had a second normal delivery at term following the Cæsarean section. The presentation was a right occipito-anterior. The first stage lasted 7 hours 15 minutes, the second 20 minutes, and the third 40 minutes. The child was a stillborn male. Post-mortem examination showed a tentorial laceration. The reason for the stillbirth is difficult to find as delivery was normal in every way. Her condition during the puerperium is so far satisfactory.

CASE 5.—This patient was 22 years old. Her first pregnancy was in 1920. Her pelvic measurements were: *A.I. 8½, I.C. 9½, Ext. C. 8. She was delivered at term by Cæsarean section because of multiple granulomata of the vulva due to syphilis. The abdominal wound became septic and healed slowly. This operation was not performed at the Royal Free Hospital and there is no record of the suture material used. She attended the Royal Free Hospital for her second pregnancy in 1923. She was found to have a positive Wassermann reaction, and an ulcer on the right labium and had appropriate treatment during the antenatal period. She was allowed to go into labour and forceps were applied during the second stage for fear of rupture of the previous Cæsarean scar. The presentation was a right occipito-posterior. The first stage lasted 18¾ hours, the second 45 minutes, and the third 25 minutes. The child was a stillborn male, and post-mortem examination showed that death was probably caused by tentorial lacerations and cerebral hæmorrhage due to stress of delivery. The puerperium was febrile and complicated by an acute ulcerative condition of the left tonsil, which after various pathological investigations was thought to be syphilitic. The condition of the uterus was satisfactory on discharge.

CASE 6, that of a patient, aged 19, comes under a different category. In 1922 she had her first pregnancy terminated at 38 weeks by Cæsarean section for eclampsia. She was admitted unconscious, having had 12 fits before admission. The sutures used were chromicised and fine catgut. The child died in a few hours. The mother had no further fits after delivery and gradually improved. She was discharged with a trace of albumin and a blood pressure of 130 mm. Hg. The uterus was normal. Two years later she again became pregnant. She was admitted for observation and treatment for albuminuria on three occasions. At 33 weeks she was admitted with eclamptic fits, her blood pressure being 210. The urine was solid with albumin and she had six fits in the space of one and a half hours; these ceased after venesection. Consciousness was regained nine hours after the last fit. Induction of labour was unsuccessfully attempted by means of a Barnes bag. Four days later a stomach-tube was inserted and delivery was effected by means of forceps two days later. During the interval between induction and delivery she had severe headache and blurred vision. She was given potassium bromide, syrup of chloral, and scopolamine during labour. Two hours after delivery she had one fit and regained consciousness six hours later. The child was a male weighing 3 lb. 2 oz. and survived 14 hours. It was examined post mortem and edema of the brain was found and a slight extra epicranial hemorrhage over the right parietal bone. The puerperium was slightly febrile. There were severe retinal hæmorrhages and much exudation on examination of the fundi oculi. On discharge the patient was improving but had some albuminuria still and a blood pressure of 170. The uterus was normal.

In spite of advice the patient again became pregnant. Induction of abortion was performed when her menstrual period was 14 days overdue, and later sterilisation was carried out by means of X rays. The blood pressure was 170/140. It seems probable that in view of the recent statistics on the treatment of eclampsia that Cæsarean section should not have been performed in the ordinary course of events on this patient.

Comment.

It would be interesting if others would collect further cases such as these, and much valuable information might be gleaned from them which would prove helpful in the treatment of future cases, especially those with contracted pelves.

In the treatment of contracted pelvis there is the temptation to rely upon Cæsarean section as an easy method of delivery. A considerable number of cases would undoubtedly deliver themselves if the operation were postponed until the effects of labour had been tested. Even in some cases where the prognosis seemed hopeless for any other method of treatment than Cæsarean section, the results are excellent when the patient has been allowed to attempt spontaneous delivery. It is the practice now in the Obstetrical Unit in some cases to perform Cæsarean section after the patient has been given a trial labour in cases of disproportion and pelvic contraction. The result of this has been a marked diminution in the number of operation cases. The operation is that of the vertical incision high up in the uterus. The uterine incision is now being closed in some cases with four layers of silk sutures—one interrupted layer through the wall avoiding the decidua and peritoneum, one continuous layer between these sutures, one continuous peritoneal layer, and one fine continuous suture to bury the incision entirely. This method of suturing has proved itself so satisfactory that in some cases where a subsequent Cæsarean section operation was necessary the scar on the uterus could not be located.

I am indebted to Prof. Louise McIlroy for permission to publish these cases.

THE PATHOLOGY OF SEA-SICKNESS.

BY G. H. ORIEL, M.D. CAMB.,
LATE SURGEON, CANADIAN PACIFIC STEAMSHIPS.

SEA-SICKNESS, although an ancient malady, still offers scope for investigations as to its pathology and treatment. The modern traveller expects more than sympathy from his medical attendant at sea. The following suggestions have been put forward to explain the cause of sea-sickness:—

(*a*) The *labyrinthine theory*[1,2] suggests that upset in balance occasioned by the instability of the ship causes vomiting, just as does revolving in a chair on land. This theory was tested by the writer in a series of patients in two ways: (1) nystagmus was sought in a series of over 5000 patients suffering from sea-sickness, but was not found; (2) the "revolving" test was performed on a patient in port, 20 revolutions being sufficient to cause nystagmus; the same number were found necessary to cause the same condition when nausea was experienced at sea. A further observation has been recorded that in the case of three deaf mutes who happened to be travelling together, one was sick and two were not.[3] It appears, therefore, that the supporters of this theory should bring forward more evidence to support their view.

(*b*) The *neurotic theory* postulates that the symptoms are the result of auto-suggestion. It will be shown later that there is a metabolic change present, and a theory will be suggested that may explain the fact that some people are sick even whilst the ship is still in port. There are many other suggestions, such as

over-feeding, over-drinking, and constipation, which, although possibly contributory, are certainly not the main factor.

(*c*) It has been suggested that sea-sickness is an acidosis,[4] and is curable by the administration of glucose. It was to investigate this theory that the following work was undertaken; to determine whether the acidosis, if present, were the sequel to, or the main cause of, the vomiting.

The Present Investigation.

A subject for investigation was taken who was normal in every way—a male aged 30. His blood was analysed and found to have a normal content of urea, blood-sugar, chlorides, and uric acid. Hourly specimens of urine were then taken and analysed for free acid and ammonia-content. Folin's method was used throughout—i.e., titrating 10 c.cm. of urine against N/10NaOH, and retitrating after the addition of neutral formalin, using neutral red as an indicator. A three days' average was obtained, the subject being kept on a normal diet, the hours of rising, feeding, and sleeping being the same as those at sea. The pH value of the urine was obtained by the capillator method, using methyl red and bromothymol blue as indicators. Acetone was tested for by the sodium nitroprusside method (Table I.).

TABLE I.—*Showing the Normal for the Subject under Investigation.*

	B.					L.						D.				

TABLE II.—*At Sea at the Commencement of a Storm. Same Methods used as in Table I.*

Per cent. total acidity	84	62	40	32	20	26	30	—	26	22	—	20	—	32	—	64
Mg. of NH_3 (per cent.)	129·2	102	85	51	30·6	34	34	—	40	68	—	27·2	—	34	—	136
pH	5·3	5·3	5·3	6	6·6	6·4	6·2	—	5·6	5·2	—	6·2	—	6·1	—	5·6
Acetone	—	—	+	—	—	—	—	—	—	+	—	—	—	—	—	+
Nausea	—	+	+	—	—	—	—	—	—	+	—	—	—	—	—	+
	B.					L.						D.				

B, breakfast; L, lunch; D, dinner.

The same methods were used whilst at sea at the commencement of a storm. The departure from port took place during the night (Table II.). As the subject for investigation had been kept on the same diet as previously, it is fair to compare the figures in Tables I. and II. During the day the results shown in Table II. were obtained, nausea was experienced as shown in the table, but no vomiting, and the usual food was taken. It will be seen that the percentage of ammonia is much higher, all day, when the ship was pitching, especially when nausea was experienced. Thus:

TABLE III.

	8 A.M.	10 A.M.	5 P.M.	11 P.M.
In port	88·4	34	44·2	70
At sea	129	85	68	136

At these times acetone was also present. It is clear that a condition of acidosis is present *before* vomiting commences. This was confirmed in other cases in which there was no opportunity of obtaining hourly specimens and of studying the cases in detail, but in which samples of urine were obtained during the pre-vomiting stage. Tables IV. and V. illustrate the results.

TABLE IV.—*Showing Acidosis before Vomiting.*

	10 A.M.	5 P.M.
Total acid (per cent.)	14	38
Mg. of NH_3 (per cent.)	17	78
pH	6·9	5·6
Acetone	—	+

Patient vomited at 5.30 P.M.

TABLE V.—*Also shows Acidosis before Vomiting.*

	10 A.M.		10 A.M.
Total acid (per cent.)	44	pH	5·4
Mg. of NH_3 (per cent.)	136	Acetone	+

Patient vomited at 10.30 A.M.

These two cases are typical of the results found on examining the urine in the pre-vomiting state. Once vomiting is established the acidosis becomes much more marked, as there is an added starvation-acidosis present. In bad cases of sea-sickness very high ammonia figures were obtained, as, for instance, in the case shown in Table VI.

TABLE VI.—*Shows Acidosis following Vomiting.*

	7 A.M.	11 A.M.
Total acidity	38	100
Mg. of NH_3 (per cent.)	173	265
pH	6·7	5·4
Acetone	+++	+++
Diacetic acid	+	++

It is difficult to say how much acidosis is due to starvation in such a case, but it is as severe as that found in diabetic coma. A patient in a condition of acidosis following sea-sickness is semi-unconscious and dyspnœic, with a very feeble pulse. It must be by a deepening of this coma that deaths from sea-sickness occur, although I was fortunately unable to investigate such a case owing to lack of opportunity.

The fact that acidosis was found in the pre-vomiting stage suggested that the blood-sugar might show alteration in this stage, and this matter was investigated. It will be appreciated that blood-sugar estimations are not easily carried out during storms at sea, but every care was exercised to obtain accurate results. Folin and Wu's colorimetric method was used throughout. Table VII. shows the blood-sugar of the same person from whom Tables I. and II. were compiled, while he was suffering from the premonitory symptoms.

TABLE VII.

—	A.M.		P.M.			
	9	11	1	4	6	8
Blood-sugar	0·09	0·11	0·15	0·07	0·065	0·
Acetone	—	—	—	+	+	-
Nausea	—	—	—	+	+	-
Total acid (per cent.)	44	22	30	24	32	6
Mg. of NH_3 (per cent.)	68	30·6	38	68	64	13
Urine sugar	—	—	—	—	—	-
	B.		L.		D.	

B, breakfast; L, lunch; D, dinner.

It will be seen that there is a preliminary hyperglycæmia followed by a hypoglycæmia, accompanied by acetonuria and increase of ammonia excretion. The hyperglycæmia is not very marked, 0·16 be

the highest that was found, except in the case of diabetics; also, sugar was not detected in any urines tested in cases of incipient sea-sickness, but a rise in blood-sugar was constantly found. Estimations of blood-sugar were also made in the case of persons in whom sickness was firmly established. In these cases the blood-sugar was found to be uniformly low, although it might be argued that this was the result of starvation.

Glucose was given in doses of 3 drachms (gr. clxxx.) to more than 1000 patients with sea-sickness, and the following results were noted. The effect observed in well-established cases was much superior to that obtained by the exhibition of other remedies such as atropine and strychnine, belladonna, chloral, bromides,[5] alkalis, and the various patent remedies. When glucose is administered to a well-established case acetone disappears from the urine, diuresis takes place, and ammonia excretion is lowered, with a corresponding increase in total acidity in the urine. Pari passu with the metabolic change there is an improvement in the general condition, and headache is abolished. The occurrence of diuresis is interesting and similar in nature to that which occurs after the other acidoses such as post-anæsthetic vomiting and cyclic vomiting.[6] The effect of giving glucose is also good in the pre-vomiting stage, and here again acetone is abolished. It is an undoubted fact, however, that glucose administered to a well-established case is much more dramatic in its effect than in the pre-vomiting stage. Table VIII. shows a severe case treated with glucose in doses of 3 drachms:—

TABLE VIII.

—			Glucose 3iii.	
	7 A.M.	11 A.M.	2 P.M.	9 A.M
Total acid (per cent.) ..	40	100	96	100
Mg. of NH_3 (per cent.) ..	176·8	265·2	212·2	136
Acetone	++	++	+	—
Vomiting..	++	++	++	—
Blood-sugar	0·074	0·08	0·10	0·09

If the vomiting is severe and glucose cannot be retained for 15 minutes (in which time a large portion is absorbed) it has been given with success both intravenously and rectally. Table IX. shows a pre-vomiting case treated with glucose. No vomiting had taken place nor did it subsequently occur.

TABLE IX.

—		Glucose 3iii.	
	10 A.M.	5 P.M.	10 P.M.
Total acidity	14·0	38	56
Mg. of NH_3 (per cent.)..	17	78·2	68
Acetone	+	+	—
Nausea	+	+	—

Comment.

Experiments show therefore: (*a*) That labyrinthine disturbances, if present, do not give rise to nystagmus or to alteration in labyrinthine tests.

(*b*) That auto-suggestion is not wholly responsible, but there is a distinct metabolic upset found in the pre-vomiting stage, as shown by (1) hyperglycæmia followed by hypoglycæmia; (2) increased ammonia excretion; and (3) the presence of acetone in the urine.

(*c*) That when vomiting is established there is a very severe acidosis, as indicated by excretion of ammonia up to 265 mg. per cent., and the presence of much acetone and diacetic acid in the urine.

(*d*) That the administration of glucose causes diuresis, abolition of acetonuria, and a fall in the ammonia excretion, resulting clinically in the relief of symptoms.

It is often found that diabetics show a much higher blood-sugar content when worried, and it has been repeatedly shown that in normal persons the blood-sugar may be raised even beyond the renal leak-point by emotional disturbance. It is reasonable to suppose that the combination of worry of departure, new surroundings, and stimuli to the sympathetic system by the motion of the boat cause an initial rise of blood-sugar. The succeeding fall is presumably due to exhaustion of glycogen reserve. One finds that if passengers can be persuaded to eat plenty of fruit and carbohydrates and to avoid fats, that they are never violently sick. The common error is to avoid food, which, of course, leads to early exhaustion of the glycogen reserve. Acidosis is the inevitable sequel. Once this train of events is in progress other factors, such as inability to take food and constant vomiting, tend to make the acidosis more severe. The administration of glucose reduces the acidosis by oxidation of the ketones and allows food to be taken normally.

It has occurred to me that it would be advisable to administer small doses of insulin with a large dose of glucose to those cases which are not cured by the administration of glucose alone, in the same way that this procedure has been adopted with success in hyperemesis of pregnancy by V. J. Harding, of Toronto. I have not tried this, hoping that others more experienced in the method will advise me as to its feasibility.

My thanks are due to the Canadian Pacific Steamships for facilitating this work, and to Prof. E. C. Dodds and Dr. A. A. Osman for their kindly interest and invaluable criticism.

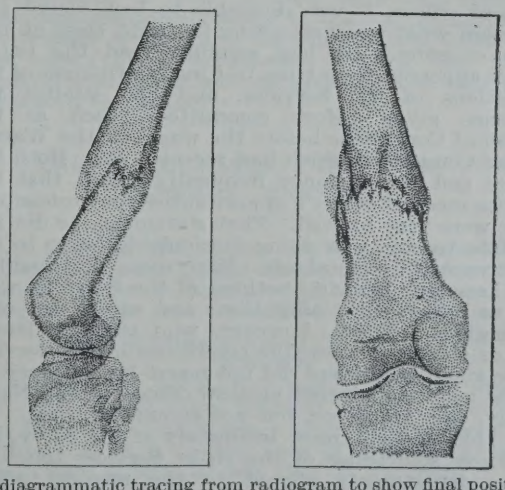
THE USE OF LISTON'S LONG SPLINT

IN THE TREATMENT OF FRACTURE OF THE FEMUR.

BY ROBERT MARTIN, L.R.C.P. EDIN.

LISTON'S long splint, which was so much used in my early days in the treatment of fracture of the femur, appears to be going out of fashion. Possibly its successors are better in themselves, but do they



Semidiagrammatic tracing from radiogram to show final position of the fragments.

give better results and more comfort to the patient? I have treated two cases of fracture of the femur with this splint—namely, a case of simple fracture of the lower third with absolutely no shortening

and perfect movement, and the case which is here illustrated.

The patient, a man of 28 years of age, was run over by a horse and cart and the "cockers" of the horse's shoe went into his leg, one over the knee-joint and the other a few inches up the thigh. The result was a compound fracture of the lower third of the femur implicating the knee-joint, and as the accident occurred in the winter time on dirty roads, and it was absolutely impossible to thoroughly cleanse and disinfect the wounds, I put the limb up, in a Liston's splint, in the usual way. On account of the septic condition of the wounds suppuration set in around the knee and the calf of the leg and I had to take it down daily for over two weeks to cleanse and dress the wounds. This was all done in a house of two rooms and a kitchen and with no trained assistance; the only help I had was from the patient's father and mother and some of the neighbours. There is absolutely no shortening, and many a time the patient has said, "No one knows that I had a broken thigh." He has followed his avocation as manager of a mill for years without any discomfort whatever.

Banbridge, Co. Down.

Corrigendum.—In the paragraph of Sir William Willcox's lecture on the treatment of pernicious anæmia dealing with the Murphy-Minot diet (THE LANCET, Oct. 8th, p. 778), the daily requirement of liver or kidneys should, of course, be 200 (not 20) grammes. The slip was corrected in part of our issue.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

WAR SECTION.

THE opening meeting of this Section took place on Oct. 10th, when Surgeon Vice-Admiral A. GASKELL delivered his presidential address on

PROFESSIONAL OPPORTUNITIES OF THE SERVICE MEDICAL OFFICER.

He explained that his purpose in choosing this subject was to deal a death-blow to the parrot-cry that there were no, or, at all events, very few and very limited opportunities in the Services for medical officers. To the uninformed it was a plausible statement, and at a time like the present, when the Services were anxious to attract the best type of medical officer, it was desirable to look round and ascertain what was preventing the right class of man from entering. He had carefully read the letters which appeared from time to time in criticism of the conditions of the Services, and had studied the evidence given before committees, such as the Durnford Committee before the war, and the Warren Fisher Committee which had recently sat. Both the letters and the evidence frequently stated that the Service medical officer's opportunities for professional work were very limited. That statement, he did not hesitate to say, was doing incalculable harm to the Services on the medical side. Many men, fully qualified and keen but knowing nothing of the Services, were apt to believe such allegations and so did not offer themselves. Those, however, who through family ties or otherwise knew the conditions of the Services to be good, joined and did not regret having done so. There were magnificent medical officers in the Navy, Army, and Air Force, but not enough of them. He was able to speak most intimately of the Navy, but he knew something of the sister Services too. All three departments offered to the medical officer magnificent opportunities, as was amply shown in the addresses dealing with the subject by the late Sir William Leishman and Group Captain Cooper. The President grouped the professional opportunities under six headings: (1) reading, (2) obtaining higher qualifications, (3) perfecting training in methods of clinical examination, (4) obtaining access to sufficient good clinical material, (5) specialist and laboratory work, (6) the compilation of wealth.

The Six Opportunities.

(1) The great difference between the life of the Service medical man and that of the doctor in civil life was that in most cases the life of the latter was a very monotonous one, the direct contrary of that of his brother in the Services. For two or three years the latter would be doing regimental work, or would be on board ship, and then would have a strenuous three years in a large hospital. The life of the ordinary general practitioner was usually too full of mechanical routine to allow of much reading, research, or the recording of his experience, whereas these things, with plenty of hard work and high-class surgery to satisfy the greatest glutton for work, were included in Services experiences. His own 34 years in the Navy could be taken as a fair sample of what the Services medical officer had in the matter of opportunities, for during that time he had had facilities for taking part in every branch of the profession—except, of course, diseases of women. In addition, the less strenuous periods afforded time for study and for getting up to date in medical and surgical knowledge. The usual run of panel doctor had no such intervals of comparative leisure.

(2) With regard to opportunities of obtaining higher qualifications, in civil life, once the young man was launched into practice, he had neither time nor means for studying for higher examinations, while in the Services men while still on full pay had granted to them periods of study-leave.

(3) He had frequently pondered the perfecting of training in methods of clinical examination. It was of the greatest importance to examine recruits for the Services very thoroughly, for if a man was fit when he entered, it was a comparatively simple matter to keep him so. This necessity trained the medical officer to conduct examinations quickly and reliably, and these should be in the hands of expert and experienced medical officers. Stress was being laid on the importance of periodic medical examinations. That was not possible on a large scale in civil life, though it might be optional in schools and institutions; but in the Services there were ample facilities for appreciating what the vigorous healthy normal was, and that was the finest groundwork for discovering disease.

(4) Some might consider that in a large Service hospital there might be a quantity of clinical material but not quality—i.e., that there was not a sufficient variety. As a fact, those hospitals contained patients of all ages, including those on the retired list, and there was a good deal of major surgery. On the subjects of venereal disease and tropical diseases the material was not only good, but was extensive, and it was doubly useful because of the facility offered for following up the cases, one of the defects which marred complete study in civilian and even ordinary hospital practice being want of this facility.

(5) With regard to specialist and laboratory work he referred to many branches of such activities and reminded the audience that while no medical officer in the Services was allowed to forget that he was first and foremost an all-round medical man special work was now paid for at an increased rate.

(6) The Services medical officer was not highly paid. Periodically, committees dealt with questions of pay and remuneration, and he was convinced that the better the type of medical officer secured for the Services the better, eventually, would be the scale of payment. Moreover, a system of deferred pay enabled the medical officer to draw a pension, perhaps a larger amount than many civilian practitioners were able to save out of their practices. It was true that it was once declared that medicine was a magnificent profession but a very poor trade, but that should not prevent anyone from joining it. Much, of course, depended on the man himself, for the keen man made his opportunities and seized them when they

occurred. He sometimes thought that those who were loudest in their criticisms of the conditions in the Services were those who were not desperately keen on their work; they were probably representative of the spoon-fed, the poseurs.

Discussion.

Sir MATTHEW FELL, R.A.M.C., said that he joined the Services two years before the South African War, and after that war a Commission considered the reorganisation of the whole system. It was due to its findings that cases were concentrated at large hospitals instead of being scattered at many places, and this greatly facilitated study, and resulted in the aggregation of valuable clinical material.

Air Vice-Marshal DAVID MUNRO said there was no need to apologise for lack of clinical or other opportunities in the Services, for in many cases they were more varied than in civil life. When that was fully realised he had no fear for the future of the Services. Some seemed to think that even if the opportunities existed, encouragement was not given to the keen man to pursue his career on his own lines. When it was understood that the policy of the Services was to encourage men to do the work they were keen on, and that advancement was obtained along professional lines, the name of the Services from the medical standpoint would be such that there would no longer be any recruiting difficulty.

Admiral Sir JOSEPH CHAMBERS said that the recent shortage of candidates in the Services was due to misapprehension as to the professional opportunities offered, and the kind of life. It simply needed that the true facts should be known, then the difficulty would have been solved.

Mr. T. B. LAYTON remarked that a very important part of the work in the Services was keeping well and fit large numbers of human beings who entered quite fit physically and mentally. There was no means of obtaining that experience in civil life, but he thought there must be in the future. His four and a half years of war service gave him a good opportunity of judging of the differences of opportunity provided by the two sets of conditions. The mental aspect was also important. Frequently a man came with symptoms, the cause for which was sought in an organic lesion in some small part of the body, and it transpired that it was due to a mental cause. In the war a regiment would show a sudden abnormal incidence of sickness, and it was sometimes traceable to the fact that the men as a whole, for some particular reason, were not happy. The Services also taught the importance of the accurate filling up of documents. In civil life carelessness in this regard often led to serious delay.

The PRESIDENT replied briefly.

MANCHESTER MEDICAL SOCIETY.

A MEETING of this Society was held on Oct. 5th, Dr. J. GRAY CLEGG, the President, in the chair.

Pituitary Tumours.

Dr. GORDON HOLMES delivered an address on Pituitary Tumours, a subject, he said, that offers interest to all branches of the medical profession, to those engaged in academic work as well as to those who meet symptoms of pituitary disease in clinical practice, since recent investigations go to show that many of the functions which have been attributed to the pituitary belong to the nervous structures in the base of the brain, especially in the hypothalamus. At present the only function that can with certainty be ascribed to the anterior lobe of the pituitary is an influence on growth, but it probably also controls the development and activity of the sexual organs. Though extracts of posterior lobe have obvious effects when administered by injection, we are still ignorant of its normal function. The clinical symptoms of pituitary disease can be, however, still most satisfactorily divided into those attributed to an over-function of the gland, or rather of its anterior lobe, and those which result from its destruction or deficient activity. The chief symptoms of hyperpituitarism are acromegaly when the disease commences after adolescence, and gigantism, with which certain features of acromegaly or of hypopituitarism are often associated when it begins before normal growth is completed.

The symptoms of hypopituitarism, Dr. Holmes said, are more common and more varied. Dwarfism, usually associated with under-development of the sexual organs and absence of the secondary sexual characters, results from destructive lesions of the gland before the age of puberty. It is usually due to extrasellar tumours and other conditions that compress the pituitary, for adenomata of the gland are rare at this age. Metaplasic adenomata developing after puberty produce Fröhlich's syndrome, or regression of sexual development and of the secondary sexual characters, disturbances in carbohydrate metabolism, and frequently somnolence and polyuria. In addition to these symptoms, which are usually regarded as a direct result of the pituitary disease, other symptoms due to the pressure of the tumour on neighbouring structures are often present. At first the intrasellar tension, and later the increase of general intracranial pressure, produce headache and occasionally vomiting, while the compression of one hemisphere or of a cerebral peduncle may give rise to a hemiplegia. More characteristic symptoms are due to compression of the visual paths, which produces more or less characteristic defects in the visual fields, the type of which depends on where the pressure acts. When the chiasma is situated posteriorly one optic nerve usually suffers first so that unilateral blindness results; this is usually followed by a temporal hemianopia in the other eye when the tumour extends back to the chiasma. When the chiasma is first involved an irregular bitemporal hemianopia is found, while the loss is mainly of the homonymous hemianopia type when the tumour compresses one optic tract. One early and frequent feature of the visual defects, which is often forgotten, is the occurrence of scotomata, either central, when the optic nerve is compressed, or more commonly paracentral in the temporal fields. The ocular nerves are frequently involved too, causing squint and diplopia.

At present, said the speaker, the most reliable treatment of pituitary tumours is operation, which has become a moderately safe procedure in skilled hands, but good results have been obtained by radiological treatment, and it seems that further development of this method may be expected. Glandular treatment, either to control the growth of the tumour or to relieve the symptoms of deficiency, has rarely given satisfactory results, but recent experimental investigations give promise of greater success in the future.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.

ON Oct. 4th the winter course of lectures at the James Mackenzie Clinical Institute, St. Andrews, was opened by Dr. A. MAITLAND RAMSAY, the honorary director, with an introductory address on the

Ocular Manifestations of Gastro-intestinal Disorder.

It was pointed out that in gastro-intestinal diseases the causal relationship between the general disorder and the ocular symptoms is not nearly so direct and intimate as it is in the case of cerebral, renal, or circulatory affections, but that in an indirect way, through the agency of micro-organisms and of bacterial or biochemical toxins, gastro-intestinal disturbance plays an important part in causing or in aggravating diseases of the eye. Attention was drawn to the reflex disturbances in the eye caused by dental caries or septic tonsils, which were also mentioned

as the cause of acute or of chronic inflammation of the eyeball. That was illustrated by a brief description of toxic or recurrent iritis. A careful distinction was drawn between chronic intestinal auto-infection and chronic intestinal auto-intoxication, and in this connexion reference was made to the work of Desgeorges. Disordered metabolism was regarded as the underlying cause not only of inflammation of the uveal tract, but also of acute glaucoma and of toxic amblyopia, and the influence of persistent constipation on the occurrence of intra-ocular hæmorrhage in young adults was fully discussed. The attention of the general practitioner was directed to the possibility of atrophy of the optic nerve following severe hæmatemesis. The retinal ischæmia was regarded as a favourable condition for the action of a toxin or other infective agent, whose existence may be assumed although it does not admit of strict scientific proof. The lecture concluded with a description of a group of eczematous affections of the eye associated with disordered carbohydrate metabolism, and it was said that in the treatment of these conditions it was necessary to pay special attention to the diet, and also to take means to promote free elimination of the metabolic toxins which have accumulated in the blood.

In the ensuing discussion Dr. W. C. SOUTER gave a short summary from personal experience of the varied gastro-intestinal disorders, functional, organic, and toxic, in which eye phenomena may be met, special emphasis being laid on the help obtainable from an examination of the eyes in cases of unsuspected luetic affections.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society held on Oct. 6th Dr. DONALD HALL gave the presidential address entitled

Some Help Obtained from Electrocardiography

based on the examination in private practice of 419 patients during a period of three and a half years. The word "help," he said, was used advisedly, for this method of examination was of use not in supplanting but in supplementing ordinary clinical methods, often giving useful information which otherwise was lacking. All the information regarding disorders of rhythm was given equally well or better by the electrocardiogram than by the polygraph, and on the myocardium the polygraph was silent. In graphic methods the electrocardiogram had superseded the polygraph in all pathological conditions except pulsus alternans, in which the sphygmograph was the more reliable, although he had obtained records with both instruments.

Dr. Hall quoted a case of a woman of 26 who had assumed an invalid's life as a result of a diagnosis of "heart strain." Finding the cardiac signs and borders normal her present medical attendant had sent her for electrocardiographic examination with a view to deciding the nature of her arrhythmia, which was noticeable to the patient herself. It proved to be a striking example of sinus irregularity; the original diagnosis had been mistaken, and the patient's illness had been the result of suggestion. All her symptoms had now disappeared and she was leading an ordinary active life. Sinus irregularity was the only form of cardiac irregularity which was purely physiological. While premature beats were in many cases of but minor importance, each case had to be considered on its merits. In general terms auricular and junctional premature beats were more often due to extrinsic causes, and in many instances the patient was unaware of their presence, whilst ventricular premature beats were intrinsic in origin and the patient was usually cognisant of them. At times multiple premature ventricular beats might be the main cause of the patient's subjective symptoms, particularly of giddiness and faintness, these symptoms disappearing on restoration of the normal rhythm. Simultaneous photographs of electrocardiogram and pulse tracing demonstrated that although the premature beats gave large complexes in the electrocardiogram they were dynamically but feeble contractions; thus whilst "extrasystole" was a misnomer, the term "dropped beat" was often correct so far as the pulse at the wrist was concerned.

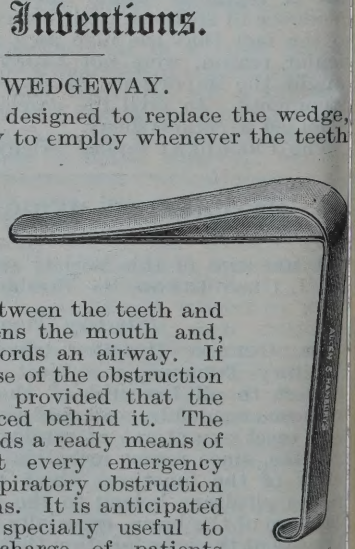
There were many cases, said Dr. Hall, in which alteration in the ventricular complexes had given really important information, sometimes when clinical evidence was but scanty or absent. Within the last few days, for instance, he had seen a man of 65 who, without any premonitory symptoms, had become unconscious while playing cricket with his grandson. A careful clinical examination had revealed no cardiac, vascular, renal, or aural disease, but an electrocardiogram had shown right-bundle-branch block. He had met 16 instances of this condition in his series, the lesion affecting the left division in three and the right in 13 cases. In his 419 cases there had been 35 patients in whom the T-wave was negative in lead I. or lead II. or in both these leads. Three were untraced and of the remainder 16 were alive and 16 dead. This T-negativity he had found relatively frequent in cases of angina pectoris, and examination by the electrocardiograph had proved useful in strengthening the medical attendant's hand in the treatment of refractory patients.

Very puzzling, said Dr. Hall, were the cases in which patients complained of such symptoms as pain, faintness, palpitation, and shortness of breath, yet on examination yielded few or no physical signs. If such a patient was a young woman without mitral stenosis it was safe to assume that her chest pain—which typically was submammary and not retrosternal—was not of cardiac origin. Far more difficult were the same symptoms in middle-aged people, and particularly in middle-aged men. It was often hard to find firm ground for insisting that such patients should limit their activities at a time of life when they were at their business or professional zenith, and their responsibilities were greatest. In such cases help was often obtained from examination of blood pressure and urine, but in a residue he had found that information could be obtained from an electrocardiogram and by no other means.

New Inventions.

THE WEDGEWAY.

THIS instrument is designed to replace the wedge, which it is customary to employ whenever the teeth of an unconscious patient are tightly clenched and respiration is obstructed. It consists of a tongue depressor having a double deck. The thin end is passed between the teeth and when pushed on opens the mouth and, at the same time, affords an airway. If the tongue is the cause of the obstruction it can be depressed, provided that the wedgeway is introduced behind it. The instrument thus affords a ready means of dealing with almost every emergency which arises from respiratory obstruction in unconscious persons. It is anticipated that it will prove specially useful to nurses, who have charge of patients during recovery from anæsthesia, and it has the further advantage that it is inexpensive and cannot get out of order.



The Wedgeway is sold by Messrs Allen and Hanburys, Ltd., 48, Wigmore-street, W.

Reviews and Notices of Books.

THE HEALTH OF THE NATION.

By F. E. FREMANTLE, M.P., M.B., M.Ch., F.R.C.P., F.R.C.S., D.P.H., Consulting County Medical Officer of Health for Hertfordshire; Lieut.-Colonel, R.A.M.C. (T.A.) retd. With a Foreword by the Rt. Hon. NEVILLE CHAMBERLAIN, M.P., Minister of Health. London: Philip Allan and Co., Ltd. 1927. Pp. 209. 8s. 6d.

THE object of this book is explained, though not from exactly similar standpoints, both in an introductory note by the author and a foreword from Mr. Neville Chamberlain, the Minister of Health. That object is to bring together the main factors concerned in the preservation of the health of the people, as they are represented by the central work of the Ministry of Health, and by the various professional, municipal, and local activities which carry on their duties either in direct association with the Ministry or along lines which bring them under the ægis of the Ministry. The administration of public health presents many problems in which the public is acutely interested, but without understanding what are the steps that have been taken by the law of the land to meet the situations; while when the public is aware of the details of administration too often it is ignorant both of the grounds which prompt medical action and of the part which that action plays in the general pattern of what may be termed the statecraft of public health. As the Minister of Health says in the foreword, the history of public health organisation in this country has had strange and varied origins to account for its growth, and that growth, in waxing, has incorporated aspects of human life which had been considered formerly to lie outside its scope. Hence the complicated design of the machinery devised to maintain the health of the nation; hence the difficulty of perceiving how development has taken place and Colonel Fremantle's book is designed to make matters clear.

The plan of the work is simple, as is fitting in a guide-book. The history of public health organisation is outlined in such a way that the complications of administration can be seen to bear relation to the various origins of legislation. We are invited first to consider the size of the population affected, and the main figures of the last census, that of 1921, are employed from which to draw deductions. The deduction which is most pertinent to the sequels is the author's opinion that there is no case for those who would defend the declining birth-rate of this country on the ground of over-population. A chapter on the records of birth, sickness, and death in the country as illustrated by the figures of registration and notification is placed in juxta-position with the census figures, and on the whole makes cheerful reading in its evidence of medical and sanitary progress. In speaking of the National Insurance Acts, of which the author is obviously critical, what is termed the economics of health are introduced to our notice when discussing the amount paid out in sickness and disablement benefit as a useful index to the gross amount of sickness in 13,000,000 insured persons, constituting one-third of the population. These figures, which in general do not include the first three days of illness (for which benefit is not payable), show a total loss in 1925 of 25,000,000 weeks' work, or the equivalent of nearly half a million persons' work throughout the year. This great fraction of the population is made up of individuals all belonging to the industrial classes, and in discussing the economics of health Colonel Fremantle draws up a profit and loss statement of a striking nature in order to show that the improvement of the public health is not only an act of social philanthropy, but also a sound instrument of economic development and insurance against economic loss. This profit and loss statement shows, says the author, "on the debtor side the five items: (1) to loss on patients' work; (2) to lesser efficiency of those at work; (3) to cost of care and treatment; (4) to indirect loss in industry from epidemics; (5) to cost of maintenance of public health services. On the creditor side it would show the profits: (1) by lives saved; (2) by longer life." By rough but fair estimates Colonel Fremantle then deduces the following as the main heads, of the achieved profit from improved health, of the actual cost of public services for maintenance of health, and of the apparent loss from present-day sickness and disablement:—

Annual Profit.

	£
1. By lives saved	77,212,000
2. By longer life	200,000,000
Total	£277,212,000

Annual Loss.

	£
1. To loss on patients' work	80,000,000
2. To lesser efficiency of others	80,000,000
3. (*a*) To care and treatment in institutions	50,000,000
(*b*) To care and treatment at home	24,000,000
4. To loss of work on those in attendance on the sick	10,000,000
5. (*a*) To public health services	43,900,000
(*b*) To school health services	3,200,000
Total	£291,100,000

To the debit side there must still be added the cost of indirect losses from disturbance of industry, so that the annual loss, on these calculations, would amount to £300,000,000. He quotes Prof. Fisher, of Yale, in support of the view, which seems widely held, that one-third of the loss is preventable, and he respectfully commends the conclusions to the consideration of the Treasury, with a qualifying remark which indicates the side of the House of Commons on which he sits.

With the ground thus cleared Colonel Fremantle discusses the duties and responsibilities of health authorities and their officers, the provisions laid down for the securing of pure water and food—especially milk—and adequate light and air for the community; the procedures adopted by public bodies, the medical profession, and private organisations for the abatement of infant mortality; the benefits obtained under school inspection, hospital administration, insurance, and old age pensions. Chapters follow upon the influence of infectious fevers upon the community; upon the efforts to combat "the four scourges," tubercle, cancer, alcoholism, and venereal disease; upon the circumstances in which the victims of mental disease are treated; and upon the provision made for the safety and succour of industrial workers—in which last section we are glad to see a valuable note on the health of the mercantile marine. This category shows that the author has been truly inclusive in the matters which he desires to make clear to the public, and throughout his information is given in a manner that should be of great and practical assistance to the various authorities entrusted with the care of the health of the nation.

DISEASES OF THE HEART.

Their Diagnosis, Prognosis, and Treatment by Modern Methods. Second edition. By FREDERICK W. PRICE, M.D., F.R.S. Edin., Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London. London: Humphrey Milford, Oxford University Press. 1927. Pp. 584. 21s.

Dr. Price's book was welcomed by the practitioner when it first appeared nearly ten years ago as something that was lacking in medical literature—namely, a reasonably complete account of the diagnosis, prognosis, and treatment of heart diseases in the light of recent physiological research and with due regard to the clinical observation of the past. An amazing amount of material was condensed within

the 472 pages, the essential points needed by the practitioner being presented with clearness and literary exactness. The second edition of the book retains the same general form as its predecessor with the addition of some 100 pages of new matter, including chapters on syphilitic heart disease—Dr. Price regards syphilis as the cause of a large proportion of all cases of aortic incompetence—the X ray examination of the heart and aorta, and (in collaboration with Dr. J. Blomfield) anæsthesia in relation to heart affections. It seems that in this country at all events radiologists are but rarely asked to examine heart cases; the author has for some years made it a practice to watch the progress of such cases on the screen and is here recording his own experience. Reference is made to the more recent work on the pathology of auricular fibrillation and quinidine therapy, the possibility of surgical treatment in angina and mitral stenosis, and some of the rarer forms of heart-block. In the older section of the book will be found a classification of cardiac cases for the purpose of prognosis which is eminently practical, and the description of polygraphic records is both lucid and concise.

Condensation has been carried far; the reader will find it difficult to follow a sentence of 14 lines in which the various causes of high blood pressure are enumerated, and will be tempted to wonder if it would not have been simpler to give a complete list of the conditions which are in no way associated with hypertension. Again, the student who has learned the meaning of "normal variation" in the physiological laboratory will hardly accept an unqualified assertion that the arterial blood pressure varies from 170 to 200 mm. in cases of simple hyperpiesis, and from 160 to 220 mm. in secondary contracted kidney. The statement that "the indications of failure of the left auricle are pulmonary in character, while the indications of failure of the right side of the heart are those of tricuspid incompetence" is not in keeping with the up-to-date character of the rest of the book and carries the reader back to the days when all the symptoms of congestive heart failure were attributed to back pressure. It should be borne in mind, however, that the book is a synopsis rather than a critical review of cardiology. On many subjects cardiologists are bound to differ, and a text-book intended to satisfy the needs of students or practitioners must inevitably be dogmatic in tone. Limitations of space make it impossible for the author to quote the evidence on which many conclusions are based, and the student has to rely to a great extent on the author's judgment. In most respects he conforms to orthodox teaching and at times expresses no opinion, leaving the student to form his own.

It is perhaps the inevitable defect of a book of this kind that it should lack clear personality. A supplementary volume containing clinical records of cases would give life to the dry bones of systematic teaching. In one respect we think the arrangement of material might be improved. The chapter on electrocardiography, which now occupies 47 pages, is isolated at the end of the book. A better sense of proportion would be gained by its incorporation in the sections dealing with the various disorders in which it is of clinical value. The production of the book is faultless.

RENAL DISEASE IN CHILDREN.

Clinique Médicale des Enfants: Affections de l'Appareil Urinaire. By Prof. P. NOBÉCOURT. Paris: Masson et Cie. 1927. Pp. 345. Fr.40.

THIS unit of Prof. Nobécourt's well-known series is arranged on the same lines as the earlier volumes which have received notice in our columns from time to time. Each chapter consists of a detailed account of the clinical and biochemical features of an individual patient, followed by a discussion of the disorder that the case exemplifies. From the application of this method to conditions such as nephritis it follows that the author's classification is, in the main, a clinical and biochemical one; comparatively little emphasis is placed on the relative involvement of tubules and glomeruli, while attention is focused on the varying predominance of azotæmia, hypertension, and hydræmia with retention of chlorides. Eclamptic symptoms—the author is in agreement with K. D. Blackfan and others who avoid the word "uræmic"—are attributed almost entirely to hypertension and consequent physical factors. Stress is laid on the comparatively slight and transient effects of azotæmia per se in the nephritis of children compared with adults, though the frequent association of a moderate degree of azotæmia with chloride retention is recognised. The same method is applied to a number of other questions pertaining to renal disease, among them being the relation of non-scarlatinal streptococcal infections of the throat, and of purpura, to nephritis. This volume is as attractive and as full of interest as its predecessors, and provides a lucid presentation of modern views on this branch of children's disease.

PLASTIC SURGERY OF THE HEAD, FACE AND NECK.

By H. LYONS HUNT, M.D., L.R.C.S. Edin. Philadelphia and New York: Lea and Febiger. Pp. 1065. $7.00.

FACIAL surgery has in recent years reached a very high stage of technical development as a result of the need for repairing war injuries. This volume attempts to review the whole subject, and includes a discussion of special methods of anæsthesia and all the numerous devices for transferring skin to the face. The methods described are for the most part well-recognised procedures, but we cannot always agree with the author's judgment in the selections he has made. For example, the only methods described in detail for the treatment of cleft palate are those of Lane and Brophy which, in this country at least, have been entirely abandoned in favour of the simpler operations of Langenbeck and Berry. The book contains many indications of the country of its origin, from the use of "turtle bile" in the treatment of keloids to the final suggestion that the ordinary hospital will have £20,000 worth of radium at its disposal. The book is well produced and fully illustrated, most of the illustrations being borrowed from familiar sources. Dr. Hunt has gathered together a large amount of information, and his book will be useful to those engaged in this special class of work.

INTERNAL MEDICINE.

Lehrbuch der Speziellen Pathologie und Therapie der Inneren Krankheiten. Twenty-fifth edition. By Prof. Dr. ADOLPH STRÜMPELL. Revised and edited by Prof. Dr. C. SEYFARTH. Leipzig: F. C. W. Vogel. Vol. II. Pp. 985.

THE second volume of this popular work on internal medicine deals with disorders of metabolism, diseases of the kidney and urinary apparatus, locomotory organs, blood, internal secreting glands, complete nervous system, including diseases of the membranes of the brain and functional neuroses, such as epilepsy, hysteria, and neurasthenia. Each disease is described under ætiology, pathological anatomy, clinical symptoms, prognosis, diagnosis, and, finally, therapy. Two-thirds of the book is devoted to diseases of the nervous system, and a comprehensive survey is given, with special reference to the pathology of the various conditions. The chapter on hysteria is very complete, with an excellent description of the symptoms and treatment. The book, which is adequately illustrated, is of great value, being authoritative without being unwieldly. No work can attain a twenty-fifth edition without outstanding merits, and the present edition, which has been re-edited, will further enhance the reputation of this text-book.

THE LANCET.

LONDON: SATURDAY, OCTOBER 15, 1927.

SCHOOLS AND INFECTION.

SCHOOL life raises many perplexing problems, not the least of these being the growing recognition of the elementary school as a public health unit as well as an educational unit. How to avoid infection in the schools, and enable the education authority quietly to pursue its way unhindered by epidemic disease, would not be so difficult to determine if the needful premisses were known. Unfortunately, in the case of the common infectious diseases particularly, the natural history of the parasite in the host and of the host invaded by the parasite vary widely with different infecting organisms and with the same infecting organisms at different times. Hence it is probably true that no one can yet tell in advance how a hygienic measure is likely to affect school life, and the school medical service has adopted the limited but valuable rôle of behaviourist, simply drawing deductions from observations now prolonged over a period of years. The latest Memorandum on Closure of and Exclusion from School, issued jointly by the Ministry of Health and the Board of Education is based on actual experiences when exclusion has been tried as a means of suppressing epidemic disease. Observation has, however, been complicated by the fact that until quite recently public health has not been the sole motive in exclusion. Finance has come in, for, when the attendances have sunk owing to individual exclusion to a certain level, it has paid the school managers to close the school. In this respect there has been a sharp clash between the interests of the sanitarian and of the educationist. This has now been rectified and, under the new Code (§ 15 of Administrative Memorandum No. 51, 1927, Code of Regulations for Public Elementary Schools, 1925) the school managers are allowed to omit in calculating average attendance, on which the grant depends, any week which falls below 60 per cent. of the register, when the school medical officer attributes the fall to the prevalence of epidemic illness.

Opposition to school closure may be based on both educational and medical grounds. Whilst the interference with instruction is obvious to everyone, it is less often realised that the closing of a school also makes it harder for the public health authority to control infection among the pupils. No longer under the watchful eye of school medical officer or nurse, their symptoms are apt to pass unrecognised, and an epidemic is the less easily kept in check. The Memorandum lays down as a general principle that, if the power to exclude individual children be used to the best advantage, it is only in special and quite exceptional cases that it will be necessary to close a school in the interests of public health. The exception is well recognised in the case of thinly populated districts where children come far from isolated homes, and school closure may have definite value in preventing the spread of measles from village to village and in avoiding exposure for children already in the early stages of the disease. In the case of diphtheria the Memorandum is satisfied that the diligent exclusion of contacts, in many cases for a long period, should obviate the need of school closure for this infection. Scarlet fever is a disease which spreads slowly from child to child, and here again diligent search for slight cases and supervision of contacts should render school closure very rarely necessary. Closure when desirable need not extend to the whole school and may on suitable occasions be limited to particular classes; but when complete there must be no loophole for the children to meet, and the doors of playgrounds must be shut and the managers of Sunday schools induced to collaborate. Giving the gist of the matter in a sentence, the Memorandum remarks that closure of a school is not justified unless three conditions are simultaneously present: (1) evidence pointing to the continued meeting of children in school as a source of infection; (2) cases of infectious disease continuing to occur after every effort has been made to discover the infecting cause; and (3) good reason to expect that closure will considerably reduce the likelihood of exposure to infection.

The Memorandum deals solely with public elementary schools, although the lessons may have a wider application. The problem of the residential school is of course a separate one, but there is one matter of very keen interest to resident school managers, parents, and school-children alike in which the principles are closely similar. This is the attendance during the holidays of school-children at public gatherings of all kinds. On account of the prevalence of serious illness last Christmas the management of a large boarding-school circularised the parents of the scholars asking them to keep their children away from crowds during the holidays and not to take them to any place of public entertainment during the last fortnight before returning to school. Such a request if loyally observed would inflict great hardship on those children who comply, for their health would be at the mercy of less compliant school-fellows and parents. Moreover, it is doubtful whether the policy implied is of real value. In his presidential address [1] to the Medical Officers of Schools Association in 1926 Dr. A. I. SIMEY said: "I sometimes wonder what would be the result of entirely abolishing our code of holiday quarantine precautions and allowing the infection to enter schools more frequently, but in smaller outbreaks, spreading the incidence, so to speak, over a number of terms instead of crowding an unmanageable number of cases into a few terms at long intervals." The best place for children to get over an infection is, he points out, the home, or failing that the relatively small preparatory school. It is unreasonable, we feel, to ask parents to keep their children away from assemblages of people during the Christmas holidays; it would be bad for the parents and unfair to the children. Only under conditions of grave danger would such prohibition be justifiable, and then the instruction should emanate from some central authority. On the other hand, it would be quite reasonable to ask parents not to take their children to assemblages, whether parties, theatres, or cinemas, for a clear week before term-time. If to this direction the boarding-schools added the practice of taking each pupil's temperature at night for the first clear week of the term the danger of infection spreading would be materially lessened. We are raising this question at the beginning rather than at the end of the Michaelmas term in order to give school medical officers the opportunity of issuing some sort of concerted advice with regard to the Christmas holiday population; it would be well if some uniform system were tested and its results noted.

THE TEACHING OF SURGICAL ANATOMY.

As advance in medicine takes place we see new and intricate methods of diagnosis devised, the chemical changes underlying many diseases revealed, the resources of physical science called upon for treatment, the horizon of bacteriological and immunological science ever enlarging. No perfunctory method of study will now serve to equip the medical student for his future work in life. He must go through a strenuous, exacting, and prolonged course. The curriculum becomes more and more crowded as the specialists in the different branches of medicine claim to have each his own subject embodied in it. This process of inclusion must inevitably reach a limit beyond which it is inadvisable to go, for it is necessary to train practitioners who, as the subdivision of medical knowledge proceeds, preserve a broad outlook, free from all trace of those obsessions which beset the enthusiastic worker in a limited field. Indeed, it is questionable whether it would not be in the interests of the public and their doctors if some curtailment of the medical curriculum were not to be enforced even now. This applies almost as much to the basic sciences of anatomy and physiology as to the more recent growths of biochemistry and radiography. Anatomical knowledge is indeed necessary for diagnosis and for the surgical operator, but it may well be asked by the reader of such a book as that by Prof. DEAVER [1] on "Surgical Anatomy of the Human Body" whether already too much is expected of the student. Here is a treatise on anatomy written by a surgeon with the surgeon's needs in view. It is beautifully illustrated; the pictures are realistic in the impressions they give. Everything the surgeon could conceivably desire to know, every relation which could possibly be of importance to him is described and figured. It is an exhaustive treatise on surgical anatomy, it is wellnigh perfect of its kind—but it is a book of 2168 pages in three large volumes. Should a student during the clinical years be expected to read such a large volume? Should it be necessary, after two years' study in the dissection room, for him to read it? Now that the teaching of anatomy in the earlier years is in the hands of specialists it is essential for instruction in so-called surgical anatomy to be continued later, for until the student has some clinical knowledge he cannot get a grasp of surgical problems. But when it comes to arranging the scope of such a course, difficulties arise. For the future surgeon an accurate and deep knowledge of anatomy is essential. Most inaccessible structures are apt suddenly to assume surgical importance as the understanding of disease becomes more exact. The development of pituitary surgery, the introduction of splanchnic anæsthesia, illustrate how the most abstruse anatomical relations enter into practical everyday operating. But for the future general practitioner too extensive a course of surgical anatomy may deprive him of clinical opportunities which will not recur. It might be a wise policy for instruction in surgical anatomy to be restricted so as to comprise only that which is helpful in the diagnosis of disease or necessary for the performance of the common operations and especially those urgent procedures which every doctor may be called upon to carry out. Those on whom it falls to devise medical curricula should insist upon the instillation of principles, upon broad generalisations, and a wide outlook. Detailed information can always be obtained from books; for this purpose the only essential is for the worker to know of the existence of such knowledge and where it can be obtained. If the newly qualified practitioner has absorbed the basic principles of his art, if advanced demonstrations have opened up for him a vista of the refinements of science without clogging his perception with needless detail, if, in fact, he approaches his work with the right mental attitude and equipment, defects in special knowledge will not handicap him in his dealings with his patients. They can be remedied easily by reference to trustworthy sources of information.

[1] Surgical Anatomy of the Human Body. Second edition. By John B. Deaver, M.D., Sc.D., LL.D., F.A.C.S., Surgeon in Chief to the Lakenau Hospital, Philadelphia; Emeritus John Red Barton, Professor of Surgery, University of Pennsylvania. London: William Heinemann. 1927. Vol. i., pp. 551; vol. ii., pp. 854; vol. iii., pp. 763. 8 guineas the set.

A CRITIC OF THE JURY SYSTEM.

AT the latest of the provincial meetings of the Law Society, held at Sheffield recently, a member read a paper on The Jury System: Its Cause and Cure, in which he criticised as unsuitable and unsatisfactory the present system under which it is left to juries to assess damages upon allegations of negligence in the certification of lunatics. The critic proposed to substitute trial of such cases in camera before a special tribunal consisting of a medical practitioner, a solicitor, two trained professional jurymen, and (as chairman) a barrister or judge. Evidently some of the recent decisions of juries at the expense of certifying doctors have awakened surprise and misgiving outside the ranks of the medical profession.

The trained professional jurymen whom the speaker at Sheffield had in mind were to be a new type. They were to be persons who had had 15 years' experience in some trade or business (not being a profession) on their own account, or as directors of a public trading company for a like period. They should have retired from business, attended a special course at a school of law, and passed a qualifying examination in knowledge of the rules of evidence. They should have a salary of £1000 a year, and should attend as required at one court or another, thus adding constantly to their intellectual and judicial stature till they became supremely competent assistants to a presiding judge. Five of these trained and salaried jurors should go to each ordinary jury and they were to be available, it seems, not merely in the High Court, but in the county court and at coroners' inquests as well. Juries, the speaker explained, had developed from remote origins to their present character and functions by a series of adaptations. His present proposal would merely adapt the system afresh so as to get the best value from it and so as to ensure to litigants the fullest and most careful consideration of their cases. Other speakers who followed were not so sanguine. Many feel that a juror should be paid his reasonable expenses, but they deprecate the institution of a class of professional jurymen who would contract fixed ideas and acquire an official point of view while losing the common sense outlook which is so valuable a corrective in the administration of justice.

The defects of the existing jury system are many. Jurors have no individual responsibility; they give no reasons for their verdict; their verdict as such is not subject to appeal. Many men who are summoned to serve on a jury are so deeply concerned over the enforced neglect of their business that they cannot give proper attention to their high judicial functions. Nor were these the only criticisms of the jury system uttered at Sheffield. It was said that jurors tend to reflect the popular prejudices of the

day, particularly in periods of political excitement, that they are liable to bias, and that they are always more likely to decide in favour of a well-dressed pretty woman than in favour of a railway company or a municipal corporation. Finally, it was complained that our jurors are utterly untrained, and yet have to decide intricate questions of disputed fact, while endeavouring to reconcile their individual conclusions with the prescribed unanimity. Nobody can deny the existence of these disadvantages, yet so competent an observer as the Lord Chief Justice has stated that there is nothing to be gained by abandoning the present haphazard method of selecting jurymen and by substituting panels of specialists. Lord Birkenhead shares Lord Hewart's view; out of all the thousands of cases in which he was engaged at the Bar he can recall only three in which a jury came to a wrong conclusion. Judges are happily contented with the instrument with which they are accustomed to work; the general public is comfortably reassured by the infusion of a lay element into the administration of justice. But there is neither contentment nor reassurance for the medical profession when immense damages are wildly awarded against practitioners who are discharging a public duty under the Lunacy Act with an illusory statutory protection—this is a position which demands reform.

Annotations.

"Ne quid nimis."

A WEST-COUNTRY ANTI-RHEUMATISM CAMPAIGN.

A MEETING held on Oct. 1st at the Bristol General Hospital inaugurated a campaign which, as our readers are aware, has been in preparation for some time. The meeting was attended by the officers of the school medical services of Bristol, Gloucestershire, Somerset, and Wiltshire, including those of county boroughs within their borders, and by a group of consulting physicians practising within the same area. The purposes of the organisation which this meeting brings into living activity are, first, research into the conditions under which children contract rheumatic heart disease; and, secondly, assistance in the treatment of such children. Practitioners within the area have been invited to send brief notes of cases arising among their patients. For this purpose the disease has been defined as follows:—

(1) Heart disease arising in connexion with rheumatism, chorea, or scarlet fever in a child between the ages of 5 and 14 inclusive.

(2) Heart disease which, though not arising in connexion with rheumatism or chorea, is nevertheless rheumatic in type—i.e., ventricular enlargement with mitral incompetence, with or without aortic incompetence or acute pericarditis—arising in a child between the ages of 5 and 14 inclusive.

It is probable that a considerable percentage of the cases that fall within the second part of this definition will be brought to light by the work of the school doctors. Further, there is little doubt that close attention to the problem of diagnosis of the disease in its early stage will be of immediate value to the school medical service. This at all events has been the experience in Bristol, where the plan about to be described has been on trial for several years past. It has been found that reference of children with signs suggestive of cardiac rheumatism to hospital physicians interested in the matter has resulted in the removal of restrictions with regard to school attendance, games, drill, and the like in a large number of instances, and in others has been the means of directing children in the early and more tractable phases of the disease into channels of treatment that might otherwise have been missed. On the strength of these arguments and experiences the local authorities in the areas named have decided to make arrangements by which children, in whose cases the school medical officers think it desirable, may be seen at convenient places by physicians with special experience in this disease.

This plan has the support of the Board of Education. The area comprised within the three counties named is fortunate not only in having at its centre a city in which work of the kind has already been done, but also in possessing medical officers in all the areas who have already had administrative experience of similar organisations. Moreover, they have undertaken to conduct inquiries into the conditions under which the children are living at the time of onset of the disease; and since this district includes a wide range of variations in soil, altitude, density of population, and so on, information of value should be forthcoming. The investigation, which was initiated by the Cardiac Subcommittee of the Science Committee of the British Medical Association, has for its focus the University of Bristol Centre of Cardiac Research. This is housed at the Bristol General Hospital, equipped by the University of Bristol, and maintained by several grants. Among these may be mentioned one from the Medical Research Council for clerical expenses; also a Research Fellowship provided for two years by the Colston Research Society, a Bristol organisation. To complete this machinery which is in process of being set up, it is hoped to devote a number of beds in the country hospital shortly to be built at Winford, near Bristol, to the treatment of cardiac rheumatism in childhood. The site has been carefully chosen, and is believed to be the best within a convenient distance from the city.

HYGIENE IN AMERICAN COLLEGES.

AMERICA has no equivalent of the English public schools, but in many ways the smaller colleges are more reminiscent of public school traditions than any other part of the American educational system, witness the "hazing," which term includes "fagging" of freshmen by sophomores and the intense "college spirit" in athletics among the less creditable resemblances. It would appear that inadequate medical supervision is another if a recent report to the Presidents' Committee of Fifty [1] is to be taken with due solemnity. Dr. Storey's conclusion is that "the evidence assembled in this report brings out the fact that the great majority of the institutions . . . . are not furnishing opportunities for a competent general education in hygiene to the young men and young women . . . . Few leaders are equipped with a knowledge of scientific hygiene, and very few are trained for leadership in hygiene." The theological schools appear to be the worst sinners, for out of 101 reporting only 15 give a general medical examination to their students. On the other hand, such an examination is given in 118 of 142 colleges and universities. It is true that the examination is not always as thorough as it should be, but a beginning has certainly been made. In some colleges standards are being set that it may be hoped will gradually raise the level. A powerful factor to this end is the American Student Health Association, a growing and increasingly influential body with national and regional organisation that claims adherents from most, if not all, the colleges and universities that have progressive departments of student health. A valuable report on the present status and future possibilities of this work was published a year ago by the then secretary of this Association, Dr. Warren E. Forsythe,[2] with a bibliography of 268 references to published articles which shows to what an extent the subject has been already discussed in America. Nevertheless, we are disposed to agree with Dr. Storey that without properly trained leaders the progress of the movement must be slow and, we might add, erratic.

HODGKIN'S LYMPHOGRANULOMA.

A HUNDRED years ago Bright and Hodgkin began to doubt the "cancerous nature" of the nodules in a certain type of spleen, and we learn that Bright gave great credit to his colleague for assigning to this disease a separate place in the museum at Guy's. Thirty years later the discovery was wrongly attributed to Wilks, but he, "with the generous desire to perpetuate the name of his predecessor," insisted that this entity be known as Hodgkin's disease. In the intervening years pathologists, including Sternberg, Reed, Andrewes, and Turnbull, have taught that the condition bears the anatomical and histological hall-marks of a granulomatous inflammation. According to their view the "infiltration" of vertebræ, spinal dura mater, and spinal nerve-roots mentioned elsewhere in this issue of THE LANCET is essentially an inflammatory lymphogranulomatous infiltration. Lymphadenoid tissue anywhere in the body may be picked out by this process so that glands, spleen, liver, kidney, and bones are commonly affected; and the infiltration may spread to adjacent organs, for example, the mediastinum and lungs. It is less usual, but certainly not rare, to find the lymphadenoid tissue of the alimentary tract picked out, the "Hodgkin nodules" being found in the stomach, solitary follicles, and Peyer's patches. This brings to our consideration the so-called large-celled lymphosarcomatosis (Hammerschlag, Kaufmann) or Hodgkin sarcoma (Ewing). In this condition the stomach, intestine, and mesenteric glands may be extensively "infiltrated," and the spleen often shows a "lymphadenoid hyperplasia." Here the infiltration bears yet another distinctive histological picture, perhaps more like a neoplasm and less like a granuloma. There is, however, a growing mass of evidence, associated especially with the name of H. M. Turnbull, that this condition is allied to the "Hodgkin lymphogranuloma." The true place of other, less marked "lymphadenoid hyperplasias" in this disease-group cannot, of course, be settled until the problem of ætiology is determined.

Thus history repeats itself; for to-day, with an advance of a hundred years in our histological criteria, we place on our museum shelves Hodgkin's disease classified as a lymphogranuloma with "lymphosarcomatosis (so-called)" near by. Meanwhile, there is reason to suppose that many of the phenomena of Hodgkin's disease commonly described as rare are seen quite often by present-day morbid anatomists. Probably a very large amount of pathological material which would throw light on these subjects lies dormant in the great hospitals, and the question arises whether our modern Brights and Hodgkins are not so fettered by routine duties that they cannot publish what they know. We hope that they may live to do so; and also that a modern Samuel Wilks may be found with a generous desire to perpetuate their names.

THE LESSONS OF THE CÆSAREAN OPERATION.

A FEW weeks ago [1] Mr. St. George Wilson described in our columns three cases of rupture of the uterus through the scar of a Cæsarean section, whilst in our present issue Dr. Margaret Salmond reports six cases in which patients previously operated upon were delivered by the natural passages in subsequent pregnancies. Mr. Wilson's cases illustrate the possible serious consequences that the Cæsarean operation may have in later pregnancies and labour. From the figures of the collective investigation in the large general and maternity hospitals throughout the country, Eardley Holland, in 1920, showed that the frequency of rupture of uterine scars was about 4 per cent. of all cases in which pregnancy occurred after the operation and reached a late stage. He also found that rupture was nearly as frequent in pregnancy as it was in labour. The evidence pointed to the immediate cause being imperfect healing of the uterine incision with the formation of a thin scar which ruptured under the increasing tension of the developing gestation or the strain of labour. Probably sepsis and the physiological processes of involution both played a part in determining the imperfect healing. The rarity of uterine rupture in pregnancy or labour following the much more extensive wounds produced by the removal of myomata from the non-pregnant uterus in the operation of myomectomy favours the view that the processes of involution are in themselves a prominent factor in the production of a weak scar, and on this ground the lower segment operation has been strongly advocated by Prof. Munro Kerr, of Glasgow, as lessening the risk of rupture. Though the after-history of cases operated on by the low operation has as yet been reported in too few cases for a final decision, the evidence so far as it goes seems to indicate a greatly diminished risk.

Writing from another standpoint, Dr. Salmond draws attention to the temptation to adopt the Cæsarean operation as the easiest method of avoiding what may possibly be a difficult delivery by the natural passages. When this is done nothing is learnt of what the natural powers can do if given a fair chance, for all our measurements and methods of determining the fit of the head into the brim have not a tithe of the accuracy of the actual experiment of a labour carefully conducted and observed. Dr. Salmond therefore pleads for a trial labour continued long enough to decide with fair certainty on the need for delivering the child by an abdominal operation, and the lesson of these two papers is that greater hesitation should be exercised before resorting to Cæsarean section. A history of difficult labours and dead-born children or a single carefully observed labour is the clearest indication in all but the marked degrees of pelvic disproportion. Especially in young women must the temptation be resisted to perform an operation that carries with it both a greater immediate risk and a definite remote risk in every succeeding pregnancy, unless a trial labour or the induction of premature labour three or four weeks before term is clearly out of the question. Rather than increase the risks to the mother in all future pregnancies it is good practice to take an increased risk of loss of or injury to the child in the first.

[1] THE LANCET, Sept. 17th, p. 598.

VITAMIN D IN GREEN PLANTS.

THERE still seems to be some confusion about the antirachitic value of green food, although the results of recent work on the subject are quite clear. The confusion is undoubtedly a legacy from the time before the fat-soluble vitamins were differentiated. It was believed at that time that vitamin A and the antirachitic vitamin D were identical, and tests which revealed the presence of vitamin A were held to be an index of antirachitic potency also. In this way green vegetables, which are undoubtedly extremely rich in vitamin A, were deemed to be also rich in antirachitic vitamin; later work has shown that they do not commonly possess this value in any marked degree. H. Chick and M. H. Roscoe (1926), following up the work of E. M. Luce (1924), found that the power of pasturage to raise the antirachitic value of cow's milk is due more to the sunlight which the cows enjoy out of doors than to the green food which they consume. In tests on rats A. F. Hess and M. Weinstock (1924, 1925) found no antirachitic value in fresh lettuce leaves; H. Goldblatt and S. S. Zilva (1923) and T. F. Zucker and M. Barnett (1923) found none in spinach leaves, and Chick and Roscoe (1926) exhaustively examined spinach leaves and found no antirachitic value in them under any conditions, except at the height of summer when a very slight antirachitic effect was observed. But they found, as did Hess and Weinstock with lettuce leaves, that the spinach leaves when exposed to an artificial source of ultra-violet light became potently antirachitic. The reason for the apparen

non-activation of leaves exposed to sunlight remains a mystery, but the possibility exists that the overwhelming preponderance of vitamin A in green leaves, under the conditions of the experiment, somehow masks the presence of a small amount of vitamin D, perhaps because the growth produced in the experimental animals, receiving the green leaves, is much greater than the growth of the controls. A small degree of antirachitic activity has been detected in green alfalfa by H. Steenbock and co-workers (1922), by W. G. Gaessler and A. C. McCandlish (1923), and by E. V. McCollum and his co-workers (1924). It must, however, be concluded that the antirachitic value of green food is usually very slight, and in no way comparable with its richness in vitamin A, as as was at one time supposed.

The same misconception as applies to terrestrial green food also exists with regard to the green food of the sea. It used to be held that the codfish obtains the vitamin D, in which its liver oil is so rich, from its food and that the ultimate source of vitamin D for all organisms in the ocean is in the green algæ and diatoms which inhabit it. These, it was believed, form their vitamin D under the influence of direct insolation. It had been shown by H. L. Jameson, J. C. Drummond, and K. H. Coward [1] in 1922 that the marine diatom, *Nitzschia closterium*, is a rich source of vitamin A, and confusion as to its antirachitic power came about in the same way as happened with terrestrial green food. In a paper published this year J. L. Leigh-Clare[2] has disposed of this comfortable theory of the origin of vitamin D in the sea and has shown that *Nitzschia closterium*, grown with conditions of maximum insolation, has no antirachitic power. So we are still left in doubt as to which organisms provide the vehicle by which vitamin D is supplied to the inhabitants of the sea. Since the green ones are not responsible, possibly the surface baskers among the animals play a more important part than had been supposed, or possibly even, as C. E. Bills [3] suggests, vitamin D can be elaborated in the body of some marine animals, without the intervention of light. Unfortunately, however, there is still no definite answer to the frequent question: "Where does the cod get its vitamin D from?"

CONTROL OF HÆMORRHAGE DURING TONSILLECTOMY.

REMOVAL of the tonsils is perhaps the most frequently performed operation of surgery. Dr. Walter A. Wells, of Washington, states that in America it is almost the exception to find a person who, either in childhood or adult age, has not had it performed. Although it is to be hoped that the operation will never reach such a degree of popularity in this country—for it cannot be really necessary in so large a proportion of the population—it is nevertheless an advisable and beneficial procedure in a large number of patients. The great bugbear of the operation, especially in the mind of the public, is bleeding, which usually comes on as reactionary hæmorrhage a few hours after the operation. Even when the quantity of blood lost is not enough to be alarming, it may be sufficient to retard convalescence and is disturbing to the patient. For some time past, surgeons have been giving increased attention to their technique, with a view to preventing undue bleeding during the operation and to reducing the frequency of reactionary hæmorrhage after it; many surgeons now make it part of their routine to ligature any bleeding-point which persists, even in a small degree, after sponge-pressure has been applied for a few minutes. With this criterion most adult tonsils require one or more ligatures, but they are rarely necessary in young children; and there is no doubt that the adoption of such a routine materially adds to the comfort and safety of these patients. Dr. V. K. Hart, of Statesville, N.C.,[1] since tying bleeding-points during operation, encountered 14 cases of post-operative hæmorrhage in 800 cases, in eight of which further ligation was required. The chief reason against the universal adoption of primary ligature is its difficulty, for it is no easy matter to tie off a vessel in the tonsillar bed in the manner ordinarily employed in more accessible wounds; but technical difficulty is no valid excuse for non-performance, and it may reasonably be said that no one should attempt to remove a tonsil unless he is able to ligature a bleeding vessel in its bed. The simplest method of securing the bleeding-point is to pass a slip-knot of braided silk, held by a long forceps, over the hæmostat after the method of C. G. Coakley [2]; but this, too, requires considerable practice, and many ingenious instruments have been designed with a view to making ligation easier. Of these one class is a modification of the hæmostat forceps, providing a shoulder or a rounded end to enable the ligature to slip off it more readily; others provide an arrangement by which the loop of ligature is attached to the hæmostat and carried on it into the bed of the tonsil. An instrument of this type has been recently described by Dr. Angelo J. Smith, of Yonkers, N.Y.,[3] in which a sliding rod attached to the hæmostat carries the ligature at its distal end; on pushing down the rod, the ligature is brought beyond the point of the forceps into position for tying. Sir James Dundas-Grant achieves the same result by passing the slip-knot inside a metal or glass tube in the manner described in our last issue,[4] where Mr. Norman Eadie also describes his device of employing a hole drilled through the tip of the hæmostat as a pulley. Of another type is the instrument designed by Dr. Wells [5]; it is in the form of a forceps in which a short slotted needle is fixed to the end of one blade; on closing the instrument over the bleeding area and opening it again, a double thread is placed through the tissues at the point required, which can then be tied on the fingers in the usual way. Different operators will, of course, prefer different instruments, but there is no doubt that instruments which facilitate the technique of ligature will conduce to its more regular performance and so make bleeding after tonsillectomy a rarer occurrence.

THROMBOSIS OF THE SPLENIC VEIN IN CHILDHOOD.

SPLENIC anæmia is the name applied to the syndrome of severe anæmia, accompanied by considerable splenic enlargement, for which no clear cause such as rickets or syphilis can be found. The anæmia is of secondary type—that is to say, the reduction of hæmoglobin is out of proportion to the diminution in the erythrocytes. The classification of such cases is made more difficult by the fact that anæmia and slight splenic enlargement may result from many minor degrees of ill-health. In rare instances hæmatemesis or epistaxis are early symptoms. Cases tend to run a chronic course of from 3 to 12 years with the supervention of cirrhosis of the liver and secondary ascites later. This latter complex constitutes Banti's disease. It is not clear to what extent splenic anæmia if left to itself develops the full picture of Banti's disease. Removal of the spleen in the early stages has sometimes resulted in a cure, but once cirrhosis of the liver has developed splenectomy has had no effect. Whether the successful cases would have developed into Banti's disease later, or whether they belonged to another type, is as yet undecided. The success of operative treatment has led to the theory that there is primarily a morbid increase in blood destruction by the spleen which is cured by its removal. Thrombosis of the splenic vein has also been suggested as a cause, and in a recent monograph

Dr. Arvid Wallgren[1] has attempted to isolate a group of cases in which it was primary. He describes in great detail his investigation of four patients at the Infants' Hospital in Göteborg, and supplements these observations by a résumé of similar cases from the literature. Apart from secondary anæmia and splenic enlargement, his children all had attacks of profuse hæmatemesis in the early stages of the disease, these attacks bearing a definite relation to the size of the spleen, each loss of blood being followed by reduction in size of the organ which then enlarged again. In support of thrombosis, he emphasises the following facts which he observed in his four cases. The vessels and parenchyma of the three spleens removed at operation were engorged with blood as though the venous circulation was obstructed. The veins of the collateral splenic circulation were greatly enlarged. Thrombi were found in many of the smaller branches of the splenic vein. No actual thrombi were detected in the splenic vein itself at operation, but the examination was necessarily cursory. In the fourth case, which died after a severe hæmatemesis, thrombosis of the splenic vein was present. The effect of hæmatemesis on the size of the spleen he explains as follows. The pressure of the blood dammed back in the spleen by the obstructed vein finally becomes so great that one of the gastric or œsophageal branches of the collateral circulation ruptures into the stomach, tension in the spleen is relieved by hæmorrhage, and the organ becomes smaller in size. Eventually the establishment of an adequate collateral circulation might prevent further hæmorrhages, but extension of the thrombus would still be liable to cause further engorgement. The cardinal point in the diagnosis of thrombosis of the splenic vein is the association of splenic enlargement with hæmatemesis early in the disease, hæmorrhage being followed by a reduction in size of the organ and cessation by an increase. Owing to the danger to life from repeated hæmatemeses and progressive anæmia, Dr. Wallgren considers splenectomy the treatment of choice in these cases in spite of its dangers. The three patients in whom the spleen was removed were quite healthy two years or more after operation and had had no further bleeding.

This monograph brings strong evidence to show that there is a group of cases which might have been classed as splenic anæmia, but which are actually due to thrombosis in the splenic vein, and for which early splenectomy gives the best chance of permanent health. In England profuse hæmatemesis is a very rare symptom in children between 2 and 11 years of age, even in cases with splenic enlargement.

A WINTER TOUR IN SWITZERLAND.

CLIMATE is a ubiquitous study, but apart from our own it is probable that few members even of the medical profession realise what are the precise conditions of the climate, physical, intellectual, social, hygienic, into which they send their patients during the winter. We therefore cordially welcome the opportunity offered to practitioners by the Council of the Royal Institute of Public Health, with the collaboration of Sir Henry Lunn, of studying climatic conditions in all the more important parts of Switzerland. The tour is not to be hurried, and it will be possible to combine instruction with recreation, and particularly with that change of scene, right in the middle of our sunless winter, which has been shown by so many ex-Alpine patients to be a factor in maintaining their health. The party will leave London at 2 P.M. on Sunday, Dec. 18th, and the following day will reach Zürich, where they will visit the hospitals and university. Wednesday will be spent at Arosa, the highest health resort in Switzerland; Thursday and Friday will be devoted to Davos, where the party will be entertained by the Kurverein, and the next four days, including Christmas, will be passed at St. Moritz and Maloja, so as to see something of the winter sports. On Tuesday, Dec. 27th, the party will drive into Italy to reach the Rhone Valley and will spend the night in Milan, after which they are to return to Switzerland to visit Montana, as the guests of Sir Henry Lunn, and to see Dr. Rollier's famous clinic at Leysin, where the tour will end on Dec. 30th. The participants will then be at liberty to return to England or remain in Switzerland as they please. Further particulars may be had from the hon. secretaries of the Institute at 37, Russell-square, London, W.C. 1.

HAIR DYES.

THOUSANDS of years of experiment have failed to provide a hair dye which is definitely harmless and at the same time satisfies the popular demand. Dr. O. L. Levin, in the *Medical Journal and Record* of August 17th, divides the dyes in common use into three classes—the purely vegetable, of which henna is alone convenient, the metallic, and the synthetic organic. Henna is harmless, but will only dye the hair red, the so-called brown or black henna dyes containing metallic compounds. Metallic dyes, which form the bulk of the preparations usually exposed for sale, are most of them composed of a salt of silver, copper, mercury, tin, lead, or bismuth, mixed with a developer, which is usually pyrogallic acid. Silver dyes may contain sodium thiosulphate instead. The depth of the tint obtained depends on the amount of copper deposited as a sulphide on the surface of the hair. The pyrogallic acid corrodes and ultimately destroys the hair, and the copper is absorbed by the body in quantities that may be physiologically toxic. The danger of all metallic dyes lies in the necessity for their repeated application, which affords an opportunity for the metal to accumulate in the tissues and produce an obstinate illness. Lead is particularly poisonous and there is little doubt that its use should be absolutely prohibited. Probably the only metallic salt that is quite harmless is permanganate of potash, which is too slow and uncertain in its action to be of much value. The synthetic dyes are prepared on a base of paraphenylenediamine, a derivative of aniline, and are so noxious that nearly every European country forbids their use. They penetrate the hair-shaft and so give a much more lasting result than the metallic compounds. But for their virulent effect they would solve the problem very well. The symptoms that may be caused by poisonous hair dyes are local or constitutional, or both. The local reaction may be an acute dermatitis extending over the head, neck, face, and ears, and proceeding to œdema and vesiculation. This sometimes clears up untreated in a few days, but often the violent itching makes the patient scratch, and eczema and other secondary ailments follow. The itching may persist for months under treatment after the eruption has disappeared. Cutaneous tests may discover whether a given person is likely to react to a dye in this way, but probably no one is quite immune from constitutional metal poisoning, and users have been known to react locally after tolerating many previous applications. Short of prohibiting the sale of all dyes containing noxious substances, as has recently been done in New York, it is useful to insist on their correct description at sale.

SYNDROMES IN PHARMACOLOGY.

WHY adrenalin acts specifically on the sympathetic terminations, or why apomorphine attacks the vomiting centre, are examples of a question which pharmacology has so far failed to answer. Any method which suggests an approach to this fundamental problem of the specific action of drugs is welcome. Certain simple reactions can be explained; the astringency of tannic acid, for instance, is generally admitted to be due to the coagulation of proteins, and saponins bring about hæmolysis by dissolving the lipoid constituents of the cell envelope. Nevertheless these phenomena are exceptional, and the bulk of

pharmacology is still empirical. Prof. J. A. Gunn, in his presidential address to the Therapeutical and Pharmacological Section of the Royal Society of Medicine on Tuesday, Oct. 11th, pointed out this limitation clearly, and suggested a concept that he and others believe may be of some assistance in the huge task of removing it. It is a commonplace that many dissimilar substances have similar effects on the organs of the body; ipecacuanha, tartar emetic, senega, and squill, for instance, all produce emesis and increased secretion of the sweat and salivary glands and of the bronchi. This group of reactions, produced by a variety of substances having chemically nothing in common, may appropriately, he says, be called a syndrome. Since they are due to a common and explainable physiological mechanism they deserve the qualification of "homogeneous." It is, however, the "heterogeneous" class of syndromes that Dr. Gunn anticipates may one day be of greater scientific importance; that in which the similarity of effect cannot be related, in the light of present knowledge, to known physiological or biochemical facts. While investigating a new alkaloid known as harmaline he found that it had a powerful toxic action on protozoa, impaired the conductivity of nerve, arrested the perfused frog's heart in systole in strong solutions and in diastole in weak concentrations, stimulated the mammalian uterus and, in fact, recalled the actions of quinine. He argued that, if the resemblance were more than accidental, harmaline should, like quinine but unlike most alkaloids, produce a rigor of the voluntary muscles, and experiment proved that it did. He also found that it cured acute and relapsing malaria. Now there is no known chemical resemblance between these two alkaloids which could explain their similarity of action, and the syndrome is one for which no common physiological basis can be found. It is a heterogeneous syndrome. The possible explanations are several: there may be an undiscovered chemical affinity between the two drugs; the syndrome may be really homogeneous, due to some unsuspected effect on, for instance, the blood composition; or—and this is a supposition that opens up wide vistas of speculation—there may be some chemical similarity between the various nerve centres which ensures that two given drugs, even if they have chemically nothing in common, which attack one centre will attack all. There is, as every investigator in this field knows, distinct evidence of "trends" in selective action; of the preference of chemically dissimilar substances for physiologically dissimilar tissues. Physostigmine stimulates all parasympathetic endings (an homogeneous syndrome), but in higher concentrations it stimulates the nerve ends in striped muscle. Atropine, which has nothing in common with physostigmine, neutralises both these actions. The inference is that there is a chemical similarity between the two types of terminals—a hypothesis which is supported by several authorities. These are only a few examples of a range of associated phenomena, "syndromes," which must widen daily as the science of pharmacology advances. Study along these lines promises a reward outside the scope of the usual attempt to correlate physiological action with chemical constitution, which the increasing complexity of chemical research is showing more and more clearly to be impracticable.

WE regret to record the death at Buenos Aires on Oct. 8th of Sir John O'Conor, the resident medical officer of the British Hospital in that city.

IT appears to be an open secret that the successful swimmer of the Channel, who walked on shore at Folkestone on Tuesday morning last, and whose triumph is attributed to a "Miss Mona McLellan," is in real life Dr. Dorothy Logan. Dr. Logan, who is in charge of one of the female special departments of King's College Hospital, has gained a victory after several notable attempts, having on a previous occasion got within a mile and a half of Dover after swimming for 25 hours.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXLV.—TREATMENT OF LOBAR PNEUMONIA, BRONCHO-PNEUMONIA, AND BRONCHITIS IN CHILDREN.

I. GENERAL CONSIDERATIONS.[1]

ALTHOUGH classical examples of these three conditions are distinguishable, there are many borderline cases in which diagnosis cannot be made. Since exact differentiation, though desirable, does not affect treatment, which is mainly symptomatic, they are here considered together with certain reservations.

Briefly the three conditions may be outlined as follows:—

In *lobar pneumonia* the infecting organism in nearly every case is the pneumococcus and the distribution of the inflammation in the lung is lobar. If there are no complications the temperature usually reaches normal by lysis or crisis within a week of onset. Although not generally recognised as such, this is probably the commoner pneumonia of childhood. The disease becomes increasingly severe with increased age and weight. In children under two years old without complications, the degree of illness is slight and the signs of consolidation often transient. When this is so diagnosis is often a matter of opinion.

In *broncho-pneumonia* the infecting organisms are streptococci, staphylococci, pneumococci, *B. influenzæ*, and others. The distribution of the inflammation is lobular, but this is often not shown by physical signs, because a lobular consolidation often makes a whole lobe solid. In children it occurs most frequently in connexion with influenza, whooping-cough, and measles, and in these bronchitis often precedes it. Broncho-pneumonia is a very severe disease; the temperature remains high for several weeks, cyanosis is a marked feature, and death the usual termination. Should recovery occur some degree of fibrosis of lung will probably remain.

Bronchitis.—The severity of an attack of bronchitis depends on the extent to which the bronchial tubes are involved. If only the large tubes are affected it is a mild disease. If, however, the inflammation has extended into the smallest bronchioles the clinical picture merges closely into that of broncho-pneumonia and the physical signs of the two are often identical. To what extent an acute bronchitis may develop into broncho-pneumonia is not at present quite clear. Possibly the type of organism determines this, and accounts for the fact that the bronchitis of measles, whooping-cough, or influenza appears to develop into broncho-pneumonia while ordinary bronchitis does not do so to the same extent.

Prevention.

Bottle-fed babies and debilitated children, especially those with a tendency to rickets, are particularly liable to develop bronchitis and pneumonia. There is no specific mode of prevention, but avoidance of cold and damp probably lowers the incidence considerably. The development of bronchitis during an attack of whooping-cough or measles or in an influenza epidemic is a signal for special care.

Differences Between Pneumonia in Adults and Children.

Pneumonia, like other acute diseases in children, is often ushered in by convulsions. This is especially so in apical pneumonia which is commoner in children. The possibility of meningitis should not be forgotten, but too hasty lumbar puncture to exclude this diagnosis is wrong. The rapidity and type of respiration are the best guide to early diagnosis. Abdominal pain is specially frequent in children at the outset of lobar

[1] The concluding section of this article—Special Symptoms—will appear next week.

pneumonia and may make the diagnosis from acute appendicitis very difficult. Again, the rapidity and type of respiration are the best guide. If in true doubt it is better to open the abdomen unnecessarily in lobar pneumonia than to fail to operate in acute appendicitis on the assumption that the child is probably suffering from pneumonia. Many cases of lobar pneumonia in children operated on by mistake do well. The younger the child the less is the danger of cardiac failure. In mild attacks the strain upon the heart is very slight and convalescence is correspondingly rapid.

When first called to see a child with broncho-pneumonia it is important to remember how often this is a complication of whooping-cough or measles. If the history is indefinite the child should be isolated until the possibility of infection has been excluded.

General Management.

Successful treatment depends as much on the nurse as the physician. In severe cases the value of a good trained nurse cannot be over-estimated. The child should be put to bed in an airy room at even temperature. Contact with other children should not be allowed.

Diet.—While there is pyrexia a fluid diet is best. Milk, whole or diluted, is suitable for most children, but mutton or chicken broth, beef-tea, barley-water, and lemonade are also valuable. Fluids should be given freely. Feeds should be small in quantity and given every two or three hours. In severe cases with digestive disturbances, whey or albumin water are valuable, and in mild ones custard, junket, milk pudding, and Benger's food may be allowed.

In some children there is a tendency to acidosis. When this is suggested by drowsiness and apathy, associated with acetone bodies in the urine, the amount of fat in the diet should be limited and carbohydrates given freely. Milk is then not a good article of diet on account of the high percentage of fat it contains, but sugar should be given freely dissolved in lemonade.

Care of the Nose and Mouth.—It is important to keep the mouth as clean as possible. A septic throat, suppurating middle ear, or purulent nasal discharge is often traceable to neglect of this precaution. A weak antiseptic mouth-wash of carbolic or potassium permanganate should be used for this purpose. Obstruction of the nasal passages by catarrh is sometimes a cause of increased dyspnœa. They should be kept as clear as possible by encouraging the child to blow the nose. When this is not effective and nasal obstruction seems to be the cause of respiratory distress, the anterior nares may be cleared with pledgets of cotton-wool and gently irrigated by warm boric and bicarbonate solution (aa ℥i. ad Oi.) with a small syringe. This should not be done unless the obstruction is definitely distressing the child. To do it as a routine is, in all but a few cases, only meddling with a sick child unnecessarily.

Purgation.—At the outset it is well to give a purgative; gray powder is suitable for children under 3 and calomel followed by salts for older ones. Subsequently syrup of senna, senna pods, or cascara are appropriate laxatives. Symptoms should be dealt with as they arise and are discussed below under separate headings. No routine treatment is indicated. Rapidity of convalescence depends on the type and severity of the attack. After an attack of acute bronchitis of the larger tubes or mild lobar pneumonia, a child of 3 may be allowed to walk about the cot two or three days after the temperature is normal. A child of 12 should stay in bed ten days after mild lobar pneumonia. The severity of the attack being equal, the length of time spent in bed after the temperature is normal should vary directly with the size and age. After broncho-pneumonia convalescence is much slower and depends on the amount of permanent damage to the lung.

late Resident Assistant Physician to
St. Thomas's Hospital.

Special Articles.

SCHOOL EXCLUSION AND CLOSURE FOR INFECTIOUS DISEASE.

A MEMORANDUM on Closure of and Exclusion from School was first issued by the Board of Education in 1909, and a revised edition appeared in 1925 under the joint auspices of the Board and the Ministry of Health. The present reprint has been necessitated by the issue in 1926 of the revised Code of Regulations for Public Elementary Schools, and in January, 1927, of Administrative Memorandum No. 51, in which is laid down the principle that if, during epidemics of infectious disease, the power to exclude individual children from school be used to the best advantage, it is only in special and quite exceptional circumstances that it will be necessary to close a school in the interests of public health. Experience of the last 15 years strengthens this view, although until this year it was possible for local education authorities to close schools during the prevalence of epidemics of infectious disease not purely in the interests of public health, but on financial grounds, in order to prevent loss of grants owing to the lowered attendance of children at such times. The Board and the Ministry will no longer accept the closure of schools for medical reasons unless such closure is in strict compliance with the principles laid down in this Memorandum.

The present Memorandum deals primarily with the closure of public elementary schools and the exclusion of individual children from such schools on account of infectious disease, but the provisions apply with modifications to special schools and institutions receiving grants. In the case of secondary schools, in which the problems of infectious disease seldom arise in an acute form, the Memorandum anticipates that the governing bodies and heads will be fully alive to the importance of the subject.

Parts I. and II. of the Memorandum deal with the powers of local sanitary and education authorities and their coördination. Part III. deals with the collection of information by various groups of staff officers and the part played by early recognition in the prevention of spread. In Part IV. are set out the general considerations as to the action to be taken in respect of infectious diseases—on this comment is made in our leading article. Part V. enumerates the rules for action in respect of particular diseases. This part is reproduced here substantially at length along with a table of incubation and exclusion periods of the commoner infectious diseases, which will be of value to all practitioners.

RULES FOR ACTION IN RESPECT OF PARTICULAR DISEASES.

The diseases for the prevention of which the exclusion of particular children from school or school closure may be required are principally those which spread by infection directly from person to person, such as measles, whooping-cough, scarlet fever, diphtheria, epidemic influenza, small-pox, chicken-pox, and rubella (German measles). In rare cases the same measures may be necessary for enteric fever and diarrhœal diseases, when these spread through local agency, such as infected school privies.

In the light of the general principles already set out the following procedure is suggested in order to enable the medical officer of health or the school medical officer to advise as to the minimum duration of exclusion of school-children which can with reasonable safety be adopted in the several more common infectious diseases. The recommendations made are subject to the proviso that each case, as it occurs, requires and should receive individual consideration.

Scarlet Fever.

Exclusion of Cases.—When treated in the isolation hospital he is usually detained for about six weeks,

and longer if any discharges continue from ear, nose, or throat. After return home, in view of the occasional protracted infectiousness of patients with such discharges, and sometimes even of those without them, the child should not return to school for two weeks, and a notice should be sent to the teacher and another to the parent to this effect. Wherever practicable, however, the child should be examined by the school medical officer or by an experienced health visitor or school nurse before readmission to school, and where this practice is followed it may be permissible for a child, free from any sign of infection, to return at the expiry of one week.

When the patient has been treated at home similar rules apply, provided that the patient and his rooms have been effectively disinfected after the illness has ended.

Exclusion of Contacts.—If the patient has been removed to the isolation hospital the teacher and the parents should be instructed to keep children living in the same house away from school for a period of one week from the day on which disinfection, subsequent to the removal of the patient, has taken place, and the parents should be instructed to keep these children out of contact with other children for the same period. An exception to this rule may be made for those children in respect of whom the school medical officer has satisfied himself, directly or through the medical officer of health, that they have already had the disease; such children may be allowed to return immediately after disinfection of the premises.

If the patient is treated at home no other children from the same house should attend school while the patient is infectious, nor for one week after the end of his period of isolation.

School Closure.—If there is active coöperation between the school attendance officers and teachers and the medical officer of health school closure should only exceptionally be needed for scarlet fever. In school this disease usually spreads slowly from child to child, and not in the explosive manner characteristic of measles. Hence diligent search for slight cases and supervision of "contacts" should in most instances render school closure needless.

Diphtheria.

Exclusion of Cases.—Whether treated in the isolation hospital or at home it is the practice in some districts to regard the patient as in an infective condition until three successive swabs taken on different days have given consistent negative results. These swabs should not be taken until at least 48 hours have elapsed since the last application of any disinfectant to the throat.

In certain hospitals it is now the practice to rely upon the complete recovery of a patient from all clinical symptoms of the disease rather than upon bacteriological methods, and the experience of these hospitals seems to show that by such means the spread of infection can usually be avoided.

In view of the debility left by an attack of diphtheria, return to school should usually be deferred for two or three weeks or longer, at the discretion of the medical officer, after the end of the attack, as determined by bacteriological or clinical methods.

Exclusion of Contacts.—Contacts in respect of whom positive swabs have been obtained should, as a general rule, be excluded from school until two or three successive swabs give negative results. If circumstances permit tests for virulence may be employed, and this should always be done, if possible, in cases where the bacilli persist for long periods without any signs of disease. If the organism has been shown to be non-virulent a child may be dealt with as though the swab were negative.

When the patient has been removed to the isolation hospital the children in the same house should be kept away from school for two weeks. During this period they should be closely watched for any signs of diphtheria developing, and should only be readmitted after a final careful clinical examination, which should be supplemented by the taking of a swab, with negative result. In the case of a child free from any signs of disease the period of two weeks may be shortened at the discretion of the medical officer when bacteriological examinations have been made with negative result.

When the patient is treated at home no other child from the same house should attend school while the patient is infectious, nor for ten days afterwards. This period must be extended in the case of children suffering from sore throat, sore nose, or any other signs of possible infectivity until a bacteriological report establishes their non-diphtherial nature. In exceptional cases, where complete isolation can be procured, contacts may be dealt with as though the patient had been removed to hospital.

School Closure.—Although diphtheria, like scarlet fever, and unlike measles, usually spreads comparatively slowly in schools, it is apt to be very persistent, and not infrequently causes serious mortality, especially among children under 5 years old. For these reasons, when cases of this disease occur in an infant school, there should be no hesitation in excluding children from attendance who are below the age of compulsory school attendance. Closure of a school or department is only justifiable when the precautionary measures detailed in the preceding paragraphs have failed to arrest the spread.

The need for protracted exclusion from school of recent diphtheria patients has already been emphasised. The systematic use of these measures should obviate the need for school closure for diphtheria.

Measles.

Exclusion of Cases.—Children attacked by measles should be kept from school for three weeks from the first appearance of the rash. This period should be extended if there are complications or sequelæ.

Exclusion of Contacts.—In large towns, and in the smaller districts in which the majority of children over seven years of age who are attending public elementary schools have had measles, the practice is frequently adopted, when measles breaks out in a household, of excluding from school attendance only those children of the same household who attend the infant school, and those older children of the same household who have not had measles. These particular children of the same household should be excluded from school until 21 days from the date of onset of the illness of the last patient with measles in the house.

The above procedure can be recommended, as the result of experience in large districts, to be worthy of general adoption; but it may need to be modified in accordance with the special circumstances of a district, particularly with reference to its past history as to measles. In order that the procedure may be efficiently carried out, it is very desirable that the past history of every child in regard to infectious disease, as recorded on the medical inspection card, should be tabulated, and that the table so obtained should be kept up to date in each class, and readily available for the purpose of determining, when a case of measles occurs, which children should, and which should not, be excluded from attendance at school.

School Closure.—Although school closure has been, and is still being adopted more frequently on account of epidemics of measles than for any other disease, there is a general consensus of opinion that except in the case of scattered rural populations, it is useless as a means of checking the spread of the disease. As a rule closure is deferred until a large proportion of the children are already absent, but even in those cases where early class closure has been attempted after the occurrence of a single case, experience appears to show that the only effect is to postpone and prolong the epidemic. It appears certain that in populous districts school closure for measles has but little value as a public health measure.

In thinly populated districts, where the homes are comparatively isolated, and children have long distances to come to school, school closure may, on the other hand, have a very definite value in preventing the spread of measles from one village to another,

and in reducing the risk of exposure to bad weather of those children who are already in the early stages.

German Measles.

In this mild disease (rubella, röteln) children need not be excluded from school for more than a week, dating from the first appearance of the rash. Immediate child-contacts in the home who have not had German measles should be excluded from school for three weeks from date of last exposure to infection by a patient in the eruptive stage.

Whooping-cough.

The rules as to exclusion from or closure of school for this disease should be similar to those for measles, except that the infection of whooping-cough probably lasts six weeks, and the children in the house who attend the infant school should be excluded from school for this period—or as long as cough continues.

Small-pox.

Children suffering from small-pox should be excluded until all scabs and "seeds" have disappeared. All contacts should be vaccinated or revaccinated, and should be kept under medical observation for a period of 16 days; for this purpose exclusion of contacts from school is not generally necessary or desirable.

Chicken-pox.

Children suffering from this disease should be excluded for three weeks or until all scabs have disappeared. The possibility of small-pox should always be kept in mind, and inquiry should be made in all instances as to the state of vaccination of supposed cases of chicken-pox. Infants, and other children who have not had chicken-pox, should be excluded from school for three weeks from the date of the last exposure to infection.

Mumps.

Children suffering from mumps should be excluded and not readmitted until one week after the subsidence of the swelling. In this disease, owing to its character and long incubation period, exclusion may, as a rule, be confined to the patient himself.

Influenza.

Children showing symptoms of influenza should be excluded from school during the period of attack, and should not be readmitted until a careful medical examination of the heart and lungs has been made to eliminate possible latent complications and sequelæ. In epidemics of influenza closure of schools may be employed occasionally with advantage, particularly in rural and small urban districts where the excluded children have few opportunities of coming in contact with each other outside the school.

Tuberculosis.

Pulmonary tuberculosis in a recognisable form is seldom a large factor in school life. Children known to be suffering from this disease should, at the discretion of the school medical officer, be excluded from school. All cases of open tuberculosis other than pulmonary should of course be excluded.

Epidemic Nervous Diseases.

Cerebro-spinal Fever.—A child suffering from cerebro-spinal fever will not even in favourable circumstances be in a fit state of health to attend school until three months have elapsed from the onset of the illness. Immediately the disease is recognised in a school the class-contacts should be kept under close medical observation for two weeks. If it can be arranged, such contacts should be accommodated in open-air classes. Home-contacts should be excluded from school for a period of three weeks. The disease has a high degree of fatality; in the event of recovery, sequelæ are not often present. Some patients display mental instability and irritability of temper, and it is desirable that all such cases should be kept under special medical observation for a year.

Acute Poliomyelitis.—The incubation period is usually placed at from two to ten days, the average period being three to four days. A child developing the disease should forthwith be excluded from school. If the paralytic signs are absent or extremely slight, and the general health is good, the child may be readmitted to school at the expiration of six weeks. Careful watch should be maintained in non-paralytic cases for the supervention of paralysis, as recurrent cases occur in which the paralysis is manifested after the acute symptoms have subsided. Paralytic cases will require a much longer period of school exclusion, and are afterwards better treated, if practicable, in special orthopædic institutions.

In times of epidemic prevalence, exclusion of all children in a particular class, closure of infant departments, and even of the whole school, may be required. It is highly important in epidemic periods to recognise mild and abortive cases of poliomyelitis, as they are largely instrumental in spreading the disease. The class-contacts of a child suffering from poliomyelitis should be carefully examined from this point of view, and any such child showing symptoms of gastro-intestinal disorder (vomiting, mild diarrhœa, &c.), catarrh of the upper respiratory passages, or muscular twitchings or neuritic pains should be regarded provisionally with suspicion, and should be kept under supervision and, if necessary, excluded from school. Home-contacts should be excluded from school for a minimum period of three weeks.

Encephalitis Lethargica.—If the disease develops in a school the child should at once be sent home, and care be taken to see that it is receiving suitable medical care in hospital or otherwise. Search should be made for school-contacts of the case. These contacts should be medically examined and watched. Any child exhibiting signs and symptoms suggestive of mild or abortive encephalitis lethargica should be excluded from school for a minimum period of six weeks.

Home-contacts in the affected household should be kept from school for three weeks after the isolation of the patient. Children who have suffered from the disease take a long time to recuperate, and they should not be allowed to resume school attendance until a careful medical examination pronounces the general health completely restored. In favourable circumstances a child may be permitted to resume school after the lapse of six months from the time of school exclusion; in many instances this period has to be extended to a year or even longer.

All children who have suffered from epidemic encephalitis, whether in the abortive, mild, or severe forms of the disease, should be kept under careful medical observation for a period of two years after the attack, as sequelæ may appear at any time within this period. The more important of these after-effects may include mental symptoms, symptomatic paralysis agitans, excito-motor sequelæ, and various sensory conditions. As a rule, children showing after-effects, unless in the mildest possible degree, should be excluded altogether from school, partly for their own sake and partly on account of the effect upon other children.

Enteric Fever and Erysipelas.

Children coming from houses in which have occurred cases of erysipelas or of enteric (typhoid) fever, who are not themselves ill, need not as a rule be excluded from school. Nor is school closure required for either of these diseases, except in the rare instances in which enteric fever is due to some condition directly connected with the school.

INCUBATION AND EXCLUSION PERIODS.

In an appendix is given a table of the incubation and exclusion periods for the commoner infectious diseases. It should be understood, when this table is used, that infectious disease is a process, not an entity, and that the process is liable to modification by many circumstances, such as the intensity of the infection, and the condition and resistant power of the body. The periods indicated in the second and

third columns of this table should therefore be regarded as approximate only.

Disease.	Incubation period (in days).	Interval (in days) between onset of illness and appearance of rash.	Period of exclusion.	
			Patients.	Contacts.
Scarlet fever.	1–8	1–2	Two weeks after return from hospital, or, in the case of patients treated at home, two weeks after release from isolation.	One week after removal of patient to hospital, or, in in the case of patients at home, one week after release from isolation.
Diphtheria.	2–10	—	Two to three weeks after end of attack; or until pronounced free from infection by a medical practitioner.	Two weeks after removal of patient to hospital, or, in the case of patients treated at home, ten days after release from isolation. Negative swabs should be obtained.
Measles	7–14	4	Three weeks from date of appearance of rash.	Infants, and other children who have not had the disease, three weeks from date of onset of last case in house.
German measles	5–21	0–2	One week from date of appearance of rash.	Infants, and other children who have not had the disease, three weeks from date of last exposure to patient with rash.
Whooping cough.	6–18	—	Six weeks from commencement of cough.	Infants only, for six weeks from date of onset of last case, or three weeks from date of last exposure to infection.
Mumps.	12–23	—	Until one week after subsidence of swelling.	No exclusion.
Chicken-pox.	11–21	0–2	Three weeks, or until all scabs have disappeared.	Infants, and other children who have not had the disease, three weeks from date of last exposure to infection.
Small-pox.	10–14*	3	Six weeks, or until the patient is certified free from infection by a medical practitioner.	Sixteen days, unless recently vaccinated, when exclusion is unnecessary.

* Usually 12 days.

SELBY WAR MEMORIAL HOSPITAL. — Viscount Lascelles last week opened this hospital of 20 beds which has cost, with equipment, £16,000.

COUNTY CLARE HOSPITALS "FALLING DOWN."—Commenting upon the recommendation of the Poor-law Commission of the Irish Free State that Boards of Health should be abolished, Mr. E. F. Kerin, chairman of the Clare County Board of Health, states that "all the hospitals in this county are falling down." He adds that "in the Kilrush District Hospital and the County Nursery rain is falling on the beds of the patients, slates are off, windows broken, and draughts whistle through every corridor." In the County Home at Ennis nearly 120 imbeciles are "packed together in shocking conditions."

HEREFORDSHIRE GENERAL HOSPITAL.—This institution is to be enlarged from 124 to 160 beds. The building, which dates from 1776, is in many respects archaic; the fittings and amenities are entirely out of date. It is proposed to provide a new surgical wing, a maternity unit, isolation and pathological blocks, and a new out-patients' department, and to make other enlargements and improvements. The scheme is estimated to cost nearly £75,000 and an appeal, addressed especially to Herefordians, has been launched. The chairman of the appeal committee is Lieut.-Colonel J. C. Sleeman, who may be addressed at the hospital.

THE PROBLEM OF VENEREAL DISEASE.

IMPERIAL SOCIAL HYGIENE CONGRESS.

WESTMINSTER, OCT. 3RD–7TH.

(*Concluded from page 784.*)

ON Friday, Oct. 7th, the chair was taken by Dr. T. F. DEWAR (Scottish Board of Health), and the subject of discussion was the

Administrative Aspect of Social Hygiene.

The Chairman reviewed the peculiar difficulties of Scotland and the work done there. The thorough education of general practitioners, he said, seemed the only way of reaching the scattered populations of the hills. There was in the north a very strong body of opinion in favour of extended legal powers, and this group included all the medical officers engaged in clinical venereal disease work and the representatives of the five predominant areas of population. The Board of Health were considering this need for further power very cautiously and very earnestly, especially with reference to congenital syphilis. It seemed monstrous that the parents of a syphilitic child should be allowed to go on producing infected children. He recalled the elaborate procedure brought into force by a case of small-pox, which had originally received its name because it was, indeed, a "small" scourge compared with syphilis, the "great pox."

Dr. J. R. KAYE (West Riding) explored the possibilities of new ideas in the prevention of venereal diseases, not only as a patriotic necessity but as a public health problem and an issue of the first importance. It was, he said, only when venereal diseases were faced as a public health problem and discussed impersonally that any progress could be made. It was chiefly from this angle also that the carrier could be eliminated. The present machinery was quite inadequate for gonorrhœa, and, although most syphilitic patients had been rendered at least non-infective, gonorrhœal patients who did not finally drift to the clinic far too often became chronic invalids. Where hospitals were not available, effective measures could best be accomplished by utilising centres in large towns by agreement between local authorities. In rural districts remote from a venereal disease centre women and children could be treated for syphilis at a child welfare centre, but it was impossible so to treat gonorrhœa. One solution was to provide beds for these patients in infectious diseases hospitals, and this would probably be economical in the long run, as the time of treatment would be shortened by many months.

Every effort should be made to trace patients and contacts and bring them under treatment and supervision. Married women suffering from gonorrhœa, according to report, showed a striking increase in 1925, and difficulties in the way of treatment were great. Even if the woman was aware of her condition and was willing to be treated, the fear of neighbours' comments, the difficulty of leaving children, and the time away from a busy home seemed to make it impossible. One solution was to have clinics open for admission at any time of the day, or to give facilities at child welfare centres.

Instruction to the general public must be placed first and foremost. The public should realise that the evils of misconduct were not confined to the individual himself, but were an injury to the community, anti-social conduct, and a potential source of danger to society. Education was not alone for the infected. What was wanted was a racial conscience, and a recognition that to keep fit is as much in the interest of the nation as of the individual. It was horrible to learn that 25 males and 475 females under 14 years suffered from gonorrhœa in 1925. There was no reason why sex physiology should not be taught by a trained person to all scholars over 13 years of age. All great social problems were in the end educational problems. Recreation also was very important. By coming to a clinic for treatment

a patient became a party to an agreement to continue treatment, and if he did not do so any method of inducing or compelling him was justifiable. Some means such as notification, and if necessary threatened publicity, was indicated, particularly when the lapse might mean the infection of others. The advantages were on the side of compulsory notification, but it was admitted by all that the best way was sex morality and higher ideals. The only true prophylaxis in the congenital treatment of all cases was the prohibition of marriage until a probable cure had been effected.

Dr. Kaye concluded: "After reasoned consideration of all other measures, I am of opinion that a mighty gap in our efforts would be filled up if it was penal for any person suffering from a contagious disease of the sexual organs knowingly to endanger or infect a person of the opposite sex. Such a power would render isolation really unnecessary . . . Refusal to be examined would be tantamount to acknowledgment of the existence of disease and afford prima facie evidence that a person is infected. I would not limit the suspect to any type, but to those reasonably suspected and believed to be suffering, for the clandestine, and, unfortunately, the married, are now regarded as disseminators of infection not less than the prostitute."

Dr. A. S. M. MACGREGOR read a paper on the

Powers and Responsibilities of Local Authorities in the Venereal Diseases Campaign.

He reviewed the powers conferred on local authorities in 1916 and the work done in Glasgow, where it had been found that the isolated ad hoc clinic was as successful as that conducted at a general hospital. For mothers and young children, however, it had been found essential to provide facilities for venereal disease treatment at antenatal and infant consultation centres. As schemes had been perfected, he said, the inherent weakness of the voluntary system had become apparent, and Glasgow was all in favour of compulsory notification. The number of patients who stopped attending a centre as soon as their symptoms had been alleviated was never less than a quarter of the total, and a sense of futility very naturally arose in the minds of the medical and administrative officers of these clinics. The figures from the Glasgow city clinics showed that, while half the men ceased attendance before the end of their first course of treatment, only 10 per cent. of women defaulted. The appointment of a special nurse to "follow up" women and children had been attended by some success, but was far from solving the problem. The principal causes of defaulting were indifference and carelessness, and in the great majority of cases a hint of the existence of power to enforce treatment would be sufficient. Local government in this country could now be trusted to use such powers judiciously and temperately. To the various objections raised by the opponents of compulsion there could be no answer but a trial. Matters could not be allowed to remain as they were. As a basis for discussion Dr. MacGregor laid down suggestions which ensured the treatment of parents of infected children and secured the compulsion of defaulters, removing them to hospital, if necessary, on a magistrate's order.

Dr. T. FERGUSON (Darlington) read a paper on

Congenital Syphilis as a Public Health Problem.

He gave figures illustrating the grave problem presented by congenital syphilis, its mortality and morbidity, and the drain it inflicted on institutional accommodation. The importance of early systematic treatment, he said, was only equalled by the importance of continuing to a final cure. This might very often need five years of supervision. The ideal method of dealing with congenital syphilis was to prevent it by the adequate treatment of acquired syphilis. Failing that, the strongest weapon was early treatment of the expectant mother. Every antenatal examination should include a search for venereal disease, as a missed diagnosis at that stage might easily cost an infant life. Routine coöperation between treatment centre and antenatal clinic was absolutely essential, and it was well for a syphilologist to attend the welfare centre. Another useful routine was the examination of blood from the umbilical cord at birth by the Wassermann test. Children reaching the venereal disease centre through the general medical practitioner, the hospital, and the school clinic generally arrived too late. The number of untreated syphilitics in the school population was alarming, and most of them had developed intractable lesions by the time they were seen. Collaboration between the V.D. officer and the school medical service was vital, and should be directed chiefly towards examining new entrants and children at nursery schools. In county boroughs the services of the venereal diseases officer were best made available by appointing him a part-time member of the school medical staff. The congenital syphilitic was as likely to deteriorate as the tuberculous child, and after-care could not be neglected. It was best given by the health visitor. A certain number of children needed in-treatment and an open-air régime for many months, and could be provided for in small annexes to existing sanatoriums. Syphilis when tackled early was an eminently curable disease.

Dr. R. FORGAN (Lanark) suggested as measures, short of compulsion: (1) compulsory notification of pregnancy; (2) universal compulsory certificate of health for marriage; (3) schemes for filling the most important gap between the infant welfare doctor and the school medical officer; (4) more thorough examination and treatment of prisoners; (5) more stringent control of mental defectives and moral imbeciles; (6) careful watch over soldiers and sailors; and (7) the legalisation of the sale of ad hoc disinfectants. He wished, however, to lay chief stress on the tremendous power and responsibility of the general medical practitioners. Many of them were very inadequately trained in the modern treatment of venereal disease, and it was said that they would resist any attempt to put their patients under specialist care. The working man was often said to be misrepresented by his trade-union officials and to be a perfectly reasonable person in reality. It might be well to ask the practitioner himself what he thought about the matter, and not to take the unsupported word of the British Medical Association. He had sent out a questionaire to practitioners in Lanarkshire and had had 104 replies. Of these, five were satisfied with present arrangements, four were against compulsory treatment, four were in favour of compulsion but objected to sending their cases on to specialists, and 91 approved of a scheme of modified notification and compulsory treatment by a special panel of doctors. Of these 91, 52 did not wish to treat their patients for venereal disease and were quite willing to pass them on, and 39 expressed a wish to serve themselves on the special panel. He suggested that these figures might prove representative of the medical profession throughout the country.

Miss ALISON NEILSON put the case for the non-compulsionist, maintaining that the experience of other countries showed that its results were no better than those of our present voluntary confidential scheme, which would be gravely prejudiced by the introduction of notification.

Dr. F. ROBINSON (Cambridge) spoke of the difficulties of the rural area, where the essential privacy in treatment was impossible unless the V.D. officer could visit the patients in their homes or attend at infant welfare centres.

Dr. C. L. PARK (Australia) and Mr. A. MOORE (London) maintained that compulsory notification in the colonies had been a success, provided the cases were followed up.—Mrs. SOMERVILLE (Edinburgh) was also in favour of compulsory notification, and pleaded for the establishment of toddlers' playrooms, open at least two hours a day. They were very cheap to run, and there the small children could be taught good habits and self-restraint, given air and exercise and provided with medical examination, making

continuity between the infant care centre and the school. Edinburgh had ten of these playrooms.

Dr. W. G. SAVAGE (Somerset) described the successful scheme tried in his district, whereby the school medical officers were trained in venereal disease and were able to take country clinics without bearing the stigma of "V.D." He was in favour of compulsion provided it was kept entirely on public health grounds. On those terms the public would put up with a great deal, he thought.

Mrs. NEVILLE ROLFE did not think this country had yet reached the time when a compulsory system could be instituted without rousing a storm of protest. Such a psychological reaction would completely vitiate the good that might be done and destroy all the atmosphere of confidence which had been so patiently built up.

LONDON MEDICAL EXHIBITION.

(*Concluded from p. 786.*)

LAST week we gave a brief summary of many of the drugs and pharmaceutical preparations shown at the London Medical Exhibition, which was held from Oct. 3rd to 7th. Below will be found notes of other important exhibits.

SURGICAL INSTRUMENTS.

ALLEN AND HANBURYS, LTD. (37, Lombard-street, London), had a large display of surgical instruments mostly in stainless steel. Particular attention was drawn to the St. Bartholomew's Hospital pattern operation table with a new patent skull support, and to an antrum illuminator, an instrument for the injection method in the treatment of hæmorrhoids, and gynæcological and obstetrical instruments. Of interest also was the "Metalix" Hot Cathode X ray tubes shown by this firm, the general construction of which embodies a covering of lead in order to protect the operator.—DOWN BROS., LTD. (21 and 23, St. Thomas's-street, London), showed many forms of surgical instruments and appliances. —One of the features of the stall of MAYER AND PHELPS (Chiron House, 59–61, New Cavendish-street, London) was the Chiron Chloroform Inhaler which eliminates the possibility of pumping out liquid chloroform either by wrongful attachment of bellows or by overfilling, while there are no valves to get out of order. Instruments and apparatus in stainless steel for general and regional surgery were displayed, as well as aseptic hospital furniture.—SURGICAL MANUFACTURING CO., LTD. (83–85, Mortimer-street, London), exhibited instruments of all kinds for surgical use.—HOLBORN SURGICAL INSTRUMENT CO., LTD. (26, Thavies Inn, Holborn Circus, London), presented an attractive display of surgical instruments and called particular attention to French's Blood Aspiration Set and Needle, Blair Bell's Vulva Retractor, and Harrison's Urethroscope. May's Electric Ophthalmoscope was also shown.—MEDICAL SUPPLY ASSOCIATION, LTD. (167–185, Gray's Inn-road, London), had a large exhibit of ultra-violet radiation apparatus, X ray apparatus, and surgical instruments and hospital furniture.—BRITISH HANOVIA QUARTZ LAMP CO., LTD. (Slough, Bucks), showed several models of their well-known lamps for ultra-violet therapy which can be supplied for either direct or alternating current, as well as the Jesionek Quartz Lamp for the irradiation of several patients at the same time, and the Hanovia Sollux Lamps for hyperæmia therapy.—I. CALVETE, LTD. (11, Little St. Andrew-street, Charing Cross-road, London), exhibited electro-medical apparatus, including the Solart ultra-violet carbon-arc lamp, the Icalite infra-red ray therapy lamp, and the Everay high-frequency generators. Diathermy, ionic, galvanic, and faradic apparatus were also shown.—ELECTRICAL EQUIPMENT AND CARBON CO., LTD. (Bank Buildings, 109–111, New Oxford-street, London), showed many forms of Siemen's carbons for therapeutical purposes. Some 20 different brands of these carbons were exhibited including those cored with tungsten, thorium, or iron, particular attention being drawn to the absence of sputtering in the working of the latter. Much interest was manifested in the demonstrations showing the spectrum of the arc by means of a Beck spectroscope, a new model 10-amp. Westminster arc lamp being used.—BRUCE, GREEN AND CO., LTD. (14–18, Bloomsbury-street, London), makers of medical and electrical appliances and ophthalmic instruments for ophthalmic work, made a special feature of their combination set for the examination of eye or nose and throat with detachable sterilisable tray, and demonstrated an attachment by which any type of vaginal speculum may be illuminated. This little apparatus is easily detachable for sterilisation.

R. H. DENT (309, Oxford-street, London) showed "Ardente" Aids for the deaf, many of them being of ingenious design, unobtrusive in appearance, and possessing excellent tonal qualities. A special feature of this stand was the stethoscope for deaf practitioners which the firm state is the only one made.—GENERAL ACOUSTICS, LTD. (Acousticon House, 77, Wigmore-street, London), among a large number of appliances for the deaf, showed the "Shellacon" microphone which can be worn under the clothing and so be out of sight; a miniature ear-piece and a midget battery, the total weight being only a few ounces, completes a very useful appliance. A large and more powerful ear-piece is made for use in theatres and public halls.—W. H. PETTIFOR (11, Victoria-street, London) presented a wide range of electrical aids for the deaf, and ACOUSTIC SUPPLY CO., LTD. (3–4, Eden-street, London), also showed appliances for the deaf. —H. E. CURTIS AND SONS, LTD. (7, Mandeville-place, London), manufacturers and designers of abdominal belts, trusses, and elastic hosiery, showed their abdominal support for the treatment of ptosis, the protection of abdominal scar tissue during consolidation, for mobile or displaced kidney, and for varying forms of umbilical and ventral hernia as well as a colostomy support and improved trusses of various kinds.—DOMEN BELTS CO., LTD. (456, Strand, London), also showed many forms of belts designed on physiological and anatomical lines, including belts for pregnancy, accouchement and general support, gastroptosis, umbilical hernia, and floating kidney.

INHALING DRUG AND APPARATUS CO., LTD. (30, Grosvenor-place, London), made a special feature of the Apneu Spiess-Drager Drug Nebulising and Inhaling Apparatus, the diameter of the vapour particles measuring approximately from 5 to 10 μ. By the use of the apparatus aqueous or oil vapour may be inhaled separately and their flow and density can be regulated with great precision.—G. H. ZEAL, LTD. (75–77, St. John-street, Clerkenwell, London), showed many forms of useful clinical thermometers, and SHORT AND MASON, LTD. (Macdonald-road, Walthamstow, London), showed sphygmomanometers, clinical thermometers, recording thermometers, and the Tycos Barograph, which records the most minute changes of atmospheric pressure.—KODAK, LTD. (Kingsway, London), showed an interesting display of X ray materials and accessories, including Dupli-Tized X ray film, developing tanks, intensifying screens, and the Kodak X ray reduction camera. Dental X ray negative specimens illustrating the "Bite Wing" system for early detection of interproximal cavities and negatives were exhibited, as well as an X ray angle tilting board designed to provide cassette support at a definite angle for simplifying the positioning in extra oral radiography of the lower jaw, and to facilitate correct and uniform delineation of the frontal sinus and mastoids without tilting the tube.

FOOD AND MILK PRODUCTS.

Milk and milk products were admirably displayed by GLAXO (56, Osnaburgh-street, London), who also showed Ostelin, a physiologically tested preparation of the essential vitamin of cod-liver oil—vitamin D. Ostelin in glycerine, Ostelin with malt extract and

orange-juice, and Ostelin tablets as well as Ostelin cream containing Ostelin equivalent to 50 per cent. cod-liver oil were also shown.—WEST SURREY CENTRAL DAIRY CO. (Cow and Gate House, Guildford, Surrey), the manufacturers of Cow and Gate Milk Food, demonstrated the therapeutic value of Brestol, a humanised cream which contains the growth-promoting and antirachitic vitamin (cod-liver oil source) and the antiscorbutic vitamin (orange-juice source). Lacidac, a lactic acid milk powder, was another exhibit of this firm which drew much favourable comment.—TRUFOOD, LTD. (Lever House, Blackfriars, London), who specialise in the manufacture of pure milk products, showed their Trufood Full Cream for use from 9 months onwards, for nursing and expectant mothers and for invalids, and Secway, a pure, sweet whey powder.—HORLICK'S MALTED MILK CO., LTD. (Slough, Bucks), exhibited a full-cream milk combined and modified with soluble extracts of malted barley with a high vitamin content. A teat specially designed to use with the 2*s.* size of a malted milk bottle, thus converting it into a feeder, attracted much attention.—MEAD'S INFANT DIET MATERIALS (Brooks and Warburton, 40–42, Lexington-street, London). Recolac, a reconstructed milk food for infants; Casec, a corrective diet for green fermentative diarrhœas, wind and colic, and cœliac disease; Dextri-Maltose, for modifying cow's milk for infants as well as a modified lactic acid milk in dried form, and a standardised cod-liver oil.—THE MALTINE MANUFACTURING CO., LTD. (23, Longford-street, London), showed their products, including Malto-Yerbine, containing the active principle of Yerba Santa (*Eriodictyon californicum*) for the treatment of bronchial conditions.—BOVRIL, LTD. (148–166, Old-street, London), displayed the well-known preparations which can be used in combination with milk and with cod-liver oil.—VITALIA, LTD. (17A, Boniface-street, Westminster Bridge-road, London), showed their meat juice prepared by a cold process, thus retaining the natural vitamins and organic salts. This preparation contains 8 per cent. of hæmoglobin and is a rapidly acting tonic where indicated.—OXO, LTD. (Thames House, Queen-street-place, London), presented their meat juice, an invalid preparation which is produced by a special process which preserves the soluble proteids of the juice in their natural uncoagulated condition, thus providing a nourishing and strengthening food of high tonic quality, especially suitable when the appetite is feeble and solid foods cannot be assimilated. Included among the Oxo products were their well-known Hospital Oxo, Lemco, Beef Essence, and the "Oxoid" Endocrine Preparations for use in glandular therapy.—VIROL, LTD. (Hanger-lane, Ealing, London), showed Virol, a scientifically prepared food to meet the requirements of the growing age, together with Virol and Milk and Virolax, an emulsion of pure liquid paraffin.—VITMAR, LTD. (Callard's Vitamin Foods) (Southfields, London), called attention to their tonic food and to Cibrons, colloidal agar-agar with fruit juice for the treatment of constipation without drugs or paraffin.—ETAN LIQUEFIED FOOD (Agents: Dehez, Surbiton, Surrey, and Monument Buildings, London) showed their product consisting of the hydrolysates of animal albumins which is indicated in gastric disturbances, all forms of malnutrition, and in convalescence. The liquid is put up in bottles and is agreeable to the palate.—BRAND AND CO., LTD. (Mayfair Works, Vauxhall, London), exhibited Essences of Beef and Chicken, Meat Juice and Iron Tonic Food, as well as Liquid Peptone.—BATTLE CREEK FOOD CO., of which Coates and Cooper are the agents, demonstrated its system of biologic feeding, and exhibited Lacto Dextrin for changing the intestinal flora, Laxa, a laxative biscuit composed of agar-agar and cooked bran, Paramels, mineral oil in caramel form, and Food-Ferrin, a new iron food.—CADBURY BROS. (Bournville, Birmingham) showed their cocoa and chocolate.—J. E. AUSTIN AND CO., LTD. (St. James's Works, Cromwell-road, Kingston-on-Thames), showed sugarless jams and marmalade suitable for diabetes; the varieties include apricot, raspberry, green plum, red plum, and marmalade.

MISCELLANEOUS.

THE DENVER CHEMICAL MANUFACTURING CO. (London, E.) demonstrated their well-known Antiphlogistine, a hydroscopic antiseptic poultice for inflammatory and congestive conditions.—PASTILLES, LTD. (124, High-street, Shoreditch, London), showed the Lakerol Brand Bronchial Pastilles and other pastilles in great variety.—THE PINEOLEUM CO., INCORPORATED (Distributing Agents: Brooks and Warburton, 40–42, Lexington-street, London), exhibited this now well-known inhalant.—KOLYNOS, INCORPORATED (Chenies-street, London), showed their dental cream with a non-gritty content and antiseptic composition, Kolynos dental powder for artificial dentures, and Kolynos skin soap for toilet and nursery purposes.—KEEN, ROBINSON AND CO., LTD. (incorporated with J. and J. Colman, Ltd., London and Norwich), exhibited, in addition to many other preparations, Almata, a complete food for infants, invalids, and expectant and nursing mothers, put up in an ingenious air-tight tin which is opened by a special cutter contained in the lid. The lid also forms an air-tight covering after the tin is opened. The bath mustard made by this firm is now put up in a new packing, each packet containing sufficient to charge a full-sized bath.

JAEGER CO., LTD. (95, Milton-street, London), displayed a wide selection of pure wool underwear and outwear, rugs and footwear, as well as camel hair blankets. The advantages claimed for the wool clothing supplied by this firm is that it is a slow conductor, porous, and absorbent to moderate moisture.—SCHOLL MANUFACTURING CO. (Granville-square, London) had an interesting display of useful appliances for foot troubles.—GAS LIGHT AND COKE CO. (Horseferry-road, Westminster), in addition to demonstrating the advantages of gas-fires, showed how the contents of the dust-bin can be hygienically dealt with by means of a gas incinerator, the resulting ash forming a valuable fertiliser for the garden.—MEDICAL SICKNESS, ANNUITY AND LIFE ASSURANCE SOCIETY, LTD. (300, High Holborn, London), which is a mutual society of medical and dental practitioners, managed by members of the medical profession for the benefit of that profession, had attractive sickness and accident insurance and life assurance policies to explain to those interested, and set out the advantages of becoming a member of "Your Own Profession's Society."

SPAS AND WATERS.

Attractive displays were made by English spas—pictures, books, and pamphlets making vivid to the imagination the various treatments which these watering places afford and the places of interest in their vicinity. BATH emphasised the special treatments which are obtainable at this centre and called attention to the extensive new accommodation which has just been provided for the Plombiéres system of intestinal douching. The rebuilt Old Royal Baths were opened last month.—The BUXTON exhibit emphasised the advantages of its radio-active thermal waters, its peat baths, and electric treatment as well as its drinking cure from the spring which arises at St. Ann's Well where the water is drunk. This water can be obtained in bottles and siphons and makes a pleasant table water.—DROITWICH made prominent the analysis of its spring water which provides "a constant quantity of brine as clear as crystal," and "Wychia," a saline aperient and laxative water of which natural brine forms the basis.—The feature of the HARROGATE Spa is the system of training the staff at the bathing establishments who must pass an examination after two years' course of lectures and do 18 months' practical work before gaining the diplomas which all must hold. The waters are under the constant supervision of a permanent scientific officer.—It is announced that a complete geological survey of this spa is to be undertaken by Prof. Albert Gillagan, of Leeds University.

—TORQUAY, with its special treatments of hot sea water and seaweed baths, Dartmoor peat baths, and packs will shortly possess a magnificent sun lounge which will embody a vitaglass structure, 90 feet by 15 feet, fitted with the latest ultra-violet radiation apparatus. Its estimated cost is £3000.—INGRAM AND ROYLE, LTD. (Bangor Wharf, 45, Belvedere-road, London), who are importers and exporters of natural mineral waters, salts, and pastilles, presented a wide selection of waters, including those from three Vichy springs, and Evian-Cachat, Carlsbad, and Hunyadi Janos.

MEDICAL PUBLISHERS.

The following medical publishers showed a large assortment of books: ADLARD AND SON, LTD. (21, Hart-street, Bloomsbury-square, London, and Bartholomew Press, Dorking); WILLIAM HEINEMANN (MEDICAL BOOKS), LTD. (20, Bedford-street, London)—this firm also showed specimen tubes of vaccine lymph; BAILLIÈRE, TINDALL AND COX (7–8, Henrietta-street, London) who are agents for the Williams and Wilkins Co., of Baltimore; and H. K. LEWIS AND CO., LTD. (136 and 140, Gower-street, London), many inquiries being made regarding the medical and scientific circulating library of this latter firm.

A similar medical exhibition will be held in the Drill Hall, Burlington-street, Manchester, from Tuesday, Oct. 25th, to Friday, Oct. 28th, particulars of which can be obtained from the British and Colonial Druggist, Ltd., 194–200, Bishopsgate-street, E.C. 2.

THE MOTOR SHOW.

OLYMPIA, OCT. 16TH—22ND.

THE twenty-first annual motor show opened on Thursday, Oct. 13th, at Olympia. Three features distinguish the exhibition this year—incredibly low prices, the perfection of the covered bodies on the cheap cars, and the great increase in the number of small "sixes." The first is the result of ever-growing competition. The second is due to the development of the fabric saloon, a form of construction which originated in the aircraft industry. The body consists of a light frame of laminated wood, sometimes braced diagonally with wires, with a skin of leather or American cloth stretched over it. The frame is attached to the chassis on rubber buffers, and in some makes the seats are mounted separately and not connected with the body in any way. The result is that the body "gives" to the movements of the car and, since it has no weight to support, lasts a long time and is free from rattle. Its extreme lightness means a better performance and economy in running costs. Nevertheless, some buyers will always prefer metal panels, and the Morris, Citroën, and Austin cars show how good low-priced rigid bodies can be.

Cheaper Cars.

This year a dozen makers are showing saloon cars priced at under £200; two years ago there was only one. For those who do not want a permanent cover the same cars are available with two or four-seater bodies for correspondingly smaller sums. The Austin Seven is now down to £135, the Singer Junior two-seater to £140, the cheapest Morris and Clyno two-seaters to £152 10*s.* each, and the Jowett to £134. The Trojan can now be bought with a full saloon body for £170; the simplest model of this admirable car costs £125 only. Of last year's £100 cars only one has survived, the French three-cylinder air-cooled Lafitte. There are some very interesting newcomers under £200. The Standard Company are making another "Nine," the four-seater model of which is priced at £190. The Triumph Super-Seven tourer at £149 10*s.* and fabric saloon at £187 10*s.* will be a serious rival to the hitherto unique "Baby" Austin, if it is as good as every other Triumph model has been. An entirely new 9 h.p. Clyno is being shown at £145, with a four-seater fabric saloon at £160, and the other Clyno cars now have larger and differently shaped radiators and are improved in many ways.

Small "Sixes."

The doctor who goes to Olympia in search of a car of about £15 annual tax will find a range of choice fully ten times as wide and much more attractive than he would have found two years ago. The rise of this class has been phenomenal, and whereas in 1925 there was hardly a six-cylinder car of this size to be seen, now the "sixes" actually outnumber the "fours." He should be sure to see, for example, the Lea-Francis Six, costing, with the open five-seater body, £425; and the new Alvis Six at £595. Of the moderate priced American cars the most attractive are the Erskine (£17 tax) £325 saloon; the Essex Super-six (£18 tax) £245 saloon; and the Chrysler 21/60 at £385 for the saloon. The new Vauxhall 20/60 six-cylinder at £475 with a touring body, and the Armstrong-Siddeley 15 h.p. Six at the startling price of £400 with a fabric saloon are, however, splendid answers to the American challenge. The smallest of the "sixes" is the new Renault "Monasix," the tax on which is £13. With a four-seater body it costs only £279, and is the first low-priced "six" of this size on the market.

Among the most interesting newcomers to the largest class is the 30 h.p. 12-cylinder Daimler, a smaller edition of the 50 h.p. model which attracted so much attention last year; its chassis price is £1330. Bentley's are showing a 4½ litre four-cylinder car which costs £1295 with a touring body. German firms are exhibiting for the first time since the war, and the supercharged Mercédès 24/100 and 33/140 are fine specimens of the very fast and yet flexible touring cars at which these makers excel. Sunbeams are making two "straight eights," the chassis price of which is £1175 and £1375 respectively. Incidentally, the "straight eight" is not confined to the very expensive class, and examples of moderately priced cars with this type of engine are the 18 h.p. Beverley-Barnes (£675) saloon, the 17.8 h.p. Bugatti (£760) saloon, and the 21/60 Wolseley (£750) saloon.

The Final Choice.

Cars without four-wheel braking are now the exception rather than the rule, and semi-balloon tyres and shock absorbers are fitted even on the cheapest. Moreover, so reliable have engines become, and so well made is the coach-work, that the odds are two to one on the result of a blindfold choice being satisfactory. Nevertheless, the buyer should remember how important are small details. He cannot be certain that he is buying a car that will really content him unless he takes it out for a good trial run and satisfies himself that the springing is good over bad surfaces, that the mechanical noise is tolerable, that the controls, seats, and instruments are comfortably placed, that the doors are easy to open and pass through, and that the bodywork, especially on closed cars, does not rattle or admit weather or exhaust gas. How many buyers ask for a trial run at night to test the lighting apparatus? Yet for a doctor this is one of the most important parts of the car.

Finally, the visitor should remember that the best guide for a busy man is the special Show Number of one of the motor journals, such as the *Autocar*.

RECONSTRUCTION AT EDMONTON.—Proposals have been made for the reconstruction of the North Middlesex Hospital at a cost of £200,000.

SALARY OF CORONERS.—It was reported at a recent meeting of the Leeds Corporation Finance Committee that the Home Secretary had fixed the salary of the Leeds coroner at £1500 a year. The coroner had made application for a fixed salary of £1880 under the provisions of the Act of 1926. The Finance Committee had recommended that the salary should be £1350, and the matter had been referred to the Home Secretary, who, under the provisions of the Act, is empowered to fix the salary in cases where agreement cannot be reached locally.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Relief of the Poor in the Free State.

IN March, 1925, the Minister for Local Government and Public Health appointed a Commission to inquire into the laws and administration relating to the relief of the sick and destitute poor, and this Commission, of which Dr. T. Hennessy, T.D., was the only medical member, has now issued its report, which fills a bulky volume (Eason and Son, Dublin, 2*s.* 6*d.*). In the terms of reference particular attention is directed towards the adequacy of schemes formulated under the Local Government (Temporary Provisions) Act, 1923; the existing laws and practice as regards home assistance; the law and administration affecting the relief of widows and their children, children without parents, unmarried mothers and their children, and deserted children; the provision in public institutions for mentally defective persons; the area of chargeability on local rates of the destitute poor. There was no special reference in the terms to any matters directly concerning health, and the Commission appears to have interpreted its functions widely in giving as much attention as it has to the condition of the Poor-law hospitals and to the Poor-law medical service. At the same time it has exercised some caution in not trespassing too far on the ground covered by the Committee of Inquiry on National Health Insurance and the Medical Services, which submitted its final report a few months ago.[1] The Commission in the course of its investigations has covered a great deal of ground, and has perhaps attempted too much. It has interpreted its instruction to study the working of the scheme adopted in pursuance of the Act of 1923 as a direction to consider in detail the schemes actually at work in the 26 counties. It is clear that such a survey is bound to be superficial, and the detailed advice founded on it will be of little use. The Commission could have occupied its time better by devoting itself to more general considerations than by going over the ground ordinarily covered by the reports of the inspectors of the Department of Local Government and Public Health.

The report begins with a brief historical statement of the Poor-laws in Ireland, and more particularly of the changes that have taken place in the Irish Free State since its establishment, and an attempt is made to assess the success or failure of these recent changes. It is suggested that the closing of the workhouses and the removal of restrictions or the granting of home assistance (outdoor relief) has in some counties operated prejudicially to the interests of the poor, while the saving in cost has been negligible. In the summary given in the report it is stated :—

"In the county homes we found the following classes, whether the schemes contemplated their admission or not—viz., aged and infirm of both sexes; lunatics, idiots, and imbeciles of both sexes; unmarried mothers and their children, in some cases married mothers and their children, and orphan and deserted children. In a number of the homes there were cases of advanced tubercular diseases and also cases of cancer. The county homes are not fit and proper places for the reception of the various classes we have found in them, and therefore, in so far as the schemes, either through omission to make provision for or through actual commission in bringing together these classes, have conduced to that state of affairs, they must on that ground, if on no other, be deemed inadequate and unsatisfactory. The classes that should not be retained in the county homes and for which other provisions will, therefore, have to be made are as follows: Unmarried mothers, married mothers, children, and mental defectives. Reserved even for the aged and infirm poor and chronic invalids, the county homes, with one or two exceptions, require much structural alteration and improvement before they can be considered as coming up to the standard of comfort required."

In regard to the county hospitals it is stated that—

"In some counties the institutional accommodation provided for the sick falls far short of what the county scheme contemplates. The centres chosen for the county hospitals are, as a rule, suitable, but the hospitals themselves are not, in some instances, up to a reasonable standard, nor is the accommodation sufficient, while in others the development is taking place on lines that are not consistent with the general policy of complete severance from ordinary poor relief. The county hospital should be an institution under one control in which both medical and surgical cases are treated."

The retention of tuberculous cases in the county homes is condemned, and boards should be required to make arrangements for their institutional care in neighbouring counties where this is desirable.

The Commission is in favour of a scheme of mothers' pensions, payable by the State.

In regard to the dispensaries of the Poor-law Medical Service the criticism is made that the accommodation and equipment provided in some of them is unsuitable and the standard of cleanliness often very low. The tone of some of the references to the work of the dispensary medical officers appears to show an unexpected hostility, and criticisms are made for which no evidence beyond mere suspicion is forthcoming. For example, we find, without any reference to evidence, the statement :—

"We are aware that there exists among many of the small landholders of the west, some of whom on even a very restricted definition of poor person would be entitled to free medical attendance, a belief that they would not get proper attendance on a ticket, and this no doubt operates against the full use being made of the dispensary service as they endeavour, no matter how small their resources, to scrape together a fee for the doctor."

Again, without any reference to any suggestion from witnesses that medical officers are habitually or frequently lax in their duties, it is said: "The poor as a whole are very slow to make complaints; but because no complaints are made it does not follow that there are no grounds for complaint." It is surely going beyond the function of a Commission, in the absence of evidence, to evolve from their own minds the existence of abuses, in order to suggest remedies. It is no matter for wonder that Dr. Hennessy has thought it necessary, in a note appended to the report, to express his dissent from the paragraphs dealing with the dispensary service.

In discussing problems connected with unmarried mothers the Commission recommends that the age of consent should be raised to 18 if not to 19 years, that the law in regard to sexual offences should operate evenly against both sexes; and that all private maternity homes should be licensed annually.

The most important reform advised by the Commission is in regard to local administration. The report states :—

"While recognising that it is possible for a board of health under a capable and business-like chairman and with the help of committees to work the administrative machine efficiently, we are inclined to the view that in actual practice the Boards are not able to exercise the supervision which their institutions, officers, and services require. We are unable to formulate any plan which, by merely altering the constitution or methods of procedure of the Board, would be calculated to lead to more efficient administration.

"The alternative we recommend is the abolition of the Board of Health and the assumption by the County Council itself of the control of poor relief working through a paid official whom they would place in entire charge of the Poor-law services of the county in the same manner as the general manager of a company under the control of a board of directors."

Under this scheme the Commission believes it would be possible and desirable for the Central Authority to allow the county councils a very much freer hand than is allowed to the Board of Health.

Irish Free State Medical Council.

The following have been nominated to act on the Medical Registration Council of the Irish Free State under the Medical Practitioners Act, 1927 :—

By the Executive Council: Dr. H. F. Moore and Dr. J. N. Meenan.
By the Royal College of Surgeons: Sir Arthur Chance.
By the Royal College of Physicians: Dr. T. G. Moorhead.
By the Apothecaries Hall: Dr. E. Magennis.
By the Trinity College, Dublin: Prof. A. F. Dixon.

[1] See THE LANCET, July 23rd, p. 198.

By the University College, Dublin: Dr. D. J. Coffey.
By the Medical Practitioners of the Free State: Mr. Maurice Hayes and Dr. R. J. Rowlette.
The Council is to consist of 11 members, who will hold office for five years. The University Colleges of Cork and Galway have not yet nominated their representatives.

It will be noticed that there is a considerable overlapping as regards personnel between the Irish Council and the General Council, the following being members of both bodies: Sir Arthur Chance, Dr. Magennis, Prof. Dixon, and Dr. Coffey.

Royal College of Physicians of Ireland.

Dr. W. A. Winter was, on Oct. 7th, selected as candidate for the Presidency of the College, subject to election on St. Luke's Day. Dr. Winter is a graduate of Dublin University, and has been a Fellow of the College since 1901. He has served as examiner on several occasions, and has been censor and vice-president of the College. He is one of the physicians to Dr. Steevens' Hospital.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Duodenal Tube.

Dr. Pasteur Vallery-Radot and Dr. Blamoutier have studied in 22 cases of typical migraine the effect of treatment by the duodenal tube with drainage of the gall-bladder by means of 33 per cent. magnesium sulphate, according to the Melzer-Lyon technique. In seven of these cases the results were excellent. The usual practice was to pass the tube once a week for six or seven weeks, and some of the patients had no further attacks after the end of such a course. In other cases the migraine continued for a time but yielded to further treatment at regular or irregular intervals. The method, they say, should be tried for patients who have frequent and copious vomiting, and for those who have tenderness over the gall-bladder on palpation; for it seems beyond question that migraine sometimes has its origin in biliary stasis. And in such cases regular drainage of bile into the intestine is a rational procedure.

The Enlarged Prostate.

Treatment of enlarged prostate by X rays cannot take the place of surgical intervention and finds its proper rôle as an auxiliary. Nevertheless, as Guilbert points out in the *Concours Médical*, it is of considerable efficacy and sometimes makes it possible to defer operation for long periods or even permanently. It is, he says, harmless, and may usefully be employed where patients are old and feeble. No form of treatment is satisfactory if it leaves the patient unable to profit by other measures in case of failure, and Guilbert advises that where operation may have to be done later the dosage and the period of irradiation should be strictly limited. Of 60 cases that he treated with X rays, four were subsequently operated on. Before irradiation is begun, it is essential to make sure that the wall of the bladder is intact and to get rid of sepsis by lavage and vaccines, as X rays generally provoke a sharp bout of cystitis if the bladder is infected. When the organ is already irritable it is well to be cautious in starting the treatment and the sessions should be at longish intervals.

Congress of Public Health.

The next annual international congress of hygiene will coincide this year with the 50 years' celebration of the foundation of the Société de Médecine Publique and will be held at Paris from Oct. 25th to 28th. The subjects of discussion are the relation of social insurance to the public health, the factors causing a world recrudescence of small-pox and the means of controlling them, and the hygiene of training camps. The chief contributions announced will be those of Prof. Madsen, President of the Health Committee of the League of Nations; Mr. G. H. F. Nuttall, F.R.S., professor of parasitology in the University of Cambridge; and Prof. Ottolenghi, of Bologna University. There will be an exhibition of hygiene (strictly technical) at the Pasteur Institute. Further information may be had from Dr. Dujarric de la Rivière, at the Institute, 26, rue Dutot, Paris.

Buerger's Disease.

Is thrombo-angiitis obliterans a separate disease? According to Buerger it is special, and even exclusive, to the Jews, being found in young subjects, chiefly males. Although unrelated to syphilis, it originates, in his view, in an infection which sets up thrombosis and afterwards a secondary sclerosis in the vessels. The personal observations of Guillaume, recently reported to the Société Médicale des Hôpitaux, suggest that Buerger's disease is not a clinical entity at all but a juvenile form of obliterative arteritis. The supposed anatomical, ætiological, and clinical characteristics do not appear, he says, with absolute regularity.

During the recent visit of the American Legion to Paris the emergency medical service organised by the French and American Red Cross cared for some 200 cases of minor injuries, colds, fatigue, and exhaustion, and referred several graver cases to suitable hospitals.

The Lyons Court of Appeal has decided that surgeons are not responsible for faults committed by midwives working under their direction.

The death is announced of Dr. L. C. A. Prenaut, professor of histology in the University of Paris, and one of the best-known histologists in France. He was born at Lyons in 1861.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Law against Venereal Disease.

THE new legislation described some time ago in THE LANCET [1] has now come into force, and the authorities are engaged in putting its provisions into practice. As there is no precedent for the system it is difficult to predict how it will work and what will be the results. Since Oct. 1st the work of the police in registering and examining prostitutes has ceased and the task of prevention and cure is now entrusted to special municipal officers. Local authorities have to set up boards of which a specialist in venereal diseases will be a member; the duty of these boards will be to require certificates of the state of health of all persons—male or female—who are suspected of suffering from and spreading venereal disease, and they will have to order a compulsory examination of any such person who does not voluntarily produce the certificate demanded. They also have to provide for the attendance of the patients and if necessary for their isolation in hospital, and to receive information concerning infections and notifications from medical men if patients discontinue treatment before they are cured. In a circular letter to the local authorities the Minister of Public Health insists that much tact should be used to avoid annoyance of the public. For instance, letters to patients must be sent in an envelope without the address of the sender, so that other people cannot ascertain that the letter comes from the health authority. In Berlin the work was inaugurated at a meeting in the town hall, where speeches were delivered by the directors of the Government Health Office and of the Municipal Health Office, and by representatives of the medical profession and of the sick-clubs. The Municipal Health Office will arrange public lectures at 50 different places in Berlin where medical men will invite the public to take part in the campaign against venereal disease.

Overcrowding of the Profession.

The Association of Medical Practitioners (the Ärzte-Vereinsbund) and the affiliated medical union,

[1] THE LANCET, 1927, i., 565.

the Hartmann-Bund, held their annual meeting in Würzburg recently, when the first discussion was devoted to the present position of the younger members of the medical profession. By a Government order under the Emergency Act of 1923, medical men are not admitted to club practice until three years after they have qualified, and the result is that about 2000 of them have hardly any work. The regulation was made as a result of overcrowding in the profession, and in order to limit the number of entrants several speakers advocated that the period of medical study should be lengthened and that examinations should be made more severe. Against this it was argued that the extension of medical study would make it more expensive and thus create a danger of its becoming the monopoly of the well-to-do. Some delegates considered that a central medical register should be kept from which younger medical men should be selected and distributed over the country to places where there is need for medical aid. At present only about 1200 medical men are admitted to club practice annually, whilst about 2000 leave their assistantships in the hope of being able to establish a practice. The Association almost unanimously adopted a motion that the three years' waiting period should be abolished. The relation between the boards of social aid and the medical practitioners was then discussed and a motion adopted that the medical officers of these boards should abstain from interfering with private practice.

Compulsory Inoculation against Diphtheria.

At a meeting of the German Society for School Hygiene lately held in Saarbrücken Prof. Klotz, of Lubeck, advocated compulsory inoculation against diphtheria in the first year of life. Vaccination against small-pox, he suggested, should not be performed, as hitherto required by law, during the first year, but should be postponed until the child enters school. Every child going to school ought to produce a certificate that it had been inoculated against diphtheria and small-pox. If Prof. Klotz's proposal were to be adopted the present law should, of course, be completely altered, and certainly the proposed change would revive the old campaign against compulsory vaccination. The society was of opinion that infectious diseases would be reduced if the number of pupils in a single class-room was not allowed to exceed 30.

The Study of Rheumatism.

A society for study of rheumatism has been founded in Berlin to take part and to help the international combat against that disease organised by the International Society of Medical Hydrology. The former president of the Prussian Health Department is chairman of the committee, which includes medical men engaged in the study of climatology and balneology, and representatives of health resorts and of sick-clubs. Prof. August Bier, Prof. Wilhelm His, and Prof. Alfred Goldscheider, of Berlin, and Prof. Friedrich Müller, of Munich, have been elected honorary members.

The Health Committee of the League of Nations now visiting Germany includes 28 medical officers from 22 different countries. Their programme has included inspection of numerous hospitals and other institutions in Berlin, and they will go to Hamburg, Essen, Düsseldorf, Halle, Dresden, Chemnitz, Leipzig, Kissingen, Nürnberg, and Munich before returning to Geneva.

The German Society for Industrial Hygiene has formed a committee to investigate the relation which exists between the constitution of the industrial worker and his fitness for work. Special attention will be paid to internal secretion and heredity. The committee, whose chairman is Dr. Krohne, head of the Prussian Health Department, invites those who intend to do work in these fields to apply to the committee, which is prepared to give financial assistance under certain circumstances.

Public Health Services.

REPORTS OF SCHOOL MEDICAL OFFICERS

Name of district.	No. on roll.	Av. elem. school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.*
County of Cambridge ..	9819	8889	3227	6193	9·1
Northampton ..	—†	—†	3589	7025	17·1

* Excluding uncleanliness and dental defects.
—† Not given.

County of Cambridge.

Dr. F. Robinson, M.O.H. and S.M.O., states there ha been an increase of 627 in the number of routin inspections during the year. In this area, as in man others, nutrition has considerably improved sinc 1912, though the rise in the years during an immediately after the war has not been fully mai tained. The assistant medical officer, Dr. Jess Gellatly, has traced in a local area a close relatio between the nutrition of the children and speci economic conditions. Efforts are made to mainta a high general standard by the provision of scho meals for the small charge of 1s. a week; this pr vision is made increasingly necessary by regroupi of schools which causes children to travel long distanc from their homes. Specimen menus indicate excelle dietaries and accounts show that the schemes ar in spite of free meals to necessitous cases, nearly se supporting. Less complete but useful alternativ or adjuncts are the supply of cocoa and the heati or cooking of food brought by the children. F cases of real subnormality oil and malt is provide and Dr. Robinson says that the very satisfactory resu it gives are quite out of proportion to the small su of £80 per annum which is expended. It is, as he sa curious to note that even in so simple and famili a matter as the giving of cod-liver oil, opposition shown by some parents, who regard such assistan as an affront or permit the likes and dislikes of t children to prevail just as they do when den treatment is recommended. On the latter subj the school dentist, Mr. Evered, reports that about or third of those requiring attention refuse treatme He thinks that the chief obstacles are still the unreasc ing ignorance of the parents and their evasion responsibility by leaving the decision to the chi During the winter lectures have been given and fil shown to mothers at some maternity centres a women's institutes on the care of children's tee The dental work of the county is extensive, childr between 5 and 14 years of age being dealt with, a in the smaller schools the younger children also.

Figures for cleanliness show little recent alterati though there has been a substantial improvem since the early days of school medical inspecti The standard will probably rise with betterment housing. Of uncleanly bodies, Dr. Robinson poi out that the better the facilities for washing in the schools the greater is the importance wh the children attach to exhortations on cleanlin He gives examples of slow progress in improv school sanitation, which are very pertinent. Th are no special schools or orthopædic scheme for t county, but some use is made of facilities in the to of Cambridge and elsewhere.

Northampton C.B.

Dr. Stephen Rowland, M.O.H., S.M.O., and ch tuberculosis officer, only took over the post a

December after the death of his precedessor, Dr. J. D. McCrindle, and cannot give an exhaustive account of the work done under the former régime.

It has been found impossible for one medical officer to carry out all the inspections required by the Board of Education and arrangements are being made to provide help. The detailed record of school work by Dr. J. H. Mason mentions that routine inspections are still separated by much longer intervals than they should be. An increase of staff should have several good results; for instance, it will be possible for medical officers to coöperate in the work of school camps as has unfortunately been impossible this year. It is a regrettable fact that a certain number of children are kept out of school for long periods by neglectful parents who extract from harassed practitioners certificates of unfitness for school for many weeks at a time, and thus protect themselves from the attendance officers, while the children are allowed to run the streets or are even used as drudges at home. Dr. Mason thinks that the majority of these children could be promptly readmitted to school if they were examined by a tactful S.M.O. who explained matters to the parents and referred them back to their own doctor for his permission and agreement that the child should return to school. Another difficulty in Northampton is the lack of an open-air school, for sometimes the practitioner, while not quite certain that a child is fit for an ordinary elementary school, would be in hearty agreement with his colleague that attendance at an open-air school is desirable. Particularly important is the case of the "pre-tuberculous" child, who is kept out of school for long periods on medical certificates of anæmia and debility, thus missing much valuable education and the real chance of permanent restoration to health, which he could get at a properly constituted open-air school, where he would have a special curriculum, extra rest, and appropriate feeding. This matter, Dr. Rowland says, "has received special consideration and it has been decided as impracticable at the present time and until improved financial possibilities come into existence further suggestions will have to be withheld." Other authorities have seen that in such questions delay is really extravagance.

In one direction the borough has shown more foresight. Although salvage is nothing like so swift and obvious with the mentally defective, yet the record of the ex-pupils of the special mentally defective school shows that, excluding those who have died or left the town, about half are in more or less satisfactory employment. It is noted that in times of full employment a high percentage are wage-earners, but many are unable to stand the constant strain of regular work. The wages earned during the year have varied from 10*s.* to 30*s.* a week and where consideration is shown by employers a good report is usually given. There can be no doubt that without the special training the number of those who support themselves would have been much lower.

The dentist's report shows much good work done, but the fact that with permanent teeth the number of extractions was two-thirds the number of the fillings, and the large proportion of "casuals" among the treated, suggests that the staff is too small.

Soke of Peterborough C.C.

Dr. Christopher Rolleston reports all-round improvement during the year in the well-being of the children and the hygienic arrangements of the schools. The response of parents to the increased medical supervision is encouraging; 75 per cent. of the parents were present at medical inspections and the new scheme in connexion with the Manfield Orthopædic Hospital at Northampton has had immediate success, all the children recommended for treatment having accepted it. Advantage has also been taken of the extended facilities for ophthalmic treatment, and every child requiring glasses has obtained them. Of those recommended for surgical treatment of tonsils and adenoids, 53 per cent. have had the operation. Cleanliness and freedom from the "dirt" diseases are also on a high standard, whilst the percentage of ill-nourished children has fallen from 8·4 in 1920 to 4 in 1926. The new dental facilities are not yet being fully used, and Dr. Rolleston hopes that lectures on dental hygiene will be included in the proposed course of lectures by the Soke of Peterborough Insurance Committee.

Investigating the circumstances of the children requiring operative treatment for tonsils and adenoids, Dr. Rolleston found the percentages of breast- and bottle-fed children was much the same as in children without these abnormalities, but dental caries, deafness, and aural defects were much commoner among those with tonsillar defects, 14·6 per cent. of whom showed malnutrition, as against 2·6 per cent. of normal controls. Rheumatic manifestations and heart disease appear to be relatively rare in this neighbourhood as only one case of organic heart disease is reported. The school nurse receives a justifiably generous tribute from Dr. Rolleston, for in addition to 4766 routine examinations for cleanliness she paid home visits to children recommended for treatment and to all cases of infectious diseases, besides helping at medical and dental clinics, carrying on the nursing treatment of minor ailments and conducting children to hospital.

Ramsgate.

To an outsider visualising Ramsgate it comes as a surprise to find the multifarious health duties are performed by one medical officer, Dr. W. J. Bannister, M.O.H. and S.M.O. Besides his public health and school medical work he is bacteriologist and port sanitary officer. His school report suggests efficient work and includes a thorough sanitary survey of all the schools in the borough; although he does not lay stress on defective conditions, yet he makes their existence sufficiently evident to prepare us for the final remark that one of the schools has been condemned by the Board of Education and will have to be replaced. There is a natural tendency for a medical officer with a wide range of duties to have less time for and perhaps to attach less importance to individual special subjects. Thus whilst an aural surgeon might say that the majority of chronic affections of the nose and throat need operative treatment, Dr. Bannister insists on this in only 11 out of 119 cases, deeming the remainder adequately dealt with by dental treatment with oral and nasal hygiene. Although the percentage of children suffering from the ordinary defects found at medical inspections is fully up to the average for the country as a whole, the number of exceptional children found—i.e., the blind, deaf, and mentally defective—is very low. Associated with this finding, whether as cause or effect, must be taken the fact that "there are no special schools in or near the borough." Of physically defective children, and especially of the delicate children, a good many have been noted, so that it is obvious that "a definite need exists for a school in which certain children could be educated throughout the year under open-air conditions." Dr. Bannister states that this provision will have to be postponed on account of its cost, but suggests that in the new school a special class should be provided for open-air education.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 1ST, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 122 (last week 125; it may be noted in passing that the number of cases is stabilising itself); scarlet fever, 2028; diphtheria, 1094; enteric fever, 86; pneumonia, 612; puerperal fever, 40; puerperal pyrexia, 106; cerebro-spinal fever, 7; acute polio-myelitis, 26; acute polio-encephalitis, 3; encephalitis lethargica, 20; continued fever, 1; dysentery, 111 (last week 1); ophthalmia neonatorum, 131. No case of cholera, plague, or typhus fever was notified during the week. Of the 29 cases of combined poliomyelitis and polio-encephalitis 7 (last week 14) were notified

from Kingston-upon-Hull and 6 from the West Riding of Yorkshire. The incidence of encephalitis lethargica is still low, but does not approach last week's extraordinarily low figure (12). Of the cases of dysentery, of which 110 more cases were notified last week than the preceding, 1 was reported from the county of Essex (West Ham C.B.), 4 from the county of Lancaster (Liverpool 1, Salford 1, Clitheroe 2), 1 from the county of Denbigh, and 105 from the county of Stafford (18 of these from Stoke-on-Trent C.B., and 87 from the urban district of Kidsgrove).

We understand that the Kidsgrove and Stoke-on-Trent outbreak, at first reported as dysentery, was probably a milk-borne epidemic of food poisoning due to *Bacillus aertrycke* (Mutton). The means by which this organism gained access to the milk has not yet been ascertained, but bacteriological and other inquiries are proceeding. There were over 100 cases and two deaths, but fortunately the outbreak now appears to be at an end.

DRAINAGE OF A PELVIC ABSCESS PER RECTUM.

To the Editor of THE LANCET.

SIR,—I can support Mr. Hamilton Bailey's advocacy of rectal drainage in pelvic abscess, having practised it for years. I learned it from F. T. Paul, who laid down a very useful certain indication for its use. It is true it applies only to a late case, but if the condition is found—and I have known Paul examine a case rectally every day for a week until it was found—it is absolutely safe to open the abscess into the rectum. The condition is a hard board-like swelling above and in front of the rectum, with a soft spot in the middle. Only if this condition is present can one be absolutely certain of not opening coils of small intestine.

I am, Sir, yours faithfully,

Liverpool, Oct. 8th, 1927. FRANK JEANS.

MISLEADING QUALIFICATIONS.

To the Editor of THE LANCET.

SIR,—Your correspondent, "Ethics," raises the question of whether anyone is entitled legally or ethically to designate himself F.R.C.S. without specifying the Royal College of Surgeons to which he belongs.

It is no more unethical to use the short term than it is for anyone possessing the doctorate of a university to use the term M.D. without stating the name of the university where he obtained his degree. If it is unethical to use the abbreviation F.R.C.S., then the Fellows of the Royal College of Surgeons of England are by far the greatest sinners, as it is not usual for them to sign themselves F.R.C.S. Eng. on every occasion.

Your correspondent's grievance seems to be that someone on the staff of a cottage hospital outside London who has a surgical Fellowship "has gained much public esteem." If "Ethics" realises the severity of the examinations of any of the British colleges and the high surgical attainment necessary to obtain their Fellowship, then he should be willing to accede all the esteem such an attainment deserves. Perhaps he thinks only Fellows of the Royal College of Surgeons of England are deserving of esteem as is hinted in the last clause of his letter.

I am, Sir, yours faithfully,

Oct. 10th, 1927. F.R.C.S.

THE CUTI-DIAGNOSIS OF SCARLET FEVER

To the Editor of THE LANCET.

SIR,—In the Medical Annual, 1927, appear o successive pages two articles describing recent wor on scarlet fever and the Dick test. In the first these, signed by Dr. J. D. Rolleston, one read (p. 442) :—

"W. A. Brown, whose observations on the Dick test we carried out under the reviewer's observation, confirms t value of the Dick test as an index of susceptibility to scarl fever, and maintains that it is a valuable aid to diagnos a strongly positive skin reaction in the first 48 hours of scarlatiniform eruption being against the diagnosis scarlet fever."

Turning to the second article one finds the te described; the left arm is chosen for the purpos and the writer (Dr. J. Priestley) proceeds :—

"The reaction in the left arm may be (1) positiv (2) negative, (3) positive and pseudo, (4) negative a pseudo—the positive reaction coming on in 4 to 12 hou and lasting only 24 to 48 hours, and without subseque straining or desquamation. A definite flush (about half inch in diameter or larger) is to be regarded as a positi reaction. Of persons suffering from definite scarlet fev 80 per cent. give a positive result to the test in the ea part of the attack, the reason for the absence of reacti in the remaining 20 per cent. being at present unexplainabl

One feels that there is more to explain than mere 20 per cent., and I have written this letter confidence that the explanation will be forthcomi but for my part I came out by the same door as I went.

I enclose my card, and am, Sir,

Yours faithfully,

OBSCURISSIMUS.

*** On referring to Dr. Brown's original arti it will be seen that with toxin of 1/1000 streng all of seven cases of early scarlet fever gave a positi reaction. It was with the high dilution of 1/60 that the small ratio of positive results was obtain There is wide agreement that with a selected streng of toxin a positive reaction is given in 70 to 85 cent. of cases of early scarlet fever. Dr. Rollest admits this, but writes that, in his experience, t reaction is not *strongly* positive, and he agrees w Dr. Brown in regarding a strongly positive reaction against the diagnosis of scarlet fever.—ED. L.

INCOME-TAX ASSESSMENTS.

To the Editor of THE LANCET.

SIR,—It would be well to remind your readers the importance of giving immediate attention to notices of assessment which are now being iss with reference to 1927–28.

Twenty-one days is allowed in which to app the period counting from the date of the notice not from the date of receipt. Unless notice of ob tion is given to the inspector in writing within period, and the ground of the objection is stat it may be found at a later date that the collec can legally demand payment of income-tax wh might have been saved by taking the appropri action now.

Every notice of assessment should be carefu examined for possible errors in the amount asses or in the allowances and the calculation of t Reliefs which are likely to be missed are those gran to persons over the age of 65, margin relief on assurance premiums, married allowance where marriage took place after April 5th, 1927, and o somewhat obscure allowances.

I am, Sir, yours faithfully,

W. R. FAIRBROTHE

Income-tax Specialist

67–68, Cheapside, London, E.C., Oct. 10th, 1927.

THE LATE PROF. ADRIAN STOKES.

To the Editor of THE LANCET.

SIR,—It was in September, 1914, following the attle of the Marne, that I met Adrian Stokes at a lace called Fère-en-Tardennois, a small town some en miles south of the Aisne. Stokes was riding a otor-cycle with side-car when he asked me to tell im where he could get engine trouble seen to—this was able to do. Having been through all the rough-nd-tumble with the old B.E.F. from Mons to the arne I hoped, as a reward for my assistance, that tokes might produce from his car cigarettes, tobacco , equally acceptable, a cake of soap. But my int as to the possible contents of his car including, r me, then, such luxuries, resulted in the discovery what I believe must have been the first mobile boratory on service with the B.E.F., for the side-car ntained nothing but laboratory equipment. At ch a time and place, during the hot pursuit of a treating enemy, to find, amongst the pell-mell of ttle almost, a "unit" of this description made e inclined to agree with a Frenchman to whom I sclosed Stokes's objective that "*il est bien toqué type la.*"

In October, 1914, I met Major S. D. Rowland at . Omer, and eventually saw his motor wagon boratory parked in the grounds of the College of . Joseph in that town. Later still I joined, from up country," for duty with No. 7 General Hospital, E.F., as the Belgian typhoid hospital had been designated, but Stokes was no longer doing duty ere. I merely write this letter because I believe it as Stokes who initiated the motor laboratory rvice of the B.E.F. with his motor-cycle and side-r in September, 1914, whoever conceived the idea such a service or launched it later.

I am, Sir, yours faithfully,

Oct. 10th, 1927. J. H. P. G.

The Services.

ROYAL ARMY MEDICAL CORPS.

Maj. P. Dwyer to be Lt.-Col. to complete estabt.
Capt. H. H. R. Bayley to be temp. Capt., and temporarily nquishes the rank of Capt.

ARMY RESERVE OF OFFICERS.

t.-Col. E. F. Q. L'Estrange, having attained the age it of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

ol. F. H. Westmacott, K.H.S., having attained the age it, is ret. on completion of his tenure of appt. as A.D.M.S. d (E. Lan.) Div., and retains his rank with permission wear the prescribed uniform.

r. S. S. Sokhey, Dr. B. P. B. Naidu, and Maj. Covell have been appointed to the Medical Research artment. Maj. H. H. Khan, whose services have been ed temporarily at the disposal of the Government, tral Provinces, Jail Department, has been appointed ttached officer, Central Jail, Jubbulpore. Lt.-Col. G. W. ilton has been appointed a member of the Bengal islative Council.

Obituary.

HENRY BRUNTON ANGUS, M.S. DURH., F.R.C.S. ENG.

Mr. H. B. Angus, Emeritus Professor of Surgery in the University of Durham, who died on Oct. 4th, was the son of James Ackworth Angus, of Newcastle-upon-Tyne, who was himself devoted to surgery in his younger days. He was born in 1867 and educated at the Royal Grammar School in his native city and at the Medical School of the University of Durham, then situated in Orchard-street, Newcastle-upon-Tyne. Subsequently he took a course at St. Bartholomew's Hospital, and he often spoke of the great value of the time he spent in London. On graduation in 1890 he was appointed house surgeon to the late Mr. G. E. Williamson, and afterwards at the Southport Infirmary and Dispensary. Returning to Newcastle, he became one of the resident medical officers to the dispensary in Nelson-street, and it was while serving there that he may be said to have begun his surgical career. Examinations were anathema to him, but he was always a determined plodder, and in 1900 he took the M.S. degree in his own university and in 1902 became F.R.C.S.Eng. In 1896 he was appointed assistant surgeon to the Royal Infirmary in Newcastle, and after serving a fruitful ten years in this capacity with the late George Halliburton Hume, to whom he was a devoted lieutenant, he was appointed full surgeon in 1905, and only resigned in April of this year for reasons of health, being then appointed consulting surgeon. In 1909 he was made lecturer in surgery in the University of Durham, and in 1921 succeeded to the chair on the retirement of Prof. Rutherford Morison. Only in July of this year he was made Emeritus Professor, when he finally decided that he would have to relinquish his teaching duties. Throughout the war he served on the staff of the 1st Northern General Hospital with the rank of lieutenant-colonel, and subsequently he was on the staff of the Pensions Hospital.

PROF. H. B. ANGUS.

For the following account of Prof. Angus we are indebted to Prof. Grey Turner: "When I first came to know 'Harry' Angus—a term of endearment by which he was known throughout his professional life—he was senior resident at the Newcastle Dispensary, and in that capacity he did a good deal of surgery in the homes of the poor, following a tradition which had been set by his predecessor in office. Soon afterwards he was appointed assistant surgeon to the infirmary, and I well remember attending his out-patient department. He was very keen and interested in problems of diagnosis, and I can never forget the impression which he made by the way in which he discussed the problems presented with members of his class, treating us like colleagues rather than students. . . .

"When he got charge of wards he devoted very considerable attention to injuries and especially fractures and to industrial accidents, for his experience of compensation cases had taught him the great economic importance of the careful treatment of this class of case. He had quite a bent for plastic and reconstructive surgery, and this found an ample field in his war work and after. Angus was always keen

on the records, and in his earlier days at the hospital he very often wrote the notes himself, as many of the old case-books bear witness. His ward teaching was simple and direct, and he encouraged men to concentrate on those subjects that fitted them best for their life's work. For student purposes he would never allow himself to be tempted to deal with rare cases or abstruse problems, as he considered that their hospital time was only too short for learning the essentials. He always kept up his interest in anatomy and he hammered in the importance of a good regional knowledge of this fundamental subject. As an examiner he was patient and considerate and scrupulously fair, but though very anxious to give every student a full opportunity of demonstrating his knowledge, he realised the responsibilities of his office and did not allow himself to be swayed by sentimental or other considerations, and I have often heard him say that it was an unkindness to an improperly prepared candidate to allow him to get through. When the X ray department was first started in the old infirmary Angus had charge, and there must be many who remember that little dark room at the end of the Ravensworth Ward, where he groped about in more senses than one, endeavouring to master the technique of radiography and to discover the secrets of its successful application. He never published much, but his papers were all thoroughly practical and without unnecessary padding.

"In the medical school and the infirmary he did a liberal share of committee work. His opinion was always welcomed, for it was sure to be entirely disinterested and quite often he saw things from an angle which had escaped the rest of us. He was one of those men who could be easily led but never driven, and he could be particularly difficult when he imagined that some wrong was being done or that the dignity of the profession was being slighted. In his earlier days he was an athlete, and all through life he recognised the great value of healthy sport and always encouraged the sporting functions in connexion with the College. In later years he became especially devoted to fishing, but he was also a good shot.

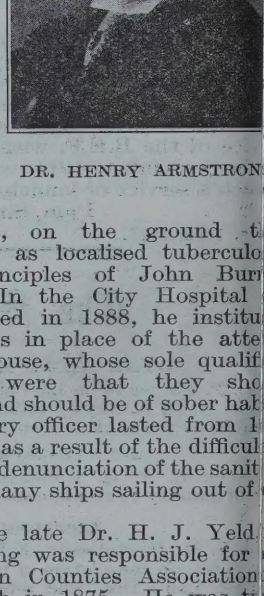
"I cannot imagine Angus ever having an enemy. He was always generous and open-hearted and never allowed any small service to go unrequited. He was open-minded in every way, and though conservative in his methods he was always willing to be convinced of some improvement; but he had to be satisfied that the improvement was to be for the advantage of the patient before he would make any change in his technique. It was characteristic of him that he carried out his allotted task to the very best of his ability, and whatever he undertook he did as well as he possibly could. In everything he was absolutely and transparently honest, and as often as not the stories which he related were against himself. He had the habit of sometimes thinking aloud, and as he never took pains to dissimulate, the consequences were sometimes a little embarrassing. Fortunately he was of a philosophic turn of mind, and he accepted stoically whatever fate had in store, and though he could grouse like the rest of us on occasion, he never whined. He was an excellent influence in the medical school, an ideal hospital officer, and the very model of the perfect English gentleman. Could more be said to show how keenly we in Newcastle feel his loss?"

Mr. Angus married Miss Maude M. Arnison, who survives him with two daughters.

HENRY EDWARD ARMSTRONG, M.R.C.S. ENG., D.HY. DURH.

Dr. H. E. Armstrong, who died on Oct. 5th in his eighty-fifth year, was the first medical officer of health of Newcastle-upon-Tyne. Born at Chipchase Mill, North Tyne, of old yeoman stock, he went to school at Brampton, served his apprenticeship at the Newcastle Dispensary, studied at the Newcastle College of Medicine (Neville Hall), and qualifi in 1864. He was then given resident char of the old Newcastle Dispensary in City-roa and the old Fever House (founded in 1807), a in 1873, when the City Council resolved to appoi their first whole-time medical officer of healt Armstrong was the obvious man for the post. held office until the end of 1912, when he retired pension.

The story of Armstrong's life is closely associat with the rise of sanitation in England, for he was t intimate friend of such men as Buchanan, Thorn Thorne, Power, and Murphy. When he took off Newcastle was an ancient city clinging desperately its stifling courts and crumbling tenements. It largely due to his persistence that practically all the old rookeries are now swept away, so that, although it has its housing difficulties, it has now singularly few slums. A glance at his early reports will show him advocating many of the newest ideas of to-day. He was one of the earliest workers against bovine tuberculosis, and as far back as 1892 Newcastle obtained powers, limited it is true, to deal with tuberculous milk. It was his practice to condemn and seize the whole carcass of a food animal showing any evidence of tuberculosis, on the ground t there was no such thing as localised tuberculo He anticipated the principles of John Bur Milk and Dairies Bill. In the City Hospital Infectious Diseases, opened in 1888, he institu a proper service of nurses in place of the atte ants in the old Fever House, whose sole qualif tions for appointment were that they sho have had "the typhus," and should be of sober hab His charge as port sanitary officer lasted from 1 till 1896, when he resigned as a result of the difficul created for him by his bold denunciation of the sanit conditions prevailing on many ships sailing out of river Tyne.



DR. HENRY ARMSTRON

In association with the late Dr. H. J. Yeld Sunderland, Dr. Armstrong was responsible for founding of the Northern Counties Association Medical Officers of Health in 1875. He was tw chosen as president of the parent society and elected an Honorary Fellow in 1920. But his w was confined within no rigid limits. He was v closely associated with the growing University Col of Medicine, and from 1878 to 1887 acted as honorary secretary and subsequently as a gover He was himself a lecturer in the College for ne 40 years, at first on botany and later on hygiene in widest sense. The degree in hygiene in the Univer of Durham, which he did much to found, he was first to obtain.

Dr. Armstrong had strong literary tastes, and a scholarly and widely-read man; Dr. H. Kerr, has contributed these biographical notes, writes him as a purist in style; a piece of slovenly composi in the report of a subordinate would cause him a irritation. He was methodical in his work, insisted upon punctiliousness in all office affairs. dabbled in music and art, was a keen photograp an enthusiastic angler, and well-travelled. At age of 65 he took up roller-skating, and spent muc his spare time for some years subsequently in vigorous pursuit. He had the warm affection his staff, and his was always a happy dep ment, no matter what troubles assailed it f without.

ALFRED JAMES MEYRICK PAGET, M.D., C.M. EDIN.

Alfred James Meyrick Paget, who died on Sept. 15th
Christchurch, Hants, was the third son of the
e Sir George Paget, Regius Professor of Physic
Cambridge, by Clara, daughter of the Rev.
omas Fardell. He was educated at the Uni-
rsity of Edinburgh where he graduated in
dicine and surgery in 1895, proceeding to the M.D.
o years later. He elected to practise abroad in
overnment appointments, and served under the
reign and Colonial Offices in Kenya from 1899
til 1904, after which date until 1916 he was senior
dical officer in Somaliland. This included the
riod during which the Mad Mullah caused so much
uble with the British authorities, and Paget's
sponsibilities were grave, aggravated as they were
the heavy incidence of tuberculosis upon the
ritory, as well as severe epidemics of small-pox.
came into the vast zone of the war, and for his
vices to the troops during the military operations
received the Somaliland Medal. At his own expense
fitted up and, where needed, rebuilt the ruins of
ort near Berbera in order that it might be used as
isolation hospital for tuberculosis. This building,
ich was popularly known as "Paget's Folly,"
s beyond the British fortifications, and useful work
s carried out at it, until at last it was looted by the
ives. Much of Paget's strenuous labours were
ried on in the face of personal ill-health. He
s at one time and another the victim of malaria
l scurvy, and heart trouble manifested itself.
was invalided in 1900 but returned to hard work
til in 1916, when he was 47 years of age, he could no
ger undertake the physical toil, especially the long
nel rides necessitated by his colonial appointment.
in 1917, as an officer in the Territorial Army, he
rked in the mental wards of the Lord Derby
spital and also at Ripon; and later, until two years
, he served under the Ministry of Pensions, where
keenness for work caused him to be retained beyond
usual period. On the termination of his engage-
nt with the Ministry of Pensions, he took a super-
nerary medical office at St. Mary Abbott's Hospital,
nsington, but in May of this year it became obvious
t he was suffering from his old tuberculous mischief.
vular heart trouble supervened and he retired to
ristchurch where he died.

He leaves three sons, one of whom qualified as a
dical man in 1924.

WILLIAM SMITH PORTER, M.D. DURH.

BY the sudden death of Dr. W. S. Porter, Sheffield
t the neighbouring district loses one who had been
amiliar figure both in medical and social circles
ring the last 40 years. Born in 1855 at Sheffield,
ere his father, John Taylor Porter, F.R.C.S., was
ractice before him, he was closely associated with
dical affairs throughout his life. He was educated
Repton School, Leeds Medical School, and King's
llege, London, and after qualifying as M.R.C.S. Eng.
878, proceeded to the M.D. Degree of the University
Durham in 1882, receiving the gold medal. His
st resident post was at the General (now the Royal)
rmary, and on starting private work as a consulting
ysician he joined the honorary staff first of the
spital and later of the infirmary. During all those
ars he was also actively engaged in teaching at the
school of medicine and later at the University,
ng for many years lecturer in medicine. As a
nsultant he was well known and respected not only
Sheffield, but for a wide area around; he belonged
the old school of courtly and cultured physicians.
his younger days he did some useful work in
nexion with lead poisoning from the water-supply,
was one of those who went to Berlin when
erculin was first introduced by Koch. As the years
t on, however, his real interests centred less on
dicine and more on the studies which he had always
ined to—that is, local history and local archæology.
His knowledge on these subjects was wide and deep, and anyone seeking information about old Sheffield went first to Dr. Porter to obtain it. From time to time he published the results of his work, and his writings were always pleasing and of literary merit.

"Up to quite recently," writes a colleague, "he was a great walker. The neighbouring hills and moors of Derbyshire were very familiar to him and he loved them very dearly. Many a younger man envied his long stride and his untiring energy in a long ramble. But to all who knew him Porter will be remembered first not as a physician nor even as an archæologist, but as a gentle, courteous, kindly companion, who never said an unkind word or thought an unkind thought of any man. His genuine enjoyment always added to the happiness of others, for he had the gift of never growing old."

Dr. Porter was at one time president of the Sheffield Medico-Chirurgical Society, and last year was president of the Sheffield Literary and Philosophical Society. He married in 1893 a daughter of the late Mr. Charles Lockwood. She died in 1922.

Medical News.

UNIVERSITY OF LONDON: *University College.*—A public lecture entitled the Static Reflexes of Magnus: How Animals Get Right-Way-Up and Keep So (with cinematograph illustrations), will be delivered by Prof. Arthur J. Hall, on Tuesday, Oct. 18th, at 5 P.M., in the Physiology Theatre (entrance in Gower-street). Dr. F. M. R. Walshe will take the chair and the lecture will be open to the public without fee or ticket.

HUNTERIAN SOCIETY.—The first dinner meeting of this session will be held at Simpson's Restaurant, 2 and 3, Bird-in-Hand Court, 77, Poultry, Cheapside, London, at 7.30 P.M., on Monday, Oct. 17th. At 8.30 P.M. Mr. A. E. Mortimer Woolf will give a Presidential Address on Some Personalities of the Hunterian Epoch.

EUGENICS SOCIETY.—On Wednesday, Oct. 19th, at 5.30 P.M., Dr. R. A. Fisher will speak on Multiple Births in Man; and on Wednesday, Nov. 16th, at 8.30 P.M., Prof. F. A. E. Crew will speak on Natural Immunity and Disease Resistance. Both meetings will be held at the rooms of the Royal Society, Burlington House, and all interested are invited to attend.

SOCIETY OF SUPERINTENDENTS OF TUBERCULOSIS INSTITUTIONS.—The next meeting of this Society will be held at 122, Harley-street, on Friday, Oct. 21st, at 3 P.M. Dr. J. Gravesen (Copenhagen) will speak on the Surgical Treatment of Tuberculosis of the Pleura, and Dr. Kennon Dunham (Cincinnati, U.S.A.) will read a paper entitled Various Types of Tuberculous Lesions as Seen Upon an X Ray Plate in the Child and the Adult, with lantern illustrations.

MEDICAL TOUR IN FRANCE.—Under the auspices of the Société Médicale du Littoral Méditerranéen a tour has been arranged to take place from Dec. 30th to Jan. 7th next. The places visited will include Hyères, St. Raphael-Valescure, Cannes, Grasse, Nice, Beaulieu, Monaco, Monte Carlo, Mentone, and particulars may be had from the Federation of the Health Resorts of France, 19A, Tavistock-square, London, W.C. 1.

THE Annual Medical Service will be held at Liverpool Cathedral on Oct. 16th at 3 P.M.; the preacher will be the Bishop of Chester. Applications for tickets for reserved area should be addressed to Dr. John Owen, 13, Rodney-street. It is requested that when possible academic dress be worn. A collection will be taken on behalf of the Royal Medical Benevolent Fund.

PEOPLE'S LEAGUE OF HEALTH.—A series of ten Sims Woodhead lectures is being given by the League in the lecture-room of the Medical Society of London, 11, Chandos-street, London, W., on Thursdays, at 6 P.M. The speakers are Prof. H. E. Roaf, Mr. E. B. Turner, Dr. J. Sim Wallace, Dr. Harold Gardiner-Hill, Prof. B. Collingwood, Prof. M. S. Pembrey, Prof. H. R. Kenwood, Dr. Thomas Beaton, and Dr. H. Crichton-Miller. The next will be given by Mr. E. B. Turner, on the Anatomy and Physiology of the Circulatory and Respiratory Organs, on Oct. 20th. Tickets for single lectures (1*s.* 6*d*) or the course (10*s.*) may be had from Miss Olga Nethersole, R.R.C., at 12, Stratford-place, London, W. 1. At its conclusion there will be an optional examination, with a travelling prize award.

Miss Ida C. Mann, M.B. Lond., F.R.C.S. Eng., has been appointed assistant surgeon to the Royal London Ophthalmic ("Moorfields") Hospital. She is the first woman to be appointed to the honorary staff of this institution.

ROYAL NORTHERN HOSPITAL.—Post-graduate courses will be held at this hospital from Oct. 25th onwards. They include a series of lectures on Tuesdays at 3.15 P.M., followed by tea, and an intensive course from Nov. 21st to 25th, when there will be numerous lectures and demonstrations in the wards. Further particulars may be had from the Dean, Dr. E. G. B. Calvert, at the hospital.

HELPING THE MANCHESTER HOSPITALS.—The Central Council of Voluntary Hospitals' Committees connected with the Manchester and Salford Medical Charities Fund is forming a Good Samaritan League with a minimum subscription of 5*s.* a year. The object is to make up the deficit of about £40,000 which every year weighs upon the hospitals of Manchester and Salford.

RADIOLOGICAL SOCIETIES.—It is expected that the amalgamation of the Rontgen Society with the British Institute of Radiology will be completed this month, and an exhibition and meeting are to be held on Nov. 17th and 18th at the Central Hall, Westminster, to mark the inauguration of the new body, to which the Society of Radiographers will continue to be affiliated. The proceedings will end with a dinner at the Great Central Hotel, Marylebone, on Nov. 18th at 7.30 P.M.

UNIVERSITY OF ST. ANDREWS.—The Principal, Sir James Irvine, at the autumn graduation ceremonial held on Oct. 7th, announced that the anonymous benefactor who had given £100,000 to the University was Dr. Edward Stephen Harkness, of New York. The gift would place St. Andrews in a unique position among the Scottish universities. More than one-fourth of the total sum was to be allocated towards the cost of building the new residence hall for men, with a view to restoring the old collegiate living, and there would also be scholarships carrying an obligation to reside within the University.

SOCIETY OF APOTHECARIES OF LONDON.—The Master's Day Dinner of this Society was held in its redecorated hall on Tuesday, Oct. 11th, Dr. R. Whiteside Statham, the Master, presiding, supported by Lieut.-Colonel C. T. Samman, R.A.M.C., and Dr. H. J. Ilott, respectively Senior and Junior Wardens. The Senior Warden, in proposing "The Health of the Master," dwelt on the family claim to the position which he occupied, as the nephew of a previous Master, and eulogised his assiduous attention to the business of the Court, in spite of the fact that he lived in Somersetshire, 134 miles from his work. The Master, in a studiously brief reply, pointed out the friendly associations which the Society had generally enjoyed with their senior corporation, the Royal College of Physicians of London, and their junior corporation, the Royal College of Surgeons of England. He strengthened his hereditary claim to the Mastership by mentioning that one of his ancestors had been Master before the Great Fire of London, which destroyed the neighbouring premises of the Physicians and also burnt down their own hall, which had been rebuilt, as the guests now saw it, immediately afterwards. He then proposed "The Health of the Royal Colleges," associating with the reply the names of Dr. Sidney Phillips, the Treasurer of the Royal College of Physicians, and Mr. F. J. Steward, Vice-President of the Royal College of Surgeons. Dr. Phillips, in detailing his personal relations with the Society, caused merriment by dwelling on the excellence of the tea which was always provided for the examiners; and Mr. Steward, also bearing testimony to the harmony which existed between his College and the Society, mentioned the quality of the tea-table hospitality. The toast of "The Guests," proposed by the Junior Warden, was responded to by Sir James Berry and Sir Henry Curtis Bennett. The President of the Royal Society of Medicine described how in his Serbian experiences he had been forced to wander from the paths of pure surgery into those of the physician and apothecary, travelling across mountains on horseback with a wallet of drugs of emetic, styptic, or evacuant nature. Sir Henry Curtis Bennett started amusingly by saying that there had been a good deal of talk about the tea of the Society, but that on this particular occasion he had chiefly come across their port; but he closed with an eloquent analogy between the position of the doctor, face to face with the naked body and soul of the sufferer, and the criminal lawyer, face to face with the fundamental morals of a tortured client. The proceedings at the dinner were enlivened with some really effective singing by Miss Vera Devna, and violin solos by Miss Winifred Stocken.

DURING the illness of Dr. R. J. M. Horne, fr injuries sustained in carrying out his duties, the Po Council have appointed his wife, Dr. Laura Katharine Hor to act for him as deputy medical officer of health.

ROYAL INSTITUTION.—On Tuesdays, Nov. 1st, 8 and 15th, Sir John Herbert Parsons will deliver a series three Tyndall lectures on Light and Sight.

A HOSPITAL SWEEPSTAKE.—In the hope of raisi at least £5000 the Metropolitan Hospital, Kingsland-road, had organised a sweepstake, with 6*d.* tickets, and £ worth of prizes, upon the race for the Cesarewitch. A several thousand tickets had been sold the scheme abandoned upon threat of a police prosecution. The hospi has held other sweepstakes on similar lines without objecti

HOSPITAL SAVINGS ASSOCIATION.—This associati reports that during the financial year ended July 31st interim payments amounting to £102,764 were made London hospitals in respect of services rendered to con butors and their dependents. The association has 350,(wage-earning supporters in London alone, and althou based on a regular weekly contribution of 3*d.* only, its inco has risen from £2000 in 1923 to £200,000 in 1927.

DONATIONS AND BEQUESTS.—Under the will of t late Sir Mark Oldroyd, J.P., of Batley and Whitby, testator left £1000 to the New Building Fund of the Dewsb and District General Infirmary (unless he had given such s in his lifetime), "being the sum I intend to contribute I live to lay the foundation-stone of such new build according to my promise given."

GENERAL LYING-IN HOSPITAL.—For the first ti since it was established in 1767 this institution, in York-ro Lambeth, is appealing for help. By the terms of the le under which it holds two adjacent houses, these structu which are almost derelict, have now to be rebuilt at a c of £40,000, three-quarters of which has yet to be rais The rebuilding will provide better accommodation for c patients, nursing staff, and pupils—the hospital has training school for midwives and monthly nurses, and ho refresher courses for those already in practice.

CHARING CROSS HOSPITAL DINNER.—The ann dinner of past and present students was held at the H Victoria on Oct. 5th, Dr. Cuthbert Lockyer in the ch As junior member of the staff, Dr. F. H. Young propo the health of the Hospital and Medical School, compar himself (amid applause) to King Henry VIII. in his atta ment to a second, younger, and more sprightly br Dr. W. J. Fenton, responding, referred to the retiremen Dr. Cecil Bosanquet, whose services would fortuna remain available for teaching; and to the election of Young as assistant physician and sub-dean. Dr. Pear and Dr. Hamilton had transferred their services to ot hospitals, Mr. J. B. Banister had succeeded Dr. Cuthl Lockyer as obstetric physician, and Mr. Everard Willi had been appointed to fill the vacancy thus left. The y said Dr. Fenton, had been very successful, 57 new stud (including dental students) having entered. The succe won were attributable to the careful individual atten of the teachers, to the fact that it was unnecessary to st many deep around the cases, and to the relative ease obtaining appointments. The site of the Royal Westmin Ophthalmic Hospital had been acquired, and £65,000 of the £75,000 required had been subscribed. With addition of this valuable site it would be possible to 60 beds to the hospital. A year ago the Patholog Institute had begun to take work from outside practitio so as to assist them in the proper treatment of pati who could not afford pathological investigations in ordinary way. So far as he knew the cases had all t of this kind, and neither in practice nor in intention there any competition with other pathologists. The sch was working well and was much appreciated. In conclus Dr. Fenton referred to the amalgamation of the Cha Cross and Royal Dental Hospitals and the conveni of this amalgamation to the students. Dr. J. M. H. Macl proposing the health of the chairman, referred to popularity, his success as a teacher, his contribution gynæcology, his unfailing courtesy, and the reputation w he had given to Charing Cross Hospital by his work. Lockyer, in reply, spoke of many contemporaries who brought distinction to the School, and notably of Frederick Mott whose loss, he said, was "not ours only shared by the whole world." This was the fortieth di that Dr. Lockyer had attended, and he expressed gratitude to those with whom he had worked during long a period. During the evening entertainment provided at intervals by Mr. Nelson Jackson, Dr. Ta Harris, and Dr. L. P. Phillips.

GUILD OF ST. LUKE.—The annual festival service of the Guild will be held in Westminster Abbey on Sunday, Oct. 23rd, at 6.30 P.M. The preacher will be the Bishop of Southwark.

GRADUATES OF THE UNIVERSITY OF EDINBURGH.—The West Riding Association of Edinburgh Graduates will hold its annual general meeting at the Great Northern Station Hotel, Leeds, on Friday, Nov. 4th, at 6.30 P.M. The meeting will be followed by the annual dinner, at which Prof. Edwin Bramwell will be the Association's guest. Further particulars may be had from the hon. secretary, 33, Manor-row, Bradford.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION. This Association has now issued its programme of post-graduate teaching in Glasgow during the winter months, including a series of weekly demonstrations. The syllabus may be had from the Secretary of the Association at the University, Glasgow.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—The new out-patients' buildings, including modern massage, electrical, and light departments, are almost completed, while the new building at the branch hospital at Stanmore will be ready for occupation next month. The extension scheme inaugurated by Prince Henry's special committee has been undertaken at a cost of £125,000, of which £80,000 has been collected.

SEAMEN'S HOSPITAL AT MARSEILLES.—The Queen Alexandra Memorial Hospital at Marseilles which has been under construction for some time past is now completed, fully equipped, and ready to receive patients. It is staffed by British nurses and there is a British house surgeon who will act under the direction of local English-speaking doctors. The charges to seamen will be based upon those ruling in the Marseilles municipal hospitals.

MEDICAL GOLFING SOCIETY.—The autumn meeting of this Society was held at Rye on Oct. 8th and 9th. The course was in beautiful order, and every arrangement was made for the comfort of the competitors. The results of the competitions were as follows: W. H. Lamplough won the singles v. bogey with 1 up, H. Chapple was second with 1 down, and G. Dawson and G. Hebert tied for third place with 2 down. L. Bromley and Surg.-Commander Rusack won the foursomes v. bogey with 2 down. The following tied for second place with 3 down: J. Everidge and M. S. Mayou, and J. C. Lee and D. Ligat. The Canny Ryall Cup was won by J. D. Gray with the score of 95−18 (77). T. A. Torrance (75+3). J. W. Harrison (90−12), and M. S. Mayou (90−12) tied at 78 for second place. T. A. Torrance won on the replay.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A series of lectures, entitled Practical Hints on Medicine, Surgery, and the Allied Specialties, will be given during the winter session at the house of the Medical Society, 11, Chandos-street, Cavendish-square, W., on Mondays, at 5 o'clock. The first will be given by Sir Humphry Rolleston on Monday, Oct. 17th, on the Diagnosis and Treatment of Some Endocrine Disorders. On Wednesday, Oct. 19th, at 4 P.M., Mr. Davenport will demonstrate at the Central London Ophthalmic Hospital; on Thursday, Oct. 20th, at 3 P.M., Mr. Attwater, Mr. Ainsworth-Davis, Mr. Coyte, and Mr. Loughnane will demonstrate at All Saints' Hospital; and on Friday, Oct. 21st, at 3 P.M., Dr. Bernard Myers will lecture at the Royal Waterloo Hospital on the Significance of the Enlargement of the Spleen in Children. These lectures and demonstrations will be open to members of the medical profession without fee. From Oct. 17th to 29th there will be an all-day course in Diseases of Children at the Paddington Green Hospital and the Victoria Hospital for Children. A two weeks' course in Gynæcology will start at the Chelsea Hospital for Women on the same date. From Oct. 24th to Nov. 5th, at 3 P.M., a series of demonstrations will be given at the Royal Eye Hospital, Southwark. A two months' comprehensive course is in progress at the National Hospital, Queen-square; any part may be taken separately. There will be practitioners' courses at the Hampstead General Hospital from Oct. 31st to Nov. 12th, and at the London Temperance Hospital from Nov. 21st to Dec. 3rd. The subjects of other courses during the month will be Medicine, Surgery, and Gynæcology, Royal Waterloo Hospital, Nov. 14th to Dec. 3rd; Diseases of the Chest, Brompton Hospital, Nov. 7th to 12th; Neurology, West End Hospital for Nervous Diseases, Nov. 21st to Dec. 17th; Urology, St. Peter's Hospital, Nov. 14th to 26th; Proctology, St. Mark's Hospital, Nov. 28th to Dec. 3rd; and Venereal Diseases, London Lock Hospital, Oct. 31st to Nov. 26th. Courses of all syllabuses are obtainable from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Oct. 18th.—5.30 P.M., GENERAL MEETING OF FELLOWS. Ballot for election to the Fellowship. 8.30 P.M., PATHOLOGY. Communications: J. McIntosh: The Histology of Some Virus Infections of the Central Nervous System. R. J. Ludford: The Repair of Superficial Skin Lesions in the Mouse. W. Cramer: Stomach Lesions in Rats Kept on a Diet Deficient in Vitamin A.

THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.) Cases: Dr. F. Parkes Weber: (1) Chronic Pemphigus or Dermatitis Herpetiformis in a Child. Dr. J. A. Drake: (2) Multiple Basal-Celled Epitheliomata. Dr. H. W. Barber: (3) and (4) Two Cases of Folliculitis Ulerythematosa Reticulata (MacKee). (5) Lichen Planus, Previously Shown as Lichen Nitidus. Other cases will be shown.

FRIDAY.—8 P.M., OBSTETRICS. Specimen: Mr. A. L. Walker: Rupture of the Uterus Following Cæsarean Section. Short Communication: Mr. A. C. Palmer: The Age Incidence of Carcinoma Corporis Uteri. Paper: Sir Ewan Maclean: A Lantern Lecture on a Visit to Certain Medical Schools in America. 8.30 P.M., ELECTRO-THERAPEUTICS. Presidential Address: Sir Henry Gauvain: Electro-Therapeutics and the Future of Medicine. Short Papers: Prof. Iselin (Bâle): Cancer of the Breast. Dr. Gravesen (Denmark): The Qualitative Radiological Diagnosis of Pulmonary Tuberculosis. A short paper will also be read by Dr. Dunham (Cincinnati).

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

THURSDAY, Oct. 20th.—8.15 P.M., preceded by a demonstration at 7.45, the President, Prof. J. W. W. Stephens, F.R.S., of Liverpool, will deliver the Inaugural Address on the Functions of the Spleen (illustrated by lantern slides).

LONDON CLINICAL SOCIETY, at the London Temperance Hospital.

THURSDAY, Oct. 20th.—9 P.M., Dyspepsia. Openers: Dr. John Ryle and Mr. Herbert Paterson. All medical practitioners are invited.

EUGENICS SOCIETY.

WEDNESDAY, Oct. 19th.—5.30 P.M. (in the rooms of the Royal Society, Burlington House, Piccadilly), R. A. Fisher: Multiple Births in Man.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Oct. 17th, to SATURDAY, Oct. 22nd.—FELLOWSHIP OF MEDICINE. Special lecture at the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on Monday, 5 P.M., by Sir Humphry Rolleston: Diagnosis and Treatment of Some Endocrine Disorders.—CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd-street, W.C. Wed., clinical demonstration by Mr. Davenport at 4 P.M.—ALL SAINT'S HOSPITAL, Vauxhall Bridge-road, S.W. Thurs., 3 P.M., demonstrations by Mr. Attwater, Mr. Ainsworth-Davis, Mr. Coyte, and Mr. Loughnane.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Fri., 3 P.M., lecture by Dr. Bernard Myers: The Significance of the Enlargement of the Spleen in Children. All of the above lectures and demonstrations are open to members of the medical profession without fee.—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C. Clinical course, all day.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Special course in Gynæcology. Mornings and/or afternoons.—LONDON SCHOOL OF TROPICAL MEDICINE, Endsleigh-gardens, W.C. Tues. and Thurs., clinical demonstration at 2 P.M. by Dr. Low and Dr. Manson-Bahr.—ROYAL FREE HOSPITAL, Gray's Inn-road. Wed., 5.15 P.M., lecture-demonstration by Dr. Heald.—PADDINGTON GREEN CHILDREN'S HOSPITAL, Paddington Green, W., VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea. Combined course in Diseases of Children, all day.—NATIONAL HOSPITAL, Queen-square, W.C. Special two months' course in Neurology. Further information from the Secretary, Mayfair 2236.

WEST LONDON HOSPITAL, POST-GRADUATE COLLEGE, Hammersmith, W.

MONDAY, Oct. 17th.—11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Simmonds: Surgical Out-patients. Dr. Ironside: Medical Out-patients.

TUESDAY.—10 A.M., Medical Registrar: Ward Demonstration. 2 P.M., Mr. Sinclair: Surgical Out-patients. 4.30 P.M, Dr. Shaw: Emphysema.

WEDNESDAY.—10 A.M., Dr. Owen: Medical Diseases of Children. 10 A.M., Dr. Burnford: Medical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Dr. Ironside: Medical Out-patients. 3 P.M., Sir H. Simson: Gynæcological Ward.

FRIDAY.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Mr. Addison: Operations; Mr. Vlasto: Aural Vertigo (lecture).

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy and Ward List. 10 A.M., Dr. Owen: Medical Diseases of Children.

Operations, Medical, Surgical, and Special Out-patients, daily 10 A.M. to 5 P.M.: Saturdays, 10 A.M. to 1 P.M.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Oct. 17th.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics, 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Oct. 18th.—5 P.M., Dr. H. W. Barber: Bacteriology and Mycology.

THURSDAY.—5 P.M., Pathology Demonstration.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, Oct. 20th.—4 P.M., Mr. Barrington-Ward: Hernia.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

WEDNESDAY, Oct. 19th.—4 P.M., Prof. Lyle Cummins: Tuberculosis as a Social Disease.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, Oct. 18th.—4.15 P.M., Dr. T. H. Oliver: Some Recent Views on Nephritis.

FRIDAY.—4.15 P.M., Dr. J. Gray Clegg: The Field of Vision.

Appointments.

CLAXTON, VERA E., M.B., B.S. Lond., has been appointed House Surgeon to the New Sussex Hospital for Women and Children, Brighton.

DEARNLEY, GERTRUDE, M.D., B.S. Lond., Consulting Gynæcological Surgeon to the Wembley Hospital.

PINKERTON, NORAH D., B.Sc. Wales, M.B. Lond., M.R.C.S. Eng., Assistant Medical Officer of Health for Bath.

Certifying Surgeons under the Factory and Workshop Acts: ROBERTS, J. F. M.D. Liverp. (Liverpool (Garston) District of the County of Lancaster); HAWES, W. A., M.B., B.S. Lond., D.P.H. (Stamford District of the County of Lincoln).

Vacancies.

HALLOWES.—On Oct. 3rd, at Elmsdale, Buckland Maidstone, Adolphus Henry Blackwood Hallowes, M.R. L.R.C.P., aged 83.

O'CONOR.—On Oct. 8th, at Buenos Aires, after a short ill John O'Conor, K.B.E., M.D., aged 63.

PORTER.—On Oct. 5th, suddenly, at Sale-hill, Sheffield, Wi Smith Porter, M.D., aged 71.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notic Births, Marriages, and Death.

A SHORT account of the work done for the pu health in Westminster has been issued by the Public H Committee and distributed by Dr. Andrew Shinnie, medical officer, in connexion with Health Week.

Notes, Comments, and Abstracts.

BORDERLINE INSANITY.

By JOHN P. STEEL, M.D. EDIN.,
DEPUTY MEDICAL SUPERINTENDENT, ST. LUKE'S HOSPITAL, MIDDLESBROUGH.

RECENTLY there has been a great deal of discussion in the medical and lay press concerning the certification of the insane, and the discussion on the Report of the Royal Commission on Lunacy has brought the matter forward, especially from the point of view of certification. There seems to be no doubt that the present method of certification is to say the least, not quite satisfactory; and the alternatives suggested all bear upon either the early insanities or upon the insanities with a good prognosis.

One of the gravest difficulties at present in dealing with State-aided (or "pauper") patients is that, once a certificate has been fully completed, a stigma is attached to the patient which will, in all probability, remain for the rest of his or her life, and which may prove a very severe handicap in obtaining employment. To the irrecoverable patient it matters little, hard though it may be upon the relatives; but to the patient eventually discharged as cured it is always serious, and sometimes fatal, for the stigma may prevent resumption of the ordinary daily work, and the consequent disability may precipitate another attack. The wealthier sufferer who is able to take advantage of the "voluntary order" system has not the same disadvantage, as a definite mental breakdown can often be avoided by early recognition and treatment. For the bulk of the patients using the public mental hospitals, however, such early treatment, or perhaps prophylaxis, is usually impossible, and the incipient mental breakdown has to be disregarded and the ordinary routine carried out until conduct definitely deteriorates and certification is essential in the interests of the public.

Without overlooking the ætiological significance of mental capability, inherent weakness, &c., many such attacks may be classed as "industrial" insanities, and are due to stress and worry, whilst not a few follow definite malnutrition. Such cases are, in the main, recoverable. The mental attack is analogous to a physical condition, but the treatment is hardly the same at present; the sufferer from chronic nephritis does not undergo any medical or legal process which leaves a stigma for life. The physician alone is responsible and carries out treatment for the restoration of full economic output; indeed, the patient understands the condition and gives willing coöperation in the treatment.

The Fear of the Asylum.

The subject of a mental attack, however, has frequently to be certified because of the potential danger. The patient who has a physical disability consults his doctor as soon as he feels the necessity, because he knows that it is essential; if he is ordered to hospital he is sure that he will obtain help and sympathy from his employers and workmates. The patient with some mental disability, on the other hand, dreads going to a medical man; and if his relatives notice mental symptoms they seldom suggest any medical attention in the early stages, for there is always the shadow of the "asylum" in the background.

This fear of the "asylum" is the reason why so many of the temporary insanities are not treated before certification is essential; no medical man sees the case until it is too far gone for ordinary hospital treatment. In other words, the case has been one of borderline insanity, or has been allowed to lapse into an actual insanity, just because certification is dreaded for its stigma.

Some remedy should be found both for the sake of the patient and for the sake of the mental hospitals. The proposed "provisional certificate" will not inspire confidence either in patients or their relatives, because the latter will still consider that their friend has been "taken to an asylum," and the same difficulty will arise after discharge, whether the certificate is valid for one week or one year. To the ordinary man a certificate is simply a legal tag, stating that a person has been insane, and to most people there is the addendum that the wearer is liable to become violently insane at any time, for the present conception of insanity is that of acute mania.

The Neurological Clinic.

Certification in the great majority of cases is the only right course, but there are many incipient insanities in which there is no real aberration of conduct. These are the cases in which every effort should be made to avoid certification, and perhaps the only way is to educate the public to recognise that insanity does not mean acute mania or acute melancholia alone. How this is to be done it is difficult to say, but the increase in the numbers of "neurological" clinics attached to general hospitals is certainly a great step in the right direction. Many patients have some slight unbalance, not enough for certification but quite sufficient to justify admission to a general hospital for rest or medical treatment.

The great difficulty in this direction lies in the lack of beds for "neurological" cases (using "neurological" as a euphonism for "borderline"), because the bed accommodation in most general hospitals is very severely taxed already. In the larger infirmaries there are small wards for patients requiring special observation (from a mental standpoint), but the majority of the smaller hospitals have no such wards.

The out-patient clinics seem to be the only method of detecting incipient insanities, and it is a great pity that more of general hospitals do not make provision for them. The public have, at present, a confidence in the ordinary hospital which they have not in the mental hospitals, and a patient will willingly accept advice given to him to rest in an ordinary hospital, but will fight very shy of any suggestion that he should attend at a mental hospital either for out-patient treatment or for advice.

As so many of the "industrial insanities" have a very definite physical basis, it should be possible to arrange that certain beds (either existing or to be provided) be available for patients of the "neurological" clinic, in which they shall receive all the medical attention necessary to avert an actual mental breakdown.

A CONFERENCE ON INDUSTRIAL WELFARE.

(FROM A SPECIAL CORRESPONDENT.)

THE conference of the Institute of Industrial Welfare Workers was held this year at Edinburgh, which is becoming so much a centre for meetings of this kind that it has been dubbed "The Geneva of Great Britain." The Hostels Association's splendid accommodation at Craigmillar lends itself readily to vacation congresses of every sort.

The problem of industrial welfare in the technical sense is many-sided. As Mr. JACKSON, speaking as Chief Conciliation Officer, Ministry of Labour, pointed out at the recent meeting, the welfare departments have now passed the pioneer stage and it is possible to have a united and incorporated body of welfare workers. The late war made us familiar with the superintendent of welfare and really established the value of the experiment; and though at first there was a good deal of opposition from labour, the advantages of the system were soon realised—at any rate in the more fortunate munition factories.

Prof. JAMES F. REES (Birmingham) regarded the relation between employers and workpeople as one of the major problems of our time. The basis of this relation was the contract, and at one time this was supposed to be the sum and substance of the whole matter. But the implications of the wage bargain needed to be more carefully explored. Two modern movements converged in the conception of industrial welfare, the first being the desire on the part of the employer to provide something over and above what the law demanded or collective bargaining guaranteed. He might consider more closely the amenities of the factory or he might foster the interest in educational and recreational activities outside factory hours. His actions might have the good or bad attributes of paternalism; for a person who felt the moral urge to do good to others was likely to fail unless he allowed them to coöperate in their own salvation. The second movement was the actual problem of management; what the Americans called "personnel administration." In America there were much more elaborate forms of introducing the worker to the factory than there were in this country. A man should feel that his appointment had been based upon mature consideration and that the firm attached a real importance to the fact that he had been appointed. In Germany, under the new code, firms were forced by law to lay their balance-sheets before the Workers' Council, though they were not forced to explain them. The new German code provided for an appeal to a special court in the case of dismissals.

Prof. WILLIAM MCCLELLAND (St. Andrews) discussed what education could do for industry. Deeply embedded in the traditions of our educational system, he said, was an antithesis between a cultural education for a leisured class able to devote its time to liberal pursuits, and a useful education for the worker. Neither type in its pure form met the demands of a modern society, for now the "leisured" class had to engage in useful work and the "working" class had established their right to higher culture. And the kind of culture given in the so-called cultural courses was not the kind of culture which the modern worker needed. His culture should find points of contact with his everyday

activities and interests if it was to play any really effective part in his life. Much more valuable would be a culture organically related to his vocation and social activities, which would enable him to take an enlightened interest in his work, to understand its scientific basis and its technical and social relationships. Between the two types of education there was a gap to be bridged.

Dr. DAVID MCKAIL (Factory Surgeon, Glasgow) discussed the maintenance of health in industry. It demanded, he said, the coöperation of worker, employer, and the State. The necessary expenses should be a first charge on profits. In all the large factories a personnel department was a necessity from every point of view. This department must have a definite executive power in its own field and an allotted place in the councils of management of the factory. There was little use of a welfare system where the recommendations based on the experience gained were ignored or relegated to the indefinite future. Ventilation with pure fresh air was comparatively easily effected by the expenditure of power, and therefore with a definite oncost. To depend on natural forces for ventilation was to invite failure. Lighting of factories should be sufficient to prevent accident, eyestrain, and glare, and to encourage cleanliness. The inhalation of large quantities of any dust, whether poisonous or not, was unhygienic. A considerable amount of chronic disablement among workers was due to this cause, although not easily brought home to the industry concerned, as some of the affected workers drifted to other employment or, in the case of women, got married, so that the ultimate effects were lost sight of. The action of noise in impairing efficiency was not well understood. There could be no doubt that just as in time it impaired the hearing (e.g., in boiler-makers), it must cause a disturbance of the nervous centres which, in some persons, might have harmful results. Here, again, final results were lost sight of owing to the fact that people who found noise incommoding drifted into other occupations. Then there was the question of excessive speed of work. In the old non-mechanical days each individual made his own pace or rate of working and each came to be characterised as fast or slow. With machinery, the pace was uniform to a great degree. In the textile trades the worker could stop the machine as required. Some found that the steadiness needed to "make a pay" under the eight hours' day was a strain and that the bad old ten hours' day enabled them to take "rests" and feel more comfortable. Certainly the "rests" mode was more hygienic. As there was a minimal production insisted on for an individual, so there should be a maximum production determined for each process on physiological grounds so as to regulate the pace and amount of work put out in a given time. Because a person was speedy that was no reason why he should be allowed greatly to exceed the minimal rate of working and output. Such voluntary speeding-up on the part of employees was likely to have disastrous results in nervous breakdowns, rheumatoid arthritis, and other serious complaints. Dr. McKail's careful paper, prepared on the basis of extended study and practice as a factory surgeon, made a great impression on the conference.

Mr. LONGMUIR (Glasgow, President of the Scottish Society of Welfare Supervisors) exhibited a chart showing that March was the worst month for sickness. This is in accord with general knowledge. At present in Scotland, he said, they had only one holiday in spring and yet they had a week or so at New Year. He suggested that two days were ample at New Year and the balance should be added to Easter or the spring holiday. The New Year holidays were a relic of the days when each factory raised its own steam for power purposes and a week was required to clean the boilers. Under modern conditions that was no longer necessary.

Dr. MCKAIL said that there was a bigger strain on workers in the winter and the strain seemed to tell in March. He agreed that there should be an increased gap at Easter.

Mr. WILLIAM GRAHAM, M.P. (member of the Medical Research Council), dealt at the closing session with the place of industrial welfare in the community. He said that welfare work had to look constantly to the problems of industry at large so that the smallest scheme within the individual factory might have a definite ideal and direction. Much of the British reorganisation of industry on the purely public side was less effective than that undertaken in America or Germany. That tended to give these countries an advantage over Great Britain in export markets and America was able to make that advantage real even within the British Empire, as in the supply of motor-cars to Australia. Industrial welfare work of large vision would look to these problems. Further, industrial welfare work frequently suffered from suspicion as to motive. Many employers still regarded it as the beginning of interference with their freedom of control. On the other hand, many workers doubted whether they would have their place in the beneficial results of the increased efficiency under such schemes. No one disputed that greatly increased efficiency was necessary and urgent.

A HOME FOR CHILDREN WITH RHEUMATIC HEART DISEASE.

THE original "Heartsease" home at West Wickha for children suffering from rheumatic heart disease, w acquired by the Invalid Children's Aid Association in t autumn of 1926, the first 28 patients being admitted April of this year. On Oct. 6th an extension was oper by Lady Lennard, the additional accommodation havi been made possible by gifts from King Edward's Hospi Fund for London and the Ancient Order of Froth Blowe which, as Sir Alfred Fripp explained, has provided 17 c with an endowment of £500 each.

Sir Charters Symonds, chairman of the Invalid Childre Aid Association, said that the home was not a convalesc home in the ordinary sense, but a treatment centre children with a prospect of recovery, and a place for resea into the cause and prevention of heart disease. Child suffering from rheumatic affections of the heart requi a prolonged rest, often beginning with a considerable per in bed, and it required no great imagination to see t they would not be happy in homes with other children whose games they must not take part. The Associat had had the distinction of providing the first special ho for children with heart disease seven years ago, a sec home following four years later. The "Heartsease" ho was to replace the second home, the lease of which h expired. The open-air ward might be regarded as the lat thing in modern construction of this kind. Special gratitu was due to Sir Henry Lennard, by whose generosity waiving certain building restrictions the erection of ward had been made possible, and the friendly recept given to the project by residents of the district had ad greatly to the pleasure of carrying out the work.

A SUCTION PIPETTE.

THE micromethod of Linzenmeier for the determinat of the sedimentation time of the red cells has secured gen adoption. This method involves the mixture of a kn quantity of blood and of citrate solution in the bulb special pipette. After being mixed in the bulb the mixt is blown into the stem and the red cells allowed to sedim All those who have used this method have experienced annoyance of having sucked too hard and thereby dr the citrate-blood mixture beyond the bulb or of hav blown too hard and lost the mixture. Dr. Jacques Steph of Montana, has devised a simple modification which be a boon to all those who have experienced these trou To the end of the pipette at which suction is applied Stephani attaches a length of vaselined rubber pres tubing, to the other end of which is applied an ordi glass tap. Suction is produced by closing the tap sliding the rubber tube up the pipette. The suction ca stopped immediately when citrate solution and blood h entered the bulb of the pipette by opening the tap. A the blood and citrate solution have been mixed the ta again closed and the blood forced into the stem of the pip by movement of the rubber tubing along the stem of pipette in the reverse direction. Dr. Stephani apologises describing such a simple expedient in print, but the th of all who use this method and have not hit upon some similar device are due to him.

WANTED, A SKELETON.

THE matron of an excellent charity would be grat if any reader of THE LANCET would give her a skele in a sufficiently perfect condition to make clinical lect intelligible to the nurses of an obstetric hospital. If an is able to assist the matron we shall be happy to put hi communication with her.

A PHILOLOGICAL IMPOSSIBILITY.

To the Editor of THE LANCET.

SIR,—May I allude to the incorrect spelling of my n in your issue of Oct. 8th (pp. 764, 765)? The n "Heffernan," or more fully, "O'Heffernan," is the Anglic form of the Gaelic "Ua h- Eichthighearnán," mea literally "descendant of the horse-lord." There are "O'Heffernans," and at least six "Heffernans" on Medical Register. The spelling "Hefferman" is philologi impossible, and always incorrect.

I am, with apologies for troubling you,
Yours faithfully,
P. HEFFERNAN,
Major, I.M.S. (ret.); Tuberculosis Offic
Oct. 10th, 1927. Derbyshire County Council.

*** We much regret the error, though it has broug this interesting note.—ED. L.

[1] Schw. med. Wochenschr., 1927, xxxii., 765.

Harveian Oration

ON

GILBERT, BACON, AND HARVEY.

Delivered before the Royal College of Physicians of London on Oct. 18th, 1927,

BY SIR WILLIAM HALE-WHITE, K.B.E., M.D. LOND. & DUB., LL.D. EDIN.,
CONSULTING PHYSICIAN TO GUY'S HOSPITAL.

THERE are two reasons why Harvey should be placed in the select class of really great men. One is because he discovered that the blood circulates, being compelled to do so by the contraction of the heart; the other, even more powerful, is because he was among the earlier scientists to show the value of properly conducted experiment.

Every man's mind is compounded of what is born within him, modified by impressions received from without. Therefore it is of interest to see who were the men around Harvey who might have influenced him. At Padua there were his teachers; many Harveian orators have dealt with this part of his life, but I propose to see if any of his own countrymen, perhaps without his knowledge, can have helped to mould such of his thoughts as led to his great discovery. I shall make many quotations, but this, I trust, you will pardon, first, because, in any argument it is necessary that the premises should be precise; secondly, because the language of Bacon is like music to the ear.

Inasmuch as Harvey and Francis Bacon—commonly called Lord Bacon, which is altogether wrong, for his titles were Baron Verulam of Verulam and Viscount St. Alban—were contemporaries, we must consider whether it is likely that he swayed Harvey. The life of Bacon is a fascinating story, but lack of time forbids my saying anything about it which is not germane to my purpose.

THE ADVANCEMENT OF LEARNING.

Harvey published his discovery of the circulation of the blood in 1628, and tells us that he had, for nine years and more, in his lectures, confirmed these views by multiplied demonstrations in your presence, illustrated them by arguments, and freed them from the objections of the most learned and skilful anatomists." His first mention of it is in his notebook dated 1616. "The Two Bookes of Francis Bacon of the Proficience and Advancement of Learning Divine and Humane," were first published in 1605, when Harvey was 27 years old, 23 years before the publication of his book and several years before he made his discovery. "The Advancement of Learning," "the first great book in English prose of secular interest" (Church), had many readers, for three editions quickly appeared. When his "Instauratio" was issued Bacon sent the King a copy, with a letter saying he thinks it will find many readers "because near my former book of the *Advancement of Learning* is well tasted in the Universities here, and the English colleges abroad; and this is the same argument in ink deeper." [1] The "Advancement," which we thus see was widely read in the years immediately following its publication, implores those who wish to delve into the secrets of nature to discountenance mere authority and not blindly to believe what they are told, but to seek knowledge for themselves by observation and experiment; it teaches how properly to use induction, it points out the hopelessness of the false methods of reasoning commonly used, it has much in it about medicine. It is a noble work, devoted to the lofty purpose of increasing knowledge, its language is so beautiful and dignified that it may be placed second to that of Shakespeare.

The first book contains an oblation to James I., because Bacon longed to persuade the King to be interested in learning. In this he failed, as he had with Elizabeth.

Passing to the second book I will, by direct quotation,[2] try to convince you that the "Advancement of Learning," so immediately popular that Harvey must have known of it, would have appealed to him. Much of the argument is directed to show that a reform of method in the pursuit of knowledge is necessary. Thus:

"For as things are now, if an untruth in nature be once on foot, what by reason of the neglect of examination and countenance of antiquity, and what by reason of the use of the opinion in similitudes and ornaments of speech, it is never called down." [3]

"For the handling of final causes mixed with the rest in physical inquiries, hath intercepted the severe and diligent inquiry of all real and physical causes . . . . to the great arrest and prejudice of further discovery . . . . and have brought this to pass that the search for Physical Causes hath been neglected and passed in silence." [4]

"It being the nature of the mind of man (to the extreme prejudice of knowledge) to delight in the spacious liberty of generalities and not in the enclosures of particularity." [5]

"Where there is much controversy there is at many times little enquiry." [6]

"They hastened to their theories and dogmaticals and were imperious and scornful towards particulars." [7]

Next listen to a few quotations illustrating Bacon's plea for the experimental method:

"I find some collections made . . . . but commonly with a rejection of experiments familiar and vulgar. For it is esteemed a kind of dishonour unto learning to descend to inquiry upon matters mechanical" [8] (or as we should say now-a-days, experimental).

"All true and fruitful Natural Philosophy hath a double scale or ladder, ascendent and descendent; ascending from experiments to the invention of causes and descending from causes to the invention of new experiments." [9]

"Those experiments be not esteemed which have an immediate and present use, but those principally which are of most universal consequence for invention of other experiments,[10] the use of History Mechanical" (i.e., experimental) "is of all others the most radical and fundamental towards natural philosophy." [11]

Then there is a fine passage emphasising the value of experiment, too long to quote in full, it begins:

"But here was their chief error; they charged the deceit upon the senses, which in my judgment are very sufficient to certify and report truth, though not always immediately, yet by comparison, by the help of instrument." [12]

Nowadays, it is at last recognised that those who spend their lives investigating Nature should be paid. Bacon anticipated us, saying—

"There will hardly be any main proficience in the disclosing of Nature, except there be some allowance for expenses about experiments . . . . and therefore as secretaries and spials of princes and states bring in bills for intelligence, so you must allow the spials and intelligencers of Nature to bring in their bills, or else you shall be ill advertised." [13]

The "Advancement" tells us that medicine "is a most noble art," its object being "to tune this curious harp of man's body and reduce it to harmony." The author pities the physician for he is judged by the event—

"which is ever but as it is taken; for who can tell if a patient die or recover . . . . whether it be art or accident? And therefore many times the impostor is prized and the man of virtue taxed. Nay we see the weakness and credulity of man is such, as they will often prefer a mountebank or witch before a learned physician." [14] Consequently physicians say to themselves: "If it befall me as befalleth to the fools, why should I labour to be more wise." [15]

Bacon criticises the doctors of the day quite fairly; he finds that comparative anatomy, physiology, and morbid anatomy are not studied as they should be, that no use is made of vivisection, and that if—

"a man look into their prescripts and ministrations, and he shall find them but inconstances and every day devices without any settled providence or project." [16]

His attitude to medicine is shown in the sentence:

"There is one thing still remaining which is of more consequence than all the rest—namely, a true and active Natural Philosophy for the science of Medicine to be built upon" [17]

and his attitude to science may be summed up in two sentences:

"And this is the very thing which I am preparing and labouring at with all my might, to make the mind of man

by help of art, a match for the nature of things [18] . . . . when he uses some direction and order in experimenting, it is as if he were led by the hand." [19]

Surely, after these extracts, we must believe that Bacon's own physician, Harvey, was influenced by his patient's book which was widely known, was published some years before Harvey began his researches, contains much about medicine and preaches reform of method and the use of experiment, in both of which Harvey's strength lay. I do not like to think that he was so ill-educated as not to have followed Shakespeare and other learned people in the reading of the "Advancement," by the author of the already popular Essays, for his contemporary, Ben Jonson, in a review of the great English writers, says of him "he who hath filled up all numbers, and performed that, in our tongue may be compared or preferred either to insolent Greece or to haughty Rome," [20] and in these days we have Abbott speaking of Bacon's unique mastery of the English language. Remember, these words are said of a man writing at the time of Shakespeare and the Authorised Version, and then we get a measure of Bacon's greatness as a writer.

Another work of Bacon's that must have been known to Harvey, before the making of his discovery, is "De Sapientia Veterum," issued in 1609; it was much appreciated and was soon reprinted and translated. Its general trend is welcome to a man well disposed towards experiment, for the proper investigation of Nature is recommended in it.

THE NOVUM ORGANUM.

In 1620 a book was published which began thus:

"*The Great Instauration. Pro-œmium.* Francis of Verulam reasoned thus with himself and judged it to be for the interest of the present and future generations that they should be made acquainted with his thoughts." [21]

He tells us that the human intellect makes its own difficulties, and hence ignorance and mischiefs innumerable. Therefore the author is "to commence a total reconstruction of sciences, arts and all human knowledge." [22] Lest he should die before the work is finished, it was to be published in six parts. The first, which appeared after the second, was "De Augmentis." The second, issued in 1620, was the "Novum Organum," not quite completed. Only fragments of some of the other parts were ever written; Bacon calculated that his work when finished would be sixfold as voluminous as Pliny. If this estimate is correct we only have one-twentieth of the whole.

The "Novum Organum" has all the beauties of the "Advancement"; it is a masterpiece of condensed writing, without a word too many, and each word precisely right. As with the "Advancement," I will give extracts which will show that it also is just such a book as would help to form a mind like Harvey's. In the "Plan" introducing us to the "Novum Organum" we find this:

"The subtlety of experiments is far greater than that of the sense itself. I contrive that the office of the sense shall be only to judge of the experiment and that the experiment shall judge of the thing." [23]

"Those, however, who aspire not to guess and divine, but to discover and know; who propose not to devise, and mimic fabulous worlds of their own, but to examine and dissect the nature of this very world itself; must go to facts themselves for everything." [24]

In the preface is this eloquent exhortation:

"But if any man there be who . . . . aspires to penetrate further; to overcome, not an adversary in argument, but nature in action; to seek, not petty and probable conjectures but certain and demonstrable knowledge with me, that passing by the outer courts of nature which numbers have trodden, we may find a way at length into her inner chambers." [25]

In the "Novum Organum" itself we are warned not to pin our faith to the syllogism, for the premisses being only words, often there is no firmness in the superstructure, our only hope lies in a true induction; we are reminded that we can only progress by t study of particulars. We are told that—

"it is the peculiar and perpetual error of the hum intellect to be more moved and excited by affirmati than negatives; whereas it ought properly to hold its indifferently disposed towards both alike." [26]

"What a man had rather were true he more read believes." [27]

We suffer from "the mischievous authorities of syste which are founded either on common notions or on a f experiments or on superstition." [28]

Then follows advice to physicians to renounce varieties of false reasoning, for—

"the entrance into the kingdom of man, founded on sciences, being not much other than the entrance into Kingdom of Heaven, whereunto none may enter except a little child." [29]

"The manner of making experiments which men now is blind and stupid." [30]

"Men are inclined to turn aside from their experime for some practical application of them, like Atalanta, t go aside to pick up the golden apple and let victory esca them, they should seek for experiments of light, not experiments of fruit." [31]

A few pages further on we find this beauti passage:—

"And an astonishing thing it is to one who rightly c siders the matter, that no mortal should have seriou applied himself to the opening and laying out of a road the human understanding direct from the sense, by course of experiment orderly conducted and well built but that all has been left either to the mist of tradition, the whirl and eddy of argument, or the fluctuations and ma of chance and of vague and ill-digested experience." [32]

"No one has yet been found so firm of mind and purp as resolutely to compel himself to sweep away all theo and common notions and to apply the understanding t made fair and even, to a fresh examination of particulars.

"A greater abundance of experiments is to be sought and procured." [34]

Then, to magnify the dignity of investigation, Bac quotes the proverb of Solomon:

"The glory of God is to conceal a thing; the glory of king is to search it out." [35]

Bound up with the first edition of the "Nov Organum," Bacon published a "Description of Natural and Experimental History such as may se for the foundation of a True Philosophy." The int duction contains some of his most magnificent writi Listen to this from it:—

"Meanwhile what I have often said I must here emph cally repeat; that if all the wits of all the ages had or shall hereafter meet together; if the whole human had applied or shall hereafter apply themselves to Ph sophy, and the whole earth had been or shall be nothing academies and colleges and schools of learned men; without a natural and experimental history such as I going to prescribe, no progress worthy of the human could have been made or can be made in philosophy the sciences. Whereas, on the other hand, let such a hist be once provided and well set forth, and let there be ad to it such auxiliary and light giving experiments as in very course of interpretation will present themselves . . For in this way and in this way only, can the foundation a true and active philosophy be established; and then men wake as from a deep sleep, and at once perceive w a difference there is between the dogmas and figment the wit and a true and active philosophy, and what i in questions of nature to consult nature herself." [36]

One more quotation from the same source I can resist:

"Away with antiquities and citations or testimonie authors." [37]

WAS HARVEY INDEBTED TO THE "NOVUM ORGANUM"?

But some may say all this is beside the mark, before these two books appeared in 1620, Harvey, about four years, had been teaching that the bl circulates. Thus, in a leading article in the *Bri Medical Journal*, we find "a comparison of d shows that Harvey could not owe anything to "Novum Organum." [38] On the face of it this app a fair inference, but it is probably incorrect bec of the following considerations. The most trustwo

ccount we have of Bacon is that by his chaplain, awley, who says:

"His book of the *Instauratio Magna* . . . was the oduction of many years' labour and travel. I myself have en at least 12 copies of the *Instauration* revised year by ar one after another, and every year altered and amended the frame thereof, till at last it came to that model in hich it was committed to the press . . . he would often k if the meaning was expressed plainly enough." [39]

Further, many tracts, which are trials for the great ook, were found among Bacon's papers after his eath. Some were written as early as 1603–1605. need not name them as they can all be found in The Works of Francis Bacon." A quotation from e "Cogitationes" will suffice:

"And it were shame that men should have examined so refully the tinklings of their own voice and should yet so ignorant of the voice of nature." [40]

We see, therefore, that for many years before the ublication of the "Novum Organum," and before arvey began his experiments, Bacon's mind was uch occupied with it, that he worked hard at it, aking numerous trials; he certainly talked about with his chaplain, consequently it is likely that he lked about it with his physician, of whom, as we all see presently, he probably saw much, for there as no secret about Bacon's philsoophical work; he vited criticism from several friends; many had ready read the "Advancement" published earlier; often spoke of his desire to study; it was well own how he busied himself in his leisure. We can rdly err if we conclude that not only the thoughts pressed in the "Advancement," which we have en Harvey had ample opportunity of reading before began his experiments, but also those which nmered in Bacon's brain between the publication of is work and that of the "Novum Organum," in nich they were embodied, were known to and affected arvey, to whom they would have been particularly ngenial, for he became one of the greatest of scoverers because he experimented and disregarded ere authority.

Effect on Science of Bacon's Teaching.

If I have carried you in unison with me so far, you e with me in thinking that Bacon's teaching touched e mind of Harvey; still, it will be an advantage to if this opinion is strengthened by what others have ought of the position of Bacon's writings in the story of science. Aristotle and Leonardo da Vinci d experimented; several others, such as Albert the eat, Vanini, Campanelle, and Ramon Lull, as may seen in Prof. E. A. Peers's recent translation of anquerna,[41] saw that mere authority was allowed to erride reason. Roger Bacon had laid down precepts at might have guided men aright, but, so abstract d dogmatic was the ordinary teaching up to the ne of Francis Bacon, that these examples bore little ut, being stifled under the mass of theological, taphysical and commentatorial literature with which e Middle Ages abounded. It was Francis Bacon o caused this deadening fog, which bemused all ginality, to roll back when he directed men to card authority and to seek out nature by proper servation, proper reasoning, and proper experiment. ople of his own time saw this. Rawley says: "If ere was a beam of knowledge derived from God upon y man in these modern times, it was upon him."[42] ter Heylen, who was a young man when the Great nstauration" was first published, tells us—

"The Lord Chancellor Bacon was a man of most strong ain and a chymical Head . . . . Pity it was, he was not ertained with some liberal salary, abstracted from all airs both of Court and Judicature, and furnished with fficiency both of Means and Helps for the going on of Design. Which had it been, he might have given us such body of Natural Philosophy, and made it so subservient the public good, that neither Aristotle, nor Theophrastus ongst the ancients, nor Paracelsus or the rest of our ter chymists would have been considerable." [43]

Sprat writes:

"I shall only mention one Great Man who had the true agination of the whole extent of this Enterprise, as it is now set on foot; and that is, the Lord Bacon . . . . His Genius was searching and inimitable." [44]

The enterprise was the foundation of the Royal Society, and it is generally allowed that it was Bacon's "New Atlantis" and the thoughts inspired in others by him which led to the foundation of not only the Royal Society, but also of several foreign scientific associations. Metaphysical Cowley in his poem to this Society writes thus:

> "Bacon, like Moses, led us forth at last,
> The barren Wilderness he past,
> Did on the very Border stand
> Of the blest promis'd Land,
> And, from the Mountain's top of his exalted Wit,
> Saw it himself and showed us it." [45]

So much for the past opinion of Bacon's influence. During three centuries it has remained unchanged. We find Leibnitz [46] remarking—

"We do well to think highly of Verulam for his hard sayings have a deep meaning in them."

Whewell [47] mentions no other author in his preface and begins his book with a quotation from Bacon, and Macaulay writes that Bacon "moved the intellects which moved the world." Space allows me to quote only two modern writers. Prof. Thomas Fowler [48] tells us—

"What Bacon says of Plato is pre-eminently true of himself, he was 'a man of a sublime genius who took a view of everything as from a high rock.'"

He popularised and dignified experimentation and the study of nature.

"It would hardly, I think, be an exaggeration to compare Bacon in the intellectual sphere, with Luther in the sphere of religion."

Church [49] writes that Bacon—

"had the brightest, richest, largest mind but one, in the age which had seen Shakespeare and his fellows."

Later on he says:

"in temper, in honesty, in labour, in humility, in reverence he was the most perfect example that the world had yet seen of the student of nature, the enthusiast for knowledge."

In the introduction to Fowler's edition of the "Novum Organum" will be found a long list of testimonies by many writers to the extraordinary power that Bacon's teaching has had upon scientific thought and production. The chief claim that Bacon made for himself is quaintly expressed in the letter he wrote to Dr. Playfer:

"I have only taken upon me to ring a bell to call other wits together, (which is the meanest office) it cannot but be consonant to my desire, to have the bell heard as far as can be." [50]

Truly its peal has been heard all over the world and has reverberated for three centuries, and surely these references suggest that Harvey must have heard its call.

Bacon's Personality.

Having shown that Bacon's teaching was available to Harvey, was well known while he was a young man, and would be attractive to him, let us see whether the last is true also of Bacon's personality. Nobody is more likely to know him well than his secretary, Meautys, and his chaplain, Rawley. Both were devoted to him, and the first says his sole ambition is to grow up only under his Lordship and come what may to serve him with his life and fortune, laying down all he has at his feet.[51] The second shows us that Bacon must have been a delightful conversational companion.

"His meals were refections of the ear as well as of the stomach . . . . wherein a man might be refreshed in his mind and understanding no less than in his body . . . . In which conversations . . . . he was no dashing man, as some men are, but ever a countenancer and fosterer of another man's parts. Neither was he one that would appropriate the speech wholly to himself, or delight to outvie others, but leave a liberty to the co-assessors to take their turns." [52]

Tobie Mathew, son of the Archbishop of York, says of Bacon—

"It is not his greatness I admire, but his virtue. It is not the favours I have received of him that have enthralled and enchained my heart, but his whole life and character; which are such, that, if he were of an inferior condition, I could not honour him the less, and if he were my enemy I should not the less love and endeavour to serve him." [53]

Ben Jonson tells lovingly of his virtue and thus of his speech—

"No man ever spake more neatly, more pressly, more weightily; or suffered less emptiness, less idleness, in what he uttered . . . . No man had their affections more in his power. The fear of every man that heard him was, lest he should make an end." [54]

His secretary and apothecary, Boener, hoped that a statue of him would be put up, not because of his learning, but on account of his being "a memorable example to all of virtue, kindness, peacefulness and patience." [55]

We know a man by his friends. Bacon drew them from everywhere. There were many abroad and in this country Essex, Buckingham, Lancelot Andrewes, Selden, Bodley, Hobbes, Jonson, Mathew and George Herbert the poet who helped in the translation of the "Advancement" into Latin and who wrote verses in praise of Bacon who in his turn dedicated his versification of the Psalms to Herbert saying he was his affectionate friend. Bacon had few enemies, the chief was Coke, his professional antagonist. He was popular, as we learn from the fact that when he took his seat as Lord Keeper, besides the servants, the Judges and the Inns of Court, he was accompanied by most of the nobility, with other gallants to the number of 200 horse.

All this shows him to have been a lovable charming person with whom everybody would enjoy talking, and it is incredible that his physician did not converse with him and that he was ignorant of his teaching.

BACON'S HEALTH.

On the whole, Bacon's health was good; nevertheless he was a chronic dyspeptic, giving considerable thought to his symptoms and indulging abundantly in aperients. He has left us very particular accounts of how he took these and how they acted. [56]

In 1617 he had an illness thought to be gout, but it only lasted a few days. A contemporary letter [57] says, "he hath so tender a constitution both of body and mind that he will hardly be able to undergo the burden of so much business." This surmise was incorrect, for during the next four years Bacon worked very hard. Two years later he was away from work for a time probably owing to an attack of stone "which held him in great pain two or three days." [58] That he was very fond of taking medicine is shown by these and other references and by a letter written in 1623, which is of interest as having to do with the separation of the Company of Potycaries from that of Grocers; in it he says, "You may perhaps think me partial to Potycaries, that have been ever puddering in physic all my life." [59]

Bacon depended on his physician. When he was let out of the Tower he was not allowed to come within the verge of the Court, and thus he could not live in London. In some moods he thought the Tower preferable to such liberty, for he wrote in his petition to the House of Lords, "there I could have company, physitians," and he said the same in two letters to Buckingham, to whom, in a letter two years later, he again speaks of his physicians, whom he calls strange creatures. It is difficult to conceive a patient more likely to consult his physician frequently than one who was a chronic introspective dyspeptic, rejoiced in purgatives, had gout and a stone, especially as we have just seen that this patient was one with whom the physician would have delighted to talk, and many statements in Sylva Sylvarum suggest that Bacon often discoursed with doctors.

Further, apart from the relationship of patient and physician, Bacon and Harvey must have seen much of each other, for London was no bigger than a large provincial town of the present time, both move among the Court and nobility and both were in th small class of the well educated.

HARVEY'S MIND SIMILAR TO BACON'S.

I have now finished with what may be called th Baconian side of my argument. The Harveian sid will be much shorter. The philosopher said observ and experiment properly, deduce scientifically, withou attention to mere authority; no one could have don this more rigorously than the physician, whose min was in this matter the counterpart of that of th philosopher, for Harvey said to Ent—

"I have oftentimes wondered and even laughed at tho who have fancied that everything had been so consummate and absolutely investigated by an Aristotle or a Galen some other mighty name that nothing could by an possibility be added to their knowledge." [60]

In the introduction to his work on the "Generatio of Animals," he writes:

"Without the due admonition of the senses, witho frequent observation and reiterated experiment, our min goes astray after phantoms and appearances."

Further on:

"The method of investigating truth commonly pursu at this time therefore is to be held erroneous and almo foolish, in which so many inquire what others have sai and omit to ask whether the things themselves be actual so or not."

Or to take a passage from the introduction "De Motu":

"It will be proper to look more narrowly into the matte to contemplate the motion of the heart and arteries, not on in man, but in all animals that have hearts; and furth by frequent appeals to vivisection, and constant ocul inspection, to investigate and endeavour to find out truth

Really, except that the language has not the migh grandeur of that of Bacon, it might be he writin So do the minds of Bacon and Harvey jump togeth that we are constrained to believe that the eld influenced the younger, particularly when we recolle the other reasons already given for this belief.

VALUE OF EVIDENCE THAT HARVEY WAS NOT INFLUENCED BY BACON.

The view here put forward of the relationsh between them is not that held by many write several of whom speak of Harvey's contempt f Bacon, or state that he can owe nothing to hi Those who maintain the last have forgotten t "Advancement" and the history of the "Novu Organum." All who profess the first base it on t following. Aubrey [61] tells us—

"He (Harvey) had been physitian to the Lord Chancel Bacon, whom he esteemed much for his witt and style, b would not allow him to be a great philosopher. 'He wri philosophy like a Lord Chancellor' said he to me, speaki in derision; 'I have cured him.'"

Assuredly this anecdote does not justify the bel that Harvey was not affected by Bacon. Aubrey te us that it was not until 1651 that he became acquaint with Harvey, who was then 73 years old. Aubre statement is probably muddled for, as Bacon had be dead 25 years, Harvey most likely said "he wrot and for the same reason should have said "I cur him," and Aubrey does not make it clear whet Bacon was cured of a bodily ailment or of writi philosophy like a Lord Chancellor. Harvey, w according to Aubrey was very cholerique and w certainly aged, was speaking of a patient dead 25 ye before and, being cholerique, may easily, for m argument's sake, have taken the other side to Aubr in not allowing Bacon to be a great philosopher, a we must also remember that even if this were Harve deliberate opinion, others have thought so too, b have, nevertheless, considered that Bacon did m than anyone to point the way to the proper mode scientific research. We only have Aubrey's statem that Harvey spoke in derision of Bacon's way writing, but even if he did, he can only have mea

hat Bacon wrote in a stately, dignified, perhaps rather ontifical way; if he meant anything else he was ery foolish, for, as already shown, it was allowed hen Bacon was alive, and has been ever since, that ew can match his prose. Certainly there is nothing this story to suggest that Bacon did not influence Harvey; indeed, it is the other way, for he must have ead the philosopher before he could give an opinion as how he wrote, and we are told he esteemed his isdom and style.

But quite apart from this argument there is another ason why we should not pay any attention to this necdote—namely, that Aubrey is quite unreliable. e did not begin his "Lives" till 1680, when he put ch name in a book, then under it, when anything me into his head, he wrote hastily, without reference notes, his recollections of the person; this was sually done in the morning, often in the midst of ckness following a night's drunken debauch and rely revised. Harvey had been dead 23 years when is oft-quoted tale of what he said about Bacon, ho had been dead 50 years, was jotted down in this anner by a gossiping drunkard, who owns that he rote "tumultuarily." Look at it as we may, it is orthless as evidence as to what sway Bacon had over arvey. Indeed Andrew Clark, Aubrey's editor, says Aubrey's 'Lives' supply an inviting field for com- ent, correction and addition. But, even so treated, ey will never be a biographical dictionary. Their value s not in statement of biographical or other facts." [62]

It has been implied that, because Harvey is where mentioned by Bacon, we may infer that the o were not in accord. In a note-book of Bacon's der the date July 26th, 1608, he says he must ask r opinions about his scientific work from the ysicians Poe, Paddy, and Hamond, but there is thing to show that he ever did this. He would rdly have asked Harvey for he was then only years old and probably was, at that time, unknown Bacon.[63] I have looked through everything he rote, and it is clear that he was interested chiefly physical science, especially astronomy, but hardly all in physiology. Many phrases having a physio- gical bearing are to be found in his writings, but ey are all curious isolated statements, if an explana- n of them is given it is not Bacon's he merely produces the popular explanation. He collected ndreds of these statements for future investigation. st we now know to be fantastic nonsense.

"De Motu" was published in 1628; Bacon died in 26. Therefore he could not have alluded to the ok. Harvey in his Lumleian lectures began to ch his new views not earlier than 1616. But there no evidence that Bacon was ever present at these tures; indeed, from 1616 to 1620 he was at the very siest part of his career, and he certainly had no time n to attend lectures or to pay much attention to mours which might come to him saying that a great scovery had been made, especially as Harvey's periments were then unconfirmed; indeed, if con had asked doctors he would probably have n told that the new doctrines were nonsensical, for know that many of the medical profession did not nk Harvey's views worthy of discussion. So far m its being surprising that there is nothing in the "Novum Organum," published in 1620, about rvey's discovery which he began to teach, but only ally, some four years before, it would have been onishing if there had been anything.

In "The History of Life and Death," published in 23, Bacon says, "the blood is that which irrigates juices and membranes" and "the blood of the ins supplies the blood of the arteries." [64] It might thought that these sentences show that he knew nething of the circulation of the blood, but my strong inion, judging by the context, is that he still knew thing about it. Nor is this to be wondered at, for con, after his release from the Tower in 1621, lived onely life away from London, and so would not hear Harvey's lectures. To sum up, the neglect of Bacon mention Harvey is easily explained, and is of no lue as indicating that the two were antipathetical.

It may be said that I have brought forward no direct proof of any influence of Bacon on Harvey; all my evidence is circumstantial. But two things are to be remembered: first, circumstantial evidence is often much stronger than direct; secondly, how little we know of the daily doings of people who lived 300 years ago. Over and over again there is a reference in a letter to something Bacon had on hand, but of the outcome of which we are completely ignorant. Spedding writes:—

> "It is singular that of two men so remarkable in their several ways as Bacon and Coke, whose fortunes, objects, tastes, ideas, and dispositions crossed each other at so many points, and whose business must have brought them so continually into company and so frequently into conflict, the personal relations should be so little known. No anecdotes have been preserved by the news writers of the day which enable us to form a clear idea of their behaviour to each other when they met,—the style of their conversation, or the temper of their courtesies." [65]

This being so, it is not strange that we have no direct proof of Bacon's influence upon Harvey.

GILBERT'S INFLUENCE.

Everything goes to show that Harvey was regarded with affection by his own profession. He speaks of his "very dear friend Dr. Argent," we know of Ent's tenderness for and admiration of him, of Prujean's esteem for him. His generosity to this College tells us that the Fellows of it were his friends whom he much loved, but there is no indication that among these medical friends there was anyone of sufficient originality to help to mould Harvey's thoughts, with a single exception, namely, William Gilbert, one of the great original geniuses among the famous Elizabethans.

He was born in 1540 at Colchester, went to Cambridge, took his M.D. there, became a Fellow of St. John's, travelled abroad, settled to practise in London in 1573, ultimately living in Wingfield House, Peter's Hill. Sylvanus Thompson's [66] statement that his relations with English physicians were intimate and extensive must be correct, for Gilbert held several offices at this College, becoming President in 1600. He was well known outside his profession, for he attended many celebrated people and was physician to Queen Elizabeth; the story that she left him a legacy shows her liking for him. Gilbert and Dr. Lancelot Browne, in 1584, together signed a medical certificate which is preserved in the Records Office; in 1588 both were selected to advise the Privy Council about the health of the Navy, and Browne held various offices at the College of Physicians, so, in one way and another, he must have known Gilbert intimately. Lancelot Browne's daughter married Harvey in 1604. Gilbert died in 1603. Considering the close acquaintanceship between Gilbert and Browne, Harvey must have heard much of the first and quite likely he met him when he was courting; anyhow, it appears that he knew a good deal about him, for Sylvanus Thompson tells us that "according to Harvey, Gilbert expended no lesser sum than five thousand pounds on his researches." Therefore we may conclude that, for both professional and family reasons, Harvey would be inclined to pay attention to anything Gilbert said.

Gilbert's outstanding position is due to this—he broke away from tradition, he challenged authority, he went to Nature herself, investigating her by experiment, and he employed proper inductive reasoning. The first words in the preface of his famous book on the magnet are:—

> "In the discovery of secret things and in the investigation of hidden causes, stronger reasons are obtained from sure experiments and demonstrated arguments than from probable conjectures and the opinions of philosophical speculators of the common sort; . . . . But if any see fit not to agree with the opinions here expressed and not to accept certain of my paradoxes; still let them note the great multitude of experiments and discoveries; these it is chiefly that cause all philosophy to flourish; and we have dug them up and demonstrated them with much pains and sleepless nights and great money expense." [67]

This book made Gilbert the father of experimental philosophy in this island; it is the earliest known work treating of both magnetism and electricity; few finer examples of inductive reasoning have ever been presented to the world; there is abundant testimony that it produced a deep impression, not only in this country, but throughout the civilised universe: it places Gilbert on a level with Harvey, Galileo, Gassendi, and Descartes.[68] Galileo says:

"I extremely praise, admire, and envy this author for that a conception so stupendous should come into his mind. I think him moreover worthy of extraordinary applause for the many new and true observations he has made."[69 70]

Sir Kenelm Digby writes—

"by means of whom (Gilbert) and of Doctor Harvey our nation may claim even in this latter age as deserved a crown for solid Philosophical learning."[71]

Coming down to modern times C. W. Cooke[72] tells us that "De Magnete" inaugurated a new epoch in physical science, its author announced discovery after discovery, all made by a series of experiments conducted in a most philosophical manner. He was the first electrician, he was the first to investigate electrical phenomena, and the word electric was coined by him. Sylvanus Thompson considers that Gilbert made 20 separate experimental discoveries in electricity alone.

It will not be amiss, before we leave "De Magnete," to glance at the short reference to medicine to be found in it. In Book I., Chapters XIV. and XV., Gilbert[73] ridicules the medical nonsense which has been talked about the loadstone, such as that, in small doses, it preserves youth, that smeared with garlic it ceases to be active, that when pulverised and then buried in plaster it will draw an arrow from the body, that it will cure all sorts of headaches. He sums up by saying: "Thus vainly and preposterously do the sciolists look for remedies when ignorant of the true causes of things." Chapter XV. treats of the medicinal virtue of iron. Gilbert is aware of its use in chlorosis, for "it restores young girls when pallid, sickly, and lacking colour, to health and beauty." Malaria was very common in England in his time; hence we find Gilbert advising iron for enlarged spleen; the patients improved, probably because the iron benefited their anæmia. He notices that it is astringent. These are its only medicinal virtues. This is an excellent account of the therapeutics of iron, we know but little more now. Gilbert is very sarcastic about the many ridiculous claims made for it by doctors. He says:

"Thus do the smatterers cross swords together, and puzzle inquiring minds by their vague conjectures, and wrangle for trifles as for goats' wool, when they philosophize wrongly."

In Book II., Chapter III., he points out that Galen errs in believing that whatever agents draw out the venom of serpents exhibit the same power as the loadstone; he is emphatic that drugs do not act in this way. These extracts show him to have been what was very rare in his day—namely, a scientific physician, believing no more than he sees, and scornfully disbelieving the rubbish that passed for medicine.

The "Advancement of Learning" appeared in 1605, two years after Gilbert's death, so it cannot have been of use to him, and the only one of Bacon's writings which can have been published before 1600, when "De Magnete" appeared, is "Partus Masculus Temporis" (The Male Birth of Time), but the date of this, which is only a fragment, is doubtful. There is no trace of any acquaintance between Gilbert and Bacon, therefore we must admit that there is nothing to show that the last can have affected the elder; consequently the glory of being the first in this country, at any rate, to break through the bonds of authorities and to properly use experiments and induction belongs to Gilbert. Considering his professional position, his sound medicine, his close acquaintance with Harvey's father-in-law, the fact that his arresting book appeared just when Harvey was beginning his medical work, that it was just such as would appeal to the discoverer of the circulation, for it, by example and precept, taught that th right way to investigate nature was by experimer and induction, and that Harvey's recreation wa mathematics; bearing in mind all this it is nc unreasonable to believe that Gilbert helped to dire Harvey's thoughts.

THE ATMOSPHERE IN WHICH GILBERT, BACON, AND HARVEY LIVED.

Hitherto we have only considered Bacon, Gilber and Harvey individually, but in what atmosphe did they live? Sir John Edwin Sandys tells us that—

"the love of discussing on learned and philosophic topi was one of the characteristics of serious society in t Elizabethan age."[74]

Sir Sydney Lee and Dr. Furnivall both say that th era of Elizabeth was that of learned culture and desire for knowledge among large numbers of th people.[75] Several accounts have been given of th Society of Antiquaries, founded in 1572. It was great success:

"Peers and commoners, diplomatists and exchequ officials, heralds and city tradesmen, country and tov gentlemen, schoolmasters, lawyers and clergymen, all m together, week by week, to discuss archeological and co stitutional problems."[76 77 78]

At the same time there was another learned socie which met at Gilbert's house on St. Peter's Hill. S Humphrey Gilbert, half brother to Sir Walter Raleg laid before Queen Elizabeth a scheme for the erecti of "An Achademy for educacion of her Maiest Wardes and others, the youth of nobility and gentl men." It was to have been a real University London; there were to be dozens of well-pa teachers, including one in natural philosophy, a there was to be one doctor of phisic. His duties I w give in the old spelling. One day he was to reed phisi and another surgery, in the English tongue. He w never to alleage any medicine of any kind but th he was to declare the reason philosophicil of eve particular and he was to show how the medicine w made and all the instruments used in making The physitian was to practise surgery because the were very few good surgeons, for surgery was only to learned in barbers' shops, which was most dangerou The physitian was continually to practise with t Natural Philsopher to try and search out the riddles nature, they were to share a garden for the growi of simples and for this they were to have an ext allowance.[79]

Learning was evidently much in men's thoug and in their conversation. Therefore on this grou also, we may reasonably conclude that Harvey wou have knowledge of the teaching of Gilbert and Baco

Many who have written about the gloric Elizabethan renaissance have told us of its lite ture, its theatres, its politics, its statesmen, voyagers and its romance, but few have dw upon its science. Until the closing years of t great Queen's reign ignorance, superstition, tra tion, and false reasoning darkened understandi but then, as with other branches of human activi so with science, great lights arose in this country Gilbert, Bacon, and Harvey—men's minds awo the science of electricity was founded, we were tau how to reason and modern physiology was bo English science dates from these three who w contemporaries; fortunately they were not, l Galileo, Bruno, Servetus, and others, persecuted account of the novelty of their pronouncements. T Elizabethan era is an example of the well-kno singular phenomenon that there are periods in wh a cluster of geniuses appears, and this College justly be proud that two of its Fellows may be grou with Shakespeare and a few others among the grea Elizabethans. Harvey's supreme eminence am scientists is so well acknowledged that there is need for me to extol it. Rather have I tried to show th not only was he a star of the first magnitude himself, he was also part of one of the brightest constellati the world has seen. No man can certainly say w

nakes any man's mind, but, for the reasons brought orward in this address, it does seem likely that, as Harvey was the youngest of these three, the other two ad some directing effect, of which Harvey was erhaps unaware, in steering his thoughts correctly owards that goal, the reaching of which has made him ne of the great men of all time.

All three were parched with a thirst for knowledge, nd it would be difficult to find a better epilogue to his oration than a quotation from the "Praise of Knowledge," a masque written by Bacon and erformed before Elizabeth in 1592:

"Therefore no doubt the sovereignty of man lieth hid in nowledge wherein many things are reserved which kings ith their treasure cannot buy, nor with their force ommand; their spies and intelligencers can give no news f them; their seamen and discoverers cannot sail where hey grow. Now we govern nature in opinions but are thrall o her in necessities. But if we would be led by her in nvention we should command her inaction."

Ingleby Lectures

ON

PLACE-IN-FAMILY AS A FACTOR IN DISEASE.

Delivered at the University of Birmingham

BY G. F. STILL, M.D. CAMB., LL.D. EDIN., F.R.C.P. LOND.,

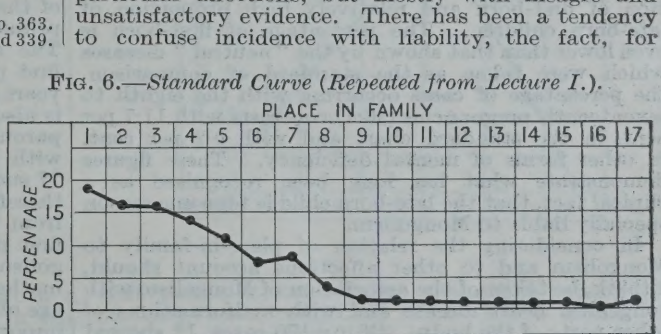
PROFESSOR OF DISEASES OF CHILDREN, KING'S COLLEGE HOSPITAL; CONSULTING PHYSICIAN, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

LECTURE II.*

IT will be well at the outset of this lecture, in which I propose to consider further the relationship of place-in-family to certain affections in children, that I should summarise the arguments and evidence with which the previous lecture was concerned.

That place-in-family may have some influence in determining liability to disease is not a new idea. Various writers have suggested it with regard to particular affections, but mostly with meagre and unsatisfactory evidence. There has been a tendency to confuse incidence with liability, the fact, for instance, that there is a much larger number of first-born than second-born in the statistics of any particular disease has been adduced as evidence of some special liability of the first-born regardless of the possibility that this predominance might be due to excess of first-born in the general population. It is only by comparing the place-in-family incidence of the particular affection with the place-in-family distribution of the general population that any conclusion can be formed as to any special liability attaching to place-in-family. Almost all the statistics which have been published on this point have omitted miscarriages and stillbirths from the order of pregnancies, so that what is recorded, say, as first-born may have been a third or fourth pregnancy or even later; a serious fallacy if, as seems at least possible, it is the occurrence or non-occurrence of previous pregnancies, whether they went to full term or not, which determines whatever influence place-in-family may have upon the offspring. The necessity of including miscarriages and stillbirths introduces a great difficulty in obtaining any reliable statistics of the general population to serve as a standard of comparison, for there is no official registration of miscarriages and until recently none of stillbirths.

FIG. 6.—*Standard Curve (Repeated from Lecture I.).*



The exact percentages indicated in Fig. 6 are: 18·5, 16·1, 15·4, 13·4, 10·8, 7·5, 7·6, 3·9, 2·1, 1·7, 1.6, 1·1, 0·7, 0·4, 0·1, 0·0, 0·1.

It was necessary, therefore, to obtain from some private source figures which were not subject to this fallacy, and I showed various charts which had been drawn up for this purpose, and gave reasons for selecting as the nearest approximation to accuracy statistics of certain diseases which might be regarded as "neutral" so far as my influence of place-in-family is concerned, and from these obtained a standard curve (Fig. 6). When, as a working hypothesis, a standard of comparison had been established,

* Lecture I. appeared in the last issue of THE LANCET.

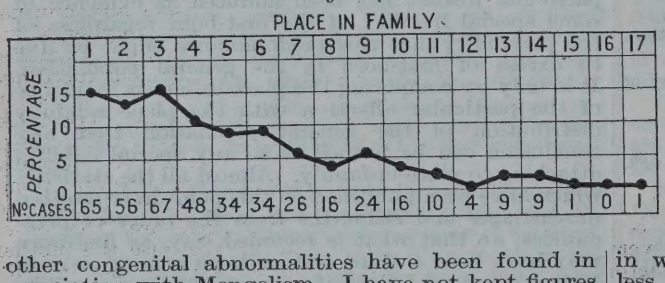
several affections of children were considered in turn, and it was shown by comparing the place-in-family incidence of certain affections with this standard that there is a special liability in the first pregnancy to abnormalities of development in the offspring. This was seen to be most striking in regard to congenital hypertrophy of the pylorus, but other congenital anomalies—viz., congenital heart disease, congenital malformations of various kinds, mental deficiency (exclusive of Mongolism), and probably epilepsy—were all found to show a similar relationship to the first pregnancy. A doubt arose with regard to the congenital spastic cerebral palsies because it is certain that some of these are due to intranatal causes rather than to antenatal, and my inquiry deals only with the influence of place-in-family in regard to conditions of antenatal origin.

MONGOLISM.

I pass on now to consider a particular form of mental deficiency with reference to place-in-family —namely, Mongolism. The chart in Fig. 14 comprises 420 cases (250 collected by Dr. J. Thomson, 170 by myself). It is seen to be in remarkable contrast with the curve shown by other forms of mental deficiency. Its special features are the comparatively low proportion of first-born and relatively high proportion of late-born children. The percentage of first-born is even lower than that shown by the "neutral" diseases which were taken as the standard of comparison, the percentage of cases occurring with the eighth to seventeenth pregnancies (20·4) contrasts with 11·7 per cent. in the standard chart and with 0·2 per cent. in other forms of mental deficiency. These figures demonstrate what has long been recognised as a clinical fact, that the late-born child is for some reason specially liable to Mongolism.

In considering the relation of place-in-family to Mongolism and to other affections account should, I think, be taken of the association of Mongolism with congenital heart disease and with malformations of other parts of the body. Of my 170 cases, 12 showed congenital heart disease—i.e., 7 per cent.—and other observers have found a much higher proportion, such as 15·7 per cent. (Thomson). A great variety of other congenital abnormalities have been found in association with Mongolism. I have not kept figures of the frequency of their occurrence, but in one series of observations (Thomson) it was 22 per cent. These associations make it probable that whatever may be the relationship between place-in-family and Mongolism the same holds good for the congenital heart disease or other abnormalities associated with Mongolism in these cases, and if the cause which underlies Mongolism can interfere with development so as to produce also these particular abnormalities, cardiac and otherwise, it seems likely that the same cause may also play some part in the production of developmental abnormalities apart from Mongolism.

FIG. 14.—*Mongols* (*420 Cases*).



This brings me to the significance of place-in-family, and first of all with regard to Mongolism. It is obvious that there are two factors which may be concerned in the special liability of the late-born to Mongolism—the number of pregnancies and the age of the mothers. Multiparity is certainly not essential to the production of Mongolism; amongst the 420 cases in Fig. 14 there were 65 cases belonging to the first pregnancy. But the large proportion of late pregnancies in comparison with that shown in the curves of other affections does at least justify the question whether the number of pregnancies has a greater influence than the age of the mother in determining the incidence of Mongolism on the late-born.

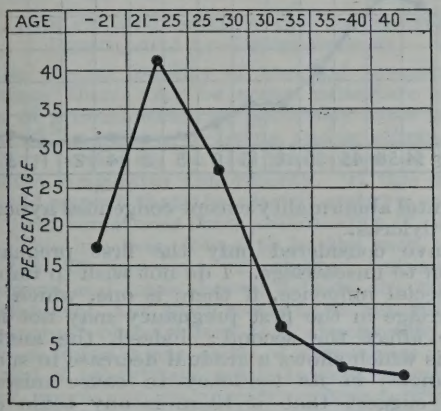
It is difficult to answer this by statistics, for obviously multiparity carries with it the probability of a more advanced age than is usual in the primipara. If it were found that when Mongolism occurred amongst the earlier pregnancies, such as the first or second, the age of the mother was usually higher than that of the average primipara or secundipara, this would point to the influence of age. I have notes of the age of the mother at the birth of a Mongol first-born in 26 cases; 19 of these were over the age of 30, including 11 of 35 years or older; the average was 33·3 years. As 56·5 per cent. of marriages (according to the Registrar-General's statistics for 1923) take place under the age of 25 years, and only 10·1 per cent. in women over 30 years of age, it is probable that the average age of the primiparous mother is considerably under 30 years; indeed, if the observations quoted by Matthews Duncan still hold good that the average interval between marriage and the birth of the first-born is about 12 months, the majority of primiparæ should be not more than 26 years old. The average age, therefore, of the mothers whose first pregnancy results in a Mongol is at least seven years above that of the majority of primiparæ. It is also about seven years above the age of the primiparous mother whose pregnancy results in a child with some other form of mental deficiency. In 77 such cases the average age was 26·2 years. So far therefore, as statistical evidence goes, it would seem from the comparative infrequency of Mongolism in first pregnancies, and from the fact that when Mongolism does occur in the child of a first pregnancy the mother is usually considerably beyond the average age of primiparæ, that the age of the mother is a more important factor in the production of Mongolism in the first-born than is the primiparity.

Again, if the special incidence of Mongolism upon the later children were due to the number of pregnancies which have preceded, rather than to the age of the mother, it might be expected that in the exceptional cases where a young woman less than 30 years of age produces a Mongol it would usually be found that she was a woman who had married early and had had at least three or four pregnancies before the Mongol. I have said "three or four pregnancies," but this is merely hazarding a guess at the number, if any, which might be thought to favour the occurrence of Mongolism. Actual figures taken without regard to the age of the mother (as in Fig. 14) prove that in 63·9 per cent. of the families in which Mongolism occurs there have been no less than three children before the Mongol, and in 52·5 per cent. not less than four children preceding the Mongol. This may be contrasted with some of the "neutral" diseases described in the previous lecture; for instance, in diarrhœa and digestive disorders, of 1000 cases 45·7 per cent. occurred in a child preceded by not less than three pregnancies and 32·8 in children preceded by no less than four pregnancies, and the corresponding figures in 400 cases of broncho-pneumonia were 49·7 per cent. and 37·45 per cent. A comparison of these figures justifies the expectation that if the number of antecedent pregnancies is an important factor in the causation of Mongolism, we should find that at least a considerable proportion of the mothers who gave birth to Mongols before they are more than 30 years old would have had three or four pregnancies before it.

I can only produce very small figures on this point because women under 30 years of age comparatively rarely produce Mongols. I have notes of 17 cases in which the mother of a Mongol was not more than

30 years old when the child was born; only three of these had had three children or more previously, eight of them were primiparæ, and five had had one previous pregnancy. So far, therefore, as this small number of cases is any criterion, it does not show that the number of antecedent pregnancies is particularly high in cases where the mother of a Mongol is exceptionally young, and it gives therefore no support to the view that the occurrence of Mongolism is due to the number of previous pregnancies. From these various considerations the conclusion seems to be justified that the influence of place-in-family in regard to Mongolism is only indirect; it is the age of the mother rather than the number of the particular pregnancy which determines the occurrence of Mongolism. This conclusion, it must be pointed out, throws no light upon the clinical fact that when a Mongol has occurred, whether early or late in the family, any subsequent children almost never show Mongolism.

FIG. 15.—*Age at Marriage in General Population.*



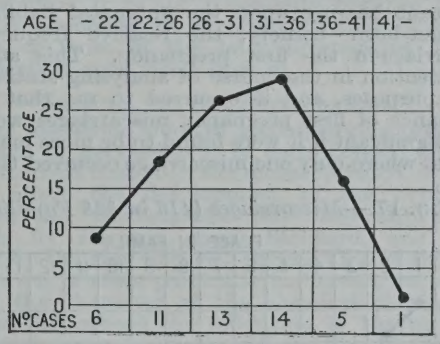
INFLUENCE OF THE MOTHER'S AGE.

In considering the occurrence of Mongolism in the first-born, I have shown that in that condition primogeniture was comparatively infrequent and that when it occurred it was probably of less importance in causation than the age of the primipara. How far is this true of other conditions? If the conclusions already reached are correct as to the special liability of the first-born to various congenital anomalies, is this because of the age of the mother or is it because primigravidity has some special influence per se, independent of the age of the mother? Primigravidity as a general rule implies comparative youthfulness of the mother, and the special incidence of any affection upon the first-born might, therefore, very naturally suggest that the chief, if not the only, factor in causation was the youthful age of the mother or as some writers have expressed it, her immaturity. If this is so the proportion of mothers of comparatively youthful age should be higher amongst those whose first pregnancy results in a child with some congenital malformation or abnormality than amongst the primiparæ of the general population.

In the Registrar-General's report for 1923 the age at marriage in the general population of England and Wales was: Up to 21 years, 15·3 per cent.; 21 to 25 years, 41·2 per cent.; 25 to 30 years, 27·9 per cent. (Fig. 15.) So that more than half the marriages occur under 25 years of age, and assuming Matthews Duncan's estimate to be correct that on the average the interval between marriage and the birth of the first-born is one year, one might suppose that at least 50 per cent. of primiparous labours would occur under the age of 26 years. There is some correction to be made for sterility, but to quote Matthews Duncan again, "those married at ages from 20–24 inclusive are almost all fertile," whilst of women married under 20 years of age about 7 per cent. are sterile. The correction to be made, therefore, is very small. In 50 cases of congenital deformities, including congenital heart disease, all occurring in first pregnancies, I have noted the age of the mother at the birth of the child and have reduced the numbers at the various ages to percentages which are shown in the chart (Fig. 16) so as to facilitate comparison with the average age at marriage.

It will be seen that so far from the proportion in the younger age-groups being higher than in the general population, it is decidedly lower, and the proportion in the later age-groups is actually higher than in the general population. So far, therefore, as these small figures are reliable there is no evidence that the special liability of the first-born to congenital abnormalities such as congenital heart disease, hare-lip, cleft palate, hydrocephalus, congenital hypertrophy of the pylorus, congenital deformities of limbs, &c., is due to the mother being below the average age of a primipara; or to put it in another way, there is no evidence that immaturity of the mother plays any part in the production of these abnormalities. Indeed, these figures rather suggest that an age above the average age for primigravidity is more favourable to these perversions of development than any unusual youthfulness of the mother. Moreover, in view of the frequent association of various congenital anomalies with Mongolism it seems probable that advanced age of the mother may be a factor also in the causation of congenital anomalies when they are not associated with Mongolism. If this is the case, and if, therefore, there are two factors in the production of congenital anomalies pulling, so to speak, in opposite directions, the one towards the first place-in-family because of the special influence of primogeniture, the other towards the late place-in-family because the mother is then reaching advanced age, the fact that in spite of these opposing tendencies there is such a remarkable predominance of first-born with congenital anomalies emphasises even further the influence of primogeniture.

FIG. 16.—*Maternal Age at Birth of Congenitally Deformed Child.*



INFLUENCE OF PRIMIGRAVIDITY.

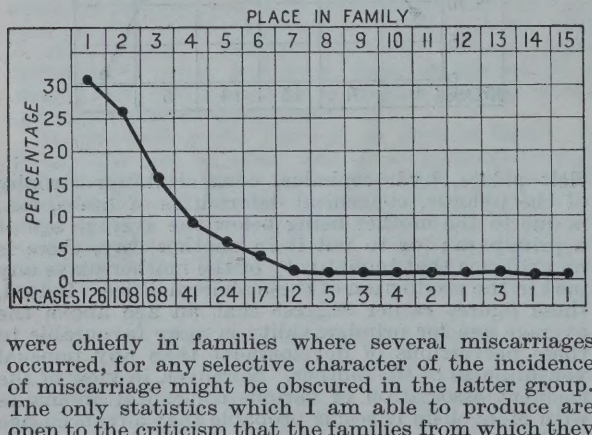
Is there any evidence then that independently of the age of the mother the first pregnancy is at a disadvantage? So far as the nutrition of the fœtus is concerned there is undoubtedly a tendency for the first pregnancy to fare badly. It is a common observation that the weight and length of the first-born are commonly less than those of subsequent children; various observers have published figures demonstrating this, notably Dr. Matthews Duncan (loc. cit.) who also discussed its relationship to primogeniture. He held that this relative deficiency in weight and length was directly dependent upon the age of the mother, whereas Hecker had regarded it as due to primogeniture per se. Subsequently, Hecker partly adopted Dr. Matthews Duncan's view, but with the reservation that age was not the only

factor—some influence must be exerted by primogeniture. It was recognised by these observers also that although on the whole there is much uniformity in the weights of the children of the subsequent pregnancies, there is in the later pregnancies a tendency to a decrease in the weight of the child, a fact which may not be without its significance in regard to the occurrence of anomalies of development in these later pregnancies. Comparative physiology gives some confirmatory evidence on these points; chicks from pullet's eggs are, on the whole, smaller than chicks from hen's eggs; a first litter of pigs is commonly smaller in number and smaller in size than later litters; with rabbits also a first litter is apt to consist of smaller rabbits than a later one. Again, one may compare with the production of Mongols in late pregnancies the production by hens of eggs containing no yolk when they make their last efforts at laying.

MISCARRIAGE IN THE FIRST PREGNANCY.

There is another fact which may have a still more important bearing upon the antenatal liabilities of the first-born—namely, the relative frequency of miscarriage in the first pregnancy. This attracted my attention in the course of analysing statistics for other purposes, and it occurred to me that a predominance of first pregnancy miscarriages would be more significant if it were found to be more marked in families where only one miscarriage occurred than if it

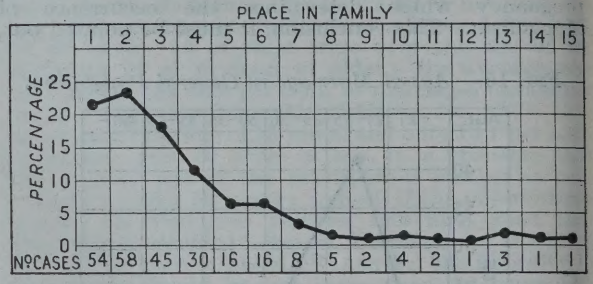
FIG. 17.—*Miscarriages (416 in 328 Families).*



were chiefly in families where several miscarriages occurred, for any selective character of the incidence of miscarriage might be obscured in the latter group. The only statistics which I am able to produce are open to the criticism that the families from which they were taken were not in all cases completed families. My impression is, however, that though statistics entirely free from this fallacy might alter the percentages to some extent, they would still show the same peculiarity in the incidence of miscarriage. It is seen that in 170 families when there was only one miscarriage this occurred in the first pregnancy in 42·3 per cent. of the cases, whereas in families in which there was more than one miscarriage the first pregnancy was affected in 22·1 per cent. of the cases. If there is no particular pregnancy which is more liable than any other to miscarriage, there seems to be no reason why the place-in-family incidence of miscarriage should not be identical with the place-in-family distribution of the general population, but if there is some special tendency to miscarriage in the first pregnancy, then the inclusion of the families in which only a first pregnancy miscarriage occurs will exaggerate the incidence on the first-born just as would the inclusion, say, of cases of congenital hypertrophy of the pylorus in a series of neutral diseases, especially if the pylorus cases were in the undue proportion which occurs, for instance, in the case notes of a children's physician.

A comparison of the three charts given here seems to bear out the view that for some reason there is a special liability of the first pregnancy to miscarriage; the chart (Fig. 17), including all miscarriages, shows 30·4 per cent. in the first pregnan cy,a figure considerably above the proportion of first pregnancies in the general population, in those statistics which, as I showed in my first lecture, could fairly be taken as a standard. If the families are excluded in which there is only one miscarriage the proportion of miscarriages is then 22·1 per cent. (Fig. 18) in the first pregnancy, which approximates to the proportion of first pregnancies in the standard curve of the general population, 18·5 per cent., whilst the chart of the families in which there is only one miscarriage (Fig. 19) shows an incidence on the first pregnancy of 42·3 per cent., a proportion higher than that shown by any

FIG. 18.—*More than One Miscarriage (246 in 85 Families).*

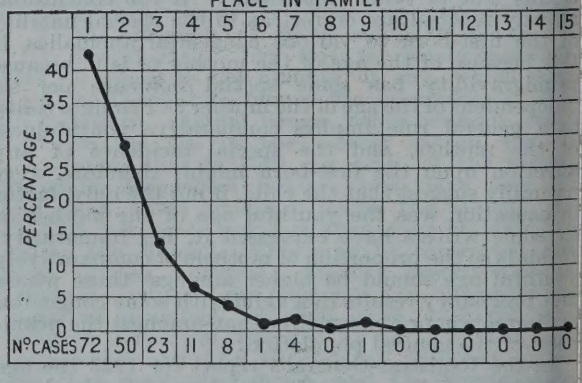


congenital abnormality except congenital hypertrophy of the pylorus.

I have considered only the first pregnancy in relation to miscarriage. I do not wish to imply that the special influence, if there is one, which favours miscarriage in the first pregnancy may not in some degree affect the second; indeed, the analogy of syphilis which shows a gradual decrease in successive pregnancies in its tendency to cause miscarriage, would suggest that if there is any toxic element specially favouring the occurrence of miscarriage in the first-born this might extend in some degree beyond the first pregnancy. Here, however, I am concerned with the first chiefly, and the figures already given furnish at least ground for supposing that there is in the first pregnancy some influence at work in the mother which makes this particular pregnancy specially liable to miscarriage.

It is more than possible that such an influence might in some cases result not in miscarriage but in

FIG. 19.—*Single Miscarriages (170).*



the death of the fœtus so that it would be stillborn. This possibility would be analogous to the effect of parental syphilis, which, as is well known, often produces at first one or more miscarriages and then a stillbirth premature or at full time before a living child is born. Stillbirths, therefore, may be another manifestation of the special influence, whatever it may be, which favours the occurrence of miscarriage in the first pregnancy. It is not suggested that stillbirth in the first pregnancy is usually the result of any such cause, it is certainly not! The mechanical difficulties of a first labour are undoubtedly the most frequent cause of the stillbirth; nevertheless, there

are cases in which there is no such mechanical cause, and, indeed, death of the fœtus has occurred before labour began. I have no figures to show whether this death of the fœtus before labour is relatively commoner in the first pregnancy than in later pregnancies, but stillbirths are certainly much commoner in the first than in the later pregnancies. In the 328 families already mentioned there were 74 stillbirths, and of these 36—i.e., close on 50 per cent.—were in the first pregnancy. I do not suggest that miscarriage is always a morbid process, but it certainly is in some; I have already instanced the effect of syphilis. On the other hand, it does not seem likely that miscarriage, when occurring apart from obvious disease, is a merely fortuitous occurrence. No doubt there are many miscarriages which are due to purely accidental causes, physical or psychical, but there remains a considerable proportion which cannot be explained in this way.

Relation of Miscarriage and Stillbirth to Perversion of Development.

In the special liability of the first pregnancy to miscarriage there may be some indication of perversion of process which in particular cases leads to ejection of the embryo or fœtus, and in others, where pregnancy continues, to the production of a child with some congenital abnormality. If this were so one would expect that the ejected embryo or fœtus would itself sometimes show abnormality of development. This has been found to be the case. Mall[1] found that 38 per cent. of aborted fœtuses were pathological and some showed definite abnormalities of development, and there seems to be general agreement amongst obstetricians that abnormality in the embryo or fœtus is one cause of miscarriage; if this is so, and if miscarriage tends to occur specially in the first pregnancy, we may have here further confirmation of the special tendency to abnormalities of development in the first pregnancy.

I know of no observations on the frequency of abnormal embryos or fœtuses in relation to place-in-family of the pregnancy. Routine investigation of the products of miscarriage and stillbirth from this point of view might give valuable information. It is a pity that these are often treated as negligible items in the reproductive history of a woman; it is possible that they might furnish some useful clue to the problem of developmental abnormality. If, as the figures already shown suggest, there is a special liability to miscarriage in the first pregnancy, how far is this predominance due to special frequency of abnormalities in the embryo or fœtus, and how far are both the result of some perversion of reproductive metabolism to which primigravidæ are specially liable? Unfortunately, upon this point, which may be nearer to the root of the whole problem of congenital abnormalities than we know, I can throw no light.

It is true that the impregnated ovum meets with conditions in the uterus of the primigravida which are peculiar to the first pregnancy; it finds a uterus in which there is as yet no enlargement or thickening of the arteries for the increased requirements of blood-supply, no modification of the venous channels by the involution processes of former pregnancies; all these have yet to be acquired; the environment is special, and at first sight one might imagine that the peculiarity of the first pregnancy in these respects might influence not only the continuation of the pregnancy but also the development of the embryo and fœtus. But even if it be granted that differences in the conditions of blood-supply may affect the nutrition of the embryo and fœtus, this is not necessarily any explanation of perversion of development. There is reason for thinking that the causes of developmental abnormalities lie deeper than mere difference of blood-supply.

The selective character of congenital abnormalities in some cases and their hereditary character in others seem to argue some altogether subtler and more profound influence. By "selective" I mean the tendency to fix upon particular structures in particular families; for instance, I have notes of one family in which there were only two pregnancies and both had congenital hydrocephalus; in another family there were two children with syndactyly, in another two with congenital heart disease, and in another I saw a boy who was said to be one of three who had congenital heart disease out of a family of 13; more striking examples are on record of six and seven children with congenital hydrocephalus, and in one instance six successive premature infants, and then three full time, all nine having congenital hydrocephalus (Göhlis). In most of the examples I have quoted—and, as I mentioned in my previous lecture, the occurrences of congenital deformities in more than one member of a family is uncommon—the malformation occurred in the first pregnancy and was repeated in subsequent pregnancies, so that whatever the influence may be which determines the special liability of the first pregnancy, to such abnormalities, it is not necessarily confined to the first; it is sometimes so profound that it extends to one or more of the later pregnancies, though fortunately it very rarely does so.

Toxæmia in the Primigravida.

If the metabolic changes accompanying pregnancy are liable to perversion it is quite conceivable that some chemical change in the mother's blood or tissues might affect the development of the ovum and embryo, and the experimental observations upon animals by Hertwig, Loeb, Stockard, and others quoted by Dr. Mall (loc. cit.) suggest that such a cause might even produce particular malformations according to the character of the chemical change. On such an hypothesis the repetition of the particular congenital anomaly in several children of the same mother would be intelligible. This view might also throw some light on the special liabilities of the first pregnancy, for it is known that there is a special tendency to the grosser toxæmic states in the primigravida. Recent figures taken on a large scale by independent observers[2] have shown that 74 per cent. of the cases of toxæmia in pregnancy occur in primigravidæ. This incidence, like the special tendency to abnormalities of development in the first pregnancy which I have shown not to be dependent upon any special youthfulness of the mother, is not dependent upon her age; "primigravidæ," says Dr. G. FitzGibbon,[3] are more liable to toxæmia than multiparæ, but the age of the primigravida has no influence on its development." This high percentage, 74 per cent., compared with the standard proportion of first pregnancies, proves, I think, that so far as the grosser forms of toxæmia which produce unequivocal symptoms in the pregnant woman are concerned, there is a marked special liability of the primigravida. If this is so it seems at least possible that the primigravida may also be specially liable to toxic states of less pronounced degree which, without producing obvious effects in the woman, may adversely affect the ovum or embryo. I would suggest that in some such special tendency of primigravidæ to a toxic state we may have an explanation in part at least of the special liability to congenital abnormalities in the offspring of the first pregnancy.

I have said "in part," for it is evident that even so far as the first pregnancy is concerned, place-in-family is not the only cause of congenital anomalies; advanced age of the mother is sometimes a factor, as shown in cases where Mongolism occurs in a first-born and probably in some cases where other congenital anomalies occur in the first-born of an elderly mother, for as I have shown the association of such anomalies with Mongolism in a late-born child seems to indicate that the age of the mother can be responsible for them also.

But surely there are other factors concerned in the problem of place-in-family even less capable of demon-

[1] F. P. Mall in Keibel's Manual of Human Embryology, p. 207.

[2] Jour. of Obstetrics and Gynæcology of Brit. Empire, 1923, xxix., 390.

[3] Ibid., p. 404.

stration than those I have considered. Is it likely that the reproductive process is exempt from those irregularities which characterise other functions of the body at their inception and at their decline? Imperfect function at first, failing function at last, this is so well ascertained an order of physiological events in respect of other processes that it may well apply also to the reproductive process and so be to some extent at once an explanation and a confirmation of the relation between place-in-family and developmental anomalies. Certainly Nature's first experiment at reproduction is more often a failure than her later ones; and when the reproductive period is nearing its close, Nature is again prone to failure, and if miscarriage and developmental anomalies are so closely connected as I have suggested, it may be that the special liability to miscarriage in the first pregnancy is more often a boon than we know: Nature thereby may be throwing aside the imperfect result of her first effort.

INTERVAL BETWEEN PREGNANCIES.

I pass now to another point which I think merits more attention than it has received. I know of no published reference to it, though I know from conversation with colleagues that it has not been unnoticed. I refer to the occurrence of some congenital abnormality in the child born at an unusually long interval after the preceding pregnancy. What may be the interval which encourages this risk I am not prepared to say. I have noted particularly cases with six years or longer interval; possibly the risk, if it exists, may be proportionate to the length of the interval; certainly in many of them it is eight or ten years or even longer. The occurrence of a long interval before the abnormal child is particularly noticeable in Mongolism. I have notes of several cases with 10, 11, and 12 years interval between the previous pregnancy and the Mongol, and of others with five, six, or seven years interval. This is by no means limited to Mongolism. I have noted it, though less frequently, in other forms of mental deficiency, and in various congenital abnormalities and deformities. Many of my records were taken before this point had attracted my attention so I am unable to offer any opinion as to its frequency, and it is essential that the frequency of its association with abnormality of the offspring should be compared with the frequency of similar intervals where the offspring are not abnormal, before any conclusion can be drawn as to a causal relation.

In the absence of sufficient statistics to have any evidential value, I can only draw attention to the possibility that pregnancy separated by an unusually long interval from the preceding pregnancy involves some special risk of abnormality in the offspring. If this is so its explanation must be intimately related to the whole problem of the causation of congenital abnormalities. It might be argued that the age of the mother is advanced to the extent of the interval and that it was because of advanced age and not because of any other influence of the interval that the abnormal offspring resulted. I have notes of cases in which the long interval occurred quite early in the reproductive history of the mother, so that in these at any rate the abnormality of the child could hardly be due to the age of the mother. Possibly the interpretation of this occurrence may be that the longer the interval the closer the return to the conditions of primigravidity, so far as those special influences are concerned which render the primigravida specially liable to have abnormal offspring.

In conclusion, let me say that in these lectures I have tried to accumulate facts which might help towards an understanding of one, at any rate, of the antenatal factors entering into the production of congenital abnormalities—namely, the influence of place-in-family; but I realise that this is only one factor, perhaps only a predisposing factor; the fundamental causes lie deeper. At present we can only feel our way towards them groping in the half-light towards the truth.

A CLINICAL STUDY OF THE ALKALI TREATMENT OF SCARLET FEVER.

BY E. H. J. BERRY, M.B., M.R.C.P. LOND.

DURING the treatment of nephritis of all types A. Osman [1] noticed that when an acid urine was made alkaline the amount of albumin passed was lessened and the amount of urine passed was increased, with a corresponding improvement in the patient's general condition. While working along these lines, he encountered a case of anuria caused apparently by a large doses of sanocrysin. The anuria was overcome after large doses of alkalis, and the patient recovered. To determine whether this principle of rendering the urine alkaline was effective in nephrites other than those caused by metallic poisons, he determined to try the treatment in scarlet fever, of which abundant material would be available. A short résumé of his results was given in an address to the Royal Society of Medicine, in which he stated that the incidence of cases of albuminuria and nephritis had fallen from 5·5 per cent. to 0·6 per cent.[1] These figures are so remarkable that they demand further investigation; there can be no doubt that a new and valuable principle in treatment has been discovered.

In the past, alkalis have been given empirically as diaphoretics for febrile disturbances such as occur in the exanthemata. They were thought to be "cooling" medicines, and there was no clear conception as to how they acted and why they undoubtedly did good. Now that the urine is being tested for acidity and alkalinity, it seems that in most cases these drugs were not being given in sufficient quantities, and that because their manner of action and effects on the urine were unknown, their administration was not properly controlled.

Before the introduction of salicylates, rheumatic fever was treated by large doses of alkalis, and even now, as Osler states, improvement in the condition of the patient takes place as soon as the urine becomes alkaline.

That alkalis tend to prevent the onset of nephritis in scarlet fever has been proved beyond doubt, but that the alkali treatment is also of value in the prevention of other complications and as a curative measure has apparently escaped notice. If alkalis prevent the onset of one toxic manifestation, and the various complications of scarlet fever are due to one particular scarlatinal toxin acting on tissues of varying resistance, it is reasonable to suppose that they would prevent the onset of other manifestations possibly toxic in origin, such as, for example, scarlatinal rheumatism.

From the following figures I wish to show that albuminuria and rheumatism are closely related, and that, in preventing the onset of one, we can prevent the onset of the other.

Reliable figures of the crippling effects of rheumatic fever on the heart were given by Cheadle in 1889. He stated that 72 per cent. of children suffering from rheumatic fever showed cardiac lesions. Sir Thomas Horder, in 1926, quoted the conclusions which Church made over 40 years ago. These are practically the same as those quoted by Cheadle, but Church adds that cardiac and lung complications were at that time diminishing. Cardiac complications do not occur so frequently in scarlatinal rheumatism, but they are present to the extent of 17·3 per cent. If it can be proved that the alkali treatment can prevent or lessen the incidence of scarlatinal rheumatism, then the beneficial effect of the alkali treatment is indeed very great.

The treatment of scarlet fever, until the recent introduction of anti-scarlatinal serum, was entirely symptomatic and empirical. I have not been able

[1] Proc. Roy. Soc. Med., 1927, xx., 1405; see THE LANCET, 1927, i., 971 and 1107.

o try American anti-scarlatinal serum, but have ısed British serum. The results, in my hands, have ıot corresponded with those of Gardner Robb,[2] ınd, on the whole, have been unsatisfactory. The lkali treatment has given much better results.

For this article a study has been made of all the ases of scarlet fever which were admitted to Joyce reen Hospital in 1926. There is a convention in his hospital of calling those cases where albumin lone appeared in the urine, cases of albuminuria, nd those cases in which the urine contained blood nd albumin, cases of nephritis. To my mind the ifference is only one of degree. Nephritis may rst manifest itself by the appearance of blood and lbumin in the urine; in other cases the urine will rst contain albumin and later blood. Others, gain, may have intermittent albuminuria and lood in the urine later. These manifestations may ccur at any time of the disease, from admission to ıe sixth week, but the majority of cases occur in ıe third week. Therefore, to divide cases into buminuria and nephritis seems to serve no useful inical purpose. All cases of albuminuria are actually potentially cases of nephritis. No laboratory ethod of estimating the urinary pH was employed; ıe alkalinity or acidity of the urine was determined litmus paper. The urine tested was that first ıssed in the morning, before breakfast.

In 1926, 2819 cases of scarlet fever were admitted Joyce Green Hospital. No attempt has been made separate cases of febrile albuminuria from cases toxic albuminuria. Excluding those which veloped another infectious disease before the pearance of albuminuria, there were 303 cases of buminuria and nephritis—i.e., 10·6 per cent. xty-nine cases developed rheumatism—i.e., 2·5 per nt. Of these, 19 had albuminuria. Thus the rcentage of rheumatic cases having albuminuria ıs 27·5. These figures show the close relationship tween albuminuria and rheumatism.

The total number of cases showing cardiac com-cations was 46—i.e., 1·5 per cent. The number albuminuric cases showing cardiac complications, d in whom no rheumatism was present, was 4—, 1·3 per cent. Thus, albuminuria does not appear increase cardiac complications. The total number rheumatic cases showing cardiac complications vs 12—i.e., 17·3 per cent. Thus there is a direct ationship between rheumatism and endocarditis.

A review of the first 100 cases treated by alkalis es some very interesting information. The patients ated were not selected cases. Their ages varied m $1^{11}/_{12}$ years to 25 years. The object was to make urine alkaline as quickly as possible and to keep alkaline for three weeks, during which time the ient was kept in bed. Of these 100 cases, one veloped albuminuria and rheumatism, and one veloped albuminuria while on alkalis. The mixture en contained gr. 40 of pot. cit. and gr. 40 pot. arb. to the ounce of water.

ASE 1.—A young soldier, aged 15, admitted April 8th, 7, with a severe attack of scarlet fever. His urine was le alkaline on the second day, and remained so for three s on half ounce of the mixture. On the sixth morning it tained a faint trace of albumin; reaction still alkaline. dose of alkalis was doubled, but next morning the urine acid and he complained of joint pains. The mixture increased to 1½ ounces. Next morning the urine aline and remained so on the same dose till the patient discharged. Albumin was present in the urine for days; there were no casts. The urinary diastase was mal and the blood urea was also normal. He had, admission, a faint systolic apical bruit, but with the earance of rheumatism it became more pronounced. re were signs of early phthisis at the right apex. He since been invalided out of the army.

ASE 2.—A child, aged 5, was admitted on Dec. 31st, . She was given 2 drachms of the mixture, but the e remained acid on this dose, and on Jan. 3rd the urine ained a trace of albumin. Six drachms of the mixture given. The urine became alkaline and albumin-free an. 7th. She later developed left otorrhœa but no other plication.

Three cases who were given the mixture for three weeks developed albuminuria after the alkalis had been stopped. One developed rheumatism 20 days after the mixture had been stopped, and albuminuria next day. Alkalis were again given and the urine became albumin-free in four days. Another had, for three days, a faint trace of albumin six days after the mixture had been stopped. The last case developed albuminuria the day his urine became acid. He was transferred from my care and was not given alkalis, but he was discharged well.

It seems obvious that alkalis should be given all the time the patient is considered infectious, especially as nephritis may develop late in the disease. Had the urine of all patients been kept alkaline during their stay in hospital, it is possible that albuminuria would not have developed in three cases. Five per cent. of these cases developed albuminuria, two while on alkalis and three after the alkali course of three weeks had ended. Two per cent. had rheumatism, one while on alkalis, the other after the alkali course was finished.

In Case 1 it is worth noting that when albumin appeared the dose of alkalis was doubled, but in spite of this the urine next day was acid—i.e., the condition of acidosis had increased considerably with the onset of albuminuria.

I have seen the same thing occur in several cases of scarlatinal nephritis. When nephritis developed the urine was made alkaline on a certain dose of alkali; suddenly the urine would become acid and the patient develop joint pains. The dose of alkalis had to be increased considerably before the urine again became alkaline. There would seem to have been a sudden rise in the toxins of the blood, sufficient to cause an acidosis, and a degeneration of some part of the renal tissue.

The curative value of alkalis is most marked in toxic cases. It is not uncommon to see a child with a badly-developed rash, semi-comatose, semi-delirious, with a dry, peeled, cracked tongue. The urine of these patients always contains acid radicles when tested by the ferric chloride test, even when the child has had plenty of carbohydrate. If such a case be treated energetically with alkalis the change in 24–36 hours is very marked. The urine no longer gives a ferric chloride reaction; the tongue becomes moist; the rash becomes vivid; delirium disappears, and the child sits up in bed and takes an interest in the happenings of the ward. The temperature falls by crisis. If the child cannot swallow, the alkalis must be given by the rectum. The quantity of alkalis required to make the urine of a toxic case alkaline is surprising. One child, aged 5, required gr. 640 in 24 hours. I have not seen such a marked change as that portrayed above follow the use of serum.

So convinced am I of the beneficial effects of alkalis in toxic cases of scarlet fever, that I consider all toxæmic cases, from whatever cause, should be treated in a similar manner.

Conclusions.

(1) It has been proved that alkalis very considerably lower the incidence of nephritis. (2) Scarlatinal rheumatism and albuminuria are related to the extent of 27·5 per cent. (3) Scarlatinal rheumatism and endocarditis are related to the extent of 17·3 per cent. (4) Since albuminuria and rheumatism are so strongly related, and the incidence of nephritis can be lowered by alkalis, then it is reasonable to suppose that the incidence of scarlatinal rheumatism can also be appreciably lowered by the alkali treatment. (5) If the incidence of scarlatinal rheumatism can be appreciably diminished, it follows that the incidence of cardiac complications can be lessened. (6) In the acute stages of scarlet fever, if alkalis be given in sufficient doses to render the urine alkaline, great improvement in the patient's general condition results.

I am indebted to Dr. A. F. Cameron, medical superintendent of Joyce Green Hospital, for his kind permission to carry out this work in his hospital, and to the sisters for their willing coöperation.

THE TREATMENT OF THE PARKINSONIAN SYNDROME, FOLLOWING ENCEPHALITIS, BY MALARIA.

BY ROY N. CRAIG, M.D. DURH., D.P.M. LOND., B.S.,
PHYSICIAN-IN-CHARGE OF NERVOUS DISEASES, TORBAY HOSPITAL, TORQUAY, AND THE DISPENSARY, EXETER.

TREATMENT of the after-effects of encephalitis has, so far, proved unsatisfactory. Owing to the considerable degree of improvement which may follow malarial infection in general paralysis of the insane, it was felt justifiable to ascertain the results in encephalitis. Belladonna, hyoscine, parathyroid, and iodides undoubtedly tend to make the patient infinitely more comfortable—more particularly, perhaps, in reducing the constant flow of saliva which is such an unpleasant and constant feature of the Parkinsonian state. They are, however, purely palliative and do not in any way arrest the progress of the disease.

It is possible that the after-effects of encephalitis, such as the Parkinsonian state, are due to damage of the basal nuclei and great correlating centres in the mid-brain during the acute phase of the disease. If this is so, no improvement could be hoped for by treatment, as the damage has already been done. On the other hand, there is a feeling that the Parkinsonian state may be due to a gradual invasion or extension of the disease into the mid-brain, and that the disease is still active. The involvement, in some cases, of the anterior horn cells and perivascular cuffing with lymphocytes rather suggest that the disease is still active. Though the Parkinsonian syndrome may predominate, certain of these cases have such a complex syndrome that it is almost impossible for the lesions to be entirely confined to the mid-brain alone.

It was on the supposition that the disease might be still active that this treatment was undertaken, in the hope that further extension might be arrested and that, if the axon itself had not actually been destroyed, some improvement might take place.

Eight cases have been treated by this method. They were selected from the neurological out-patients in Exeter, the Torbay Hospital, and from private practice. All of these cases had an attack of encephalitis within the last three years, except one case which had the acute attack eight years previously. All had the Parkinsonian syndrome, to a greater or lesser degree, with bradykinesia, tremors of the hands, rigidity of the trunk, excessive salivation, and slow cerebration. There was a varying degree of mental involvement, which is outlined in each individual case. All had diplopia at the time of the acute onset.

Technique.

The technique used was as follows. All the cases were inoculated directly by anopheles mosquitoes infected with a known strain of benign tertian malaria. The mosquito was allowed to inoculate the patient on the thigh through small meshed gauze over a glass beaker in which it was contained. The period of infection varied very considerably—from the twelfth to the twenty-second day after infection. Once this had taken place the temperature mounted with each successive rigor from 99° F. on the first, 100° on the second, 101° on the third, to 105° on the fourth day. The blood was controlled at varying intervals to check the progress of the malaria in order that any very considerable excess of parasites might be foreseen. The temperature was taken every quarter of an hour, during a rigor, until the highest point had been reached and the temperature began to fall. This, though tedious, is an extremely important part of the technique, in that the temperature may mount so rapidly that, if taken at longer intervals, the maximum rise can well be missed by several degrees. Tepid sponging was used whenever the temperature reached 105°. Nine rigors of 105° were aimed at and the infection was not stopped until this had been reached unless an excess of parasites in the blood film indicated an impending crisis or the patient's condition did not justify further treatment. At the end of the ninth rigor 5 g. of quinine were given three times a day for five days, and 10 g. for the next 12 days. This effectually checked the malaria, and no recurrence has followed.

All the cases treated stood their rigors well, and though a considerable degree of prostration was present on the day of the rigor, there was a rapid recovery on the following day, which enabled the patient to take ample supplies of nourishment and to fortify himself for the next rise of temperature.

Case Histories.

CASE 1.—H. P., aged 34.

History.—Encephalitis in 1919. Three years later he noticed that he was losing power in both hands and legs and that he was developing tremors in his hands.

Condition Prior to Treatment.—Marked loss of facial expression. Spasticity and exaggerated reflexes in both arms and legs. Skin shiny and moist. Constantly salivating. Mentally dull, apathetic, and depressed. No central nervous involvement. No nystagmus. Cerebro-spinal fluid: No excess of protein. Blood: Rouleau and fibrin formation normal. Hæmoglobin, 80 per cent.; red blood corpuscles, 4,762,400; colour-index, 0·8; white blood corpuscles, 6031; polymorphonuclears, 56 per cent.; small lymphocytes, 24·5 per cent.; large lymphocytes, 2·0 per cent.; eosinophils, 0·0 per cent.; basophils, 1·0 per cent.; large hyalines, 0·5 per cent. No changes were seen in the stained red cells. Blood-sugar curve within normal limits.

Present condition (six months after treatment).—Facial expression at rest; still shows some mask-like tendency, but can now smile or frown quite easily. Both arms and legs still some degree of spasticity, but considerably less than before. Skin much drier with no sweat. No excess of saliva. Mentally much improved; is bright and cheerful.

CASE 2.—M. C., aged 31.

History.—Acute attack of encephalitis two years ago. She made an apparent complete recovery from this attack. Two years later she found that she was beginning to lose power in both hands and that she was developing tremors in them. Her mouth constantly secreted saliva and she had very great difficulty in swallowing.

Condition Prior to Treatment.—Well-marked Parkinsonian syndrome with mask-like face, inability to express any emotion, spasticity and exaggerated reflexes in all limbs, shiny skin, and unpleasant-smelling sweat. Cerebro-spinal fluid: No excess of protein. Blood: Rouleau and fibrin formation normal. Hæmoglobin, 80 per cent.; red blood corpuscles, 4,350,000; colour-index, 0·9; white blood corpuscles, 6500; polymorphonuclears, 65 per cent.; small lymphocytes, 22 per cent.; large lymphocytes, 2·5 per cent.; eosinophils, 0·0 per cent.; basophils, 1·0 per cent.; large hyalines, 0·45 per cent. No changes were seen in the stained red cells. Blood-sugar curve within normal limits.

Present Condition (six months after treatment).—In general appearance is considerably improved in that the skin is no longer shiny and there is no strong-smelling sweat. She is able to swallow better and there is less spasticity. In spite of this apparent improvement she herself still feels ill, and a mental condition almost amounting to a degree of anxiety neurosis is still left. She is tending to relapse, and her mental condition is the most serious of all the cases treated.

CASE 3.—C. W., aged 18.

History.—An acute attack of encephalitis two years ago. He made an apparent recovery, but 18 months later noticed that he was losing power in both arms and legs, that his mouth was constantly full of saliva, and that he had considerable difficulty in swallowing.

Condition Prior to Treatment.—General rigidity of trunk. Marked bradykinesia. Excessive salivation. All reflexes exaggerated. Tremors of hands and legs. Cerebration slow. Was rapidly going downhill. Cerebro-spinal fluid: No excess of protein. Blood: Rouleau and fibrin formation normal. Hæmoglobin, 78 per cent.; red blood corpuscles, 4,600,000; colour-index, 0·8; white blood corpuscles, 6900; polymorphonuclears, 54 per cent.; small lymphocytes, 24 per cent.; large lymphocytes, 3·0 per cent.; eosinophils, 0·0 per cent.; basophils, 1·0 per cent.; large hyalines, 0·5 per cent. No changes were seen in the stained red cells. Blood-sugar curve: 0·11, 0·15, 0·195, 0·175, 0·15.

Present Condition (six months after treatment).—Up to three months ago there was an apparent improvement, but he has now started to relapse again. He is experiencing great difficulty in swallowing and has a return of the salivation and tremors.

CASE 4.—D. W., aged 31.

History.—Acute encephalitis two years previously, from which an apparent recovery was made. Eighteen months later she began to lose power in arms and legs and developed typical Parkinsonian syndrome with a constant flow of saliva.

Condition Before Treatment.—Rigidity of trunk. Exophthalmos. Tremors (pin-rolling type) in both hands. Exaggerated reflexes. Skin shiny, covered with sour-smelling sweat. Mentally dull and apathetic; cerebration slow. Cerebro-spinal fluid: No excess of protein. Blood: Rouleau and fibrin formation normal. Hæmoglobin, 72 per cent.; red blood corpuscles, 4,300,000; colour-index, 0·8; white blood corpuscles, 7000; polymorphonuclears, 72 per cent.; small lymphocytes, 23 per cent.; large lymphocytes, 3·0 per cent.; eosinophils, 0·0 per cent.; basophils, 1·0 per cent.; large hyalines, 0·4 per cent. No changes were seen in the stained red cells. Blood-sugar curve: 0·105, 0·155, 0·17, 0·175, 0·15.

Present Condition (three months after treatment).—Saliva within normal limits. Exophthalmos reduced. No excessive sweating. Mentally brighter and cerebration not so slow. Tremors and rigidity remain unaltered.

CASE 5.—B. N., aged 10.

History.—Acute encephalitis two and a half years previously with marked inversion of sleep-rhythm. The latter gradually cleared up and merged into the Parkinsonian state with all the usual features.

Condition Prior to Treatment.—Slight rigidity of trunk and festination. Exaggerated reflexes. Tremors of hands and feet. Excess of saliva. Excess of sweat. Only just able to smile. Mentally dull and depressed; cerebration very slow. Cerebro-spinal fluid: No excess of protein. Blood: Rouleau and fibrin formation normal. Hæmoglobin, 76 per cent.; red blood corpuscles, 4,200,000; Colour-index, 0·9; white blood corpuscles, 5400; polymorphonuclears, 74 per cent.; small lymphocytes, 21·5 per cent.; large lymphocytes, 0 per cent.; eosinophils, 0·0 per cent.; basophils, 0 per cent.; large hyalines, 0·5 per cent. No changes were seen in the stained red cells. Blood-sugar curve within normal limits.

Present Condition (four months after treatment).—Saliva and sweating reduced. Considerable improvement in facial expression. Mentally brighter. Some degree of rigidity of trunk still present. Tremors present and reflexes still exaggerated.

CASE 6.—V. R., aged 16.

History.—Acute encephalitis two years ago, from which apparent recovery was made. A year and nine months later she noticed that her mouth was constantly full of saliva. This was followed by weakness of the arms and legs, a general bowing of the trunk, and difficulty in swallowing.

Condition Prior to Treatment.—Well-marked Parkinsonian picture with exaggerated reflexes, tremors, rigidity, and cyanosis of extremities. Constant flow of saliva. Immobility of expression. Unable to feed herself. Mentally dull and depressed; cerebration very slow. Cerebro-spinal fluid: No excess of protein. Blood: Rouleau and fibrin formation normal. Hæmoglobin, 82 per cent.; red blood corpuscles, 5,000,000. Colour-index, 0·75; white blood corpuscles, 9,300; polymorphonuclears, 68 per cent.; small lymphocytes, 21 per cent.; large lymphocytes, 3 per cent.; eosinophils, 0·0 per cent.; basophils, 1·5 per cent.; large hyalines, 0·5 per cent. No changes were seen in the stained red cells. Blood-sugar curve within normal limits.

Present Condition (six months after treatment).—Facial expression improved and less difficulty in swallowing. A reduction of salivation. She can now feed herself and mentally is much brighter. There are still present, however, tremors, exaggerated reflexes, and bowing of the trunk.

Conclusions.

(1) Some temporary degree of improvement is apparent in all the cases. (2) The improvement is most apparent in the decrease of salivation and sweating, quicker cerebration, and in the facial expression. (3) There is apparently some degree of improvement in the mental condition; though, all the above cases having been told that their condition was incurable, discount has to be made to a certain extent for the improvement brought about by the patient feeling that something further is being done. (4) Little or no improvement is apparent in the rigidity of the trunk, exaggerated reflexes, and tremor. (5) The actual length of time that has ensued since the onset of the disease does not, however long, necessarily indicate that no improvement can be obtained, as the case which did best had had his acute infection eight years previously. (6) There is a distinct difficulty in infecting certain cases of post-encephalitis with malaria, as several of them who had never had malaria before have been inoculated on three different occasions without fever developing. (7) It would appear that, at any rate, a further trial of this method of treatment and a more extensive investigation over a larger number of cases is justified by these results.

I should like to take this opportunity of thanking Colonel S. P. James, of the Ministry of Health, for his help and coöperation in supplying anopheles mosquitoes, and Dr. H. A. Fielden, of Torquay, for his great help on the pathological side.

A further series of cases is under treatment and will be reported on in due course together with a later report on the above cases.

CHRONIC EPIDEMIC ENCEPHALITIS:
TREATMENT BY INDUCED MALARIA.

BY P. K. McCOWAN, M.D. EDIN., M.R.C.P. LOND., D.P.M.,
AND
L. C. COOK, M.R.C.S. ENG.,
ASSISTANT MEDICAL OFFICERS, WEST PARK MENTAL HOSPITAL, EPSOM.

CHRONIC epidemic encephalitis is a disease having sufficient resemblance to general paresis to have raised the hope that, after intentional malarial infection, it might show improvement parallel to that which is undoubtedly seen in the latter disease. This is the only reason that can be put forward to justify the treatment of chronic epidemic encephalitis by induced malaria. Both diseases are chronic infective processes affecting the central nervous system, notoriously resistant to any known treatment by drugs, and, once established, sooner or later are fatal. The few references in the literature to malarial treatment of encephalitics show that only an isolated case here and there has been dealt with, and that the reports have been published before the full effect of the treatment could be definitely appraised.[1] [2] The subject was discussed last year at the October meeting of the Office International d'Hygiène Publique, and Colonel S. P. James informs us that "Dr. Chodzko, of Poland, said that an Italian had obtained marked amelioration in two out of four cases of post-encephalitic Parkinsonism, but he could not give the reference." The reports from other countries where the treatment had been tried were unfavourable.

It therefore seemed advisable to try, if possible, to decide definitely whether at last some hope of cure could be held out to the unfortunate victims of this incapacitating disease. A unique opportunity for the experiment presented itself at this hospital, as all the facilities for applying the treatment were present, and over a hundred patients were available from whom a choice could be made. The writers have had many years' experience of the treatment of general paretics by this method, and a highly trained staff was available to coöperate in the careful nursing and the making of the necessary observations so essential if the attendant risks are to be reduced to a minimum. In the case of general paretics, what we regard as a full course of treatment is that the patient should have ten rigors with rise of temperature to 104° F. or over, and it was decided that this be aimed at with the encephalitics. This is a severe test of the strength of any patient, and as encephalitics as a whole are none too robust it necessitated a very careful watch being kept on the course of the disease. This was done by clinical observation of the patient and by examinations of the blood films taken quarter-hourly during the paroxysms of fever with a view to judging the extent of blood involvement from the malarial infection.

[1] Stransky: Ars Medici, 1925, iii., 285.
[2] Weygant: Wien. Klin. Woch., 1923, No. 47, p. 2164.

The Experiments Described.

The malaria was induced by the feeding of infected mosquitoes on the patient. This method was used in preference to the inoculation of infected blood, as in this way malaria fever is definitely transmitted, whereas with inoculation we are dealing with an artificial disease which is different from the real infection in many important points which need not be dwelt upon in this paper. The only disadvantage of the method used is that the fever is not so easily controlled by quinine, and two of the present series have had relapses of their malaria.

Fifteen male patients were chosen as representing different types and stages of the disease; five of these were allowed to run a full course and had ten or more rigors with peaks of 104° F. or over, in two it was considered advisable, owing to their physical condition, to terminate their malaria after they had had eight rigors with peaks of 103° F. or over. It is on these seven cases that our conclusions are really based. One case showed signs of pulmonary mischief on the fourth day of his fever and, although quinine was promptly administered and his malaria checked as shown by blood films, he did not rally, and died three days later. Autopsy revealed extensive bronchopneumonia, but nothing to suggest that his death was due to malarial infection per se. All five patients who ran a complete course were youths between 17 and 24, and, without exception, had regular strong rigors and stood their course excellently. Even in them, however, the combined effect of the malaria and the forced inactivity incident to it led to considerable feebleness from which recovery was extremely slow. Compared with the average case of general paralysis the convalescence of these cases was very protracted, and they did not reach their pre-treatment strength for very many weeks. It seemed that the remaining seven patients had escaped infection, but after the prolonged incubation period of eight months in one case and nine months in two cases, three of these patients commenced their malarial fever.

Negative Results of Treatment.

By this time, however, we were satisfied that the treatment was in no way beneficial, and we no longer felt justified in subjecting these patients to the dangers of a prolonged course. We therefore exhibited quinine after a few days' fever, having in the meantime found malarial parasites in blood films from each case, and so proved beyond possibility of doubt the nature of their fever. These three cases, although of little importance from the point of view of the effect of malaria in encephalitics, are of considerable interest to students of malaria on account of the long incubation period of their attack. It should be noted that this was a true incubation period and not a relapse following an abortive primary attack. The temperature of these patients was taken thrice daily for six weeks following their being bitten by the mosquitoes, a period which amply covered the usual time of incubation, and even after that they were under close observation for any evidence of the commencement of malaria. All three cases were infected from the same strain of mosquitoes, as was also one of the four remaining cases who have not yet shown any signs of infection.

Conclusion.

In the short summary of each case, which is given below, no details as regards mental symptoms or neurological signs are stated, as these were entirely uninfluenced in every case. The only result of the treatment was a debilitating effect on the general health of the patients, a debility which was very prolonged owing to the poor recuperating powers of the encephalitic, and we have no hesitation in condemning malarial therapy as a thoroughly useless and unjustifiable method of treatment in these cases. It is by no means devoid of danger and, even in those cases who would appear to have recovered from its effects, it may well have left permanent traces. It may have further weakened the already poor defensive mechanism against disease of which they were possessed, and have prevented that step towards improvement which care of the general health causes in the encephalitic. It is well known that it is in early cases of general paresis that most benefit occurs from malarial therapy, and it might be objected that owing to the comparatively advanced type of case dealt with here, a fair chance was not given to the treatment. This objection would be justifiable if advanced cases of general paresis showed no benefit following malarial treatment, or if even the slightest transient improvement had been obtained in one encephalitic patient. Neither of these propositions can be maintained, however, as we can abundantly testify. Our results are also in keeping with the results obtained from other forms of intercurrent fever in the two diseases. It is a well-established fact that in general paresis transient improvement often follows intercurrent febrile diseases, and many forms of treatment have in the past had a passing popularity because of this. In fact, the present malarial therapy was an outcome of this line of treatment. Nothing analogous to this occurs in chronic epidemic encephalitis. At different times we have treated our encephalitic patients with various forms of artificial fever therapy, and two of them have had well-developed attacks of erysipelas with hyperpyrexia, but in no case did any improvement, transient or otherwise, occur.

Summary of Cases.

P. H.—24 years, advanced Parkinsonian, bitten Jan. 12th 1927, by one mosquito; incubation period 10 days. He had 10 peaks of over 104° F., of which the highest was 106°. He stood his course well, but remained enfeebled from for 2 or 3 months. Since then he has made no improvement, and is rather slower and weaker than before h treatment.

M. E.—18 years, advanced Parkinsonian, bitten Jan. 17th by two mosquitoes; incubation period 18 days; 10 peaks over 104° F., highest 107·2° F. Stood course well, convalescence slow. No change.

S. W. T.—17 years, moderate Parkinsonian, apache tendencies, bitten Jan. 17th and Feb. 5th; incubation period 14 days; 10 peaks over 104° F., highest 106° F., and 7 peaks over 103° F. Stood course well, convalescence slow. No change.

S. M.—17 years, moderate Parkinsonian, apache, bitten March 4th by two mosquitoes; incubation period 13 days; 11 peaks over 104° F., highest 107° F. Stood course well, slow recovery. No change. Malarial relapse June 12th.

C. R.—19 years, moderate Parkinsonian, bitten April 20th by five mosquitoes; incubation period 13 days; 10 peaks over 104° F., highest 105·4° F. Stood course well, recovery slow. No change.

H. S.—20 years, moderate Parkinsonian, apache, bitten April 20th by three mosquitoes; incubation period 13 days; 6 peaks over 104° F., highest 105·4° F., and 2 over 103°. He developed slight jaundice necessitating termination of his treatment on the twelfth day. Recovery was very slow. No change.

G. H.—48 years, moderate Parkinsonian, bitten April 20th by six mosquitoes; incubation period 13 days; 5 peaks over 104° F., highest 105·2° F., 3 peaks over 103° F. He became very feeble, and it was considered advisable to intervene on the eighth day. Recovery was extremely slow and he has never altogether regained his lost ground.

H. W.—39 years, moderate Parkinsonian, bitten April 20th by three mosquitoes; incubation period 13 days; temperature remained elevated. Became cyanosed, respiration and pulse rapid. Malaria stopped on fourth day, but bronchopneumonia intervened and death took place three days later.

In conclusion, we would thank the medical superintendent of West Park Mental Hospital, Dr. Norcliffe Roberts, for permission to publish our results, and Colonel James for directing our attention to the foreign literature of the subject.

THYROID MEDICATION IN SKIN DISEASE.*

BY P. B. MUMFORD, M.D. MANCH., M.R.C.P. LOND.,

ASSISTANT MEDICAL OFFICER, MANCHESTER AND SALFORD HOSPITAL FOR DISEASES OF THE SKIN; ASSISTANT TO THE DERMATOLOGIST, ROYAL INFIRMARY, MANCHESTER; VISITING PATHOLOGIST, PARKSIDE MENTAL HOSPITAL.

THE administration of thyroid by the mouth has been used with varying success by many workers for almost every disease of the skin. Owing to its frequent failure to produce amelioration, its use has fallen into disrepute of recent years. The failure may perhaps have been due to lack of care in picking suitable cases, and also to the absence of any recognised criteria by which cases for thyroid medication should be chosen.

Increase of thyroid hormone in the blood stream causes: (1) an increased metabolism of the skin; (2) an increased superficial and peripheral circulation; and (3) an increased vascular response to irritant. These three results, all interdependent, would be of great value in combating the progress of many chronic diseases of the skin, were it not for the many contra-indications to its routine use.

Thyroid may be given in three groups of skin diseases: (1) Where there is definite evidence of subactivity of this particular gland—e.g., the xerodermia of myxœdema. (2) Where there is no evidence of gross glandular subactivity, but in which the effects of thyroid medication may be expected to remove the causes, or relieve the results, of the skin disability. These are cases in which thyroid "poisoning" forms a method of treatment—e.g., certain cases of pernio. (3) Diseases due to some obscure disorder of metabolism in which a general increase of vital processes may be expected to remove the causative agent—e.g., certain cases of chronic urticaria.

These groups may now be studied in detail with examples.

Subactivity of the Thyroid.

Group 1.—Where there is definite evidence of subthyroidism, the dry, harsh skin of a true case of myxœdema, or the less dry skin of a patient definitely suffering from reduced thyroid activity, will yield to thyroid medication in nearly every case, and a week or two of comparatively mild doses of the gland will give marked improvement. Whenever a skin disease, even one of unknown ætiology, is found in a patient who is mentally slow, has a sluggish pulse, dry skin, a partial diffuse alopecia, or other symptoms suggestive of subthyroidism, then treatment by the gland may be rationally employed, and surprisingly successful results often follow. In a case of epidermolysis bullosa where there was definite general evidence of such subactivity, thyroid medication was found not only to give a lasting cure, but also a marked improvement in general symptoms. In other cases of epidermolysis bullosa thyroid has proved valueless. This particular case was complicated by deficiency of secretion, and it may have been that the readjustment of this function was accompanied by the removal of some unrecognised ætiological factor.

O. Gans quotes a case of a 3-year-old child with dry, infected, and malnourished skin, in whom thyroid extract alone gave a cure. W. Falta quotes a case of severe irritation in a patient whose skin was "thick, cool, and cyanotic," and did not show any sensible perspiration. Glandular extract produced smooth, elastic, and healthy skin free from itching. J. Hertoghe quotes cases of chronic eczema with thick, infiltrated skins, who manifested signs of reduced thyroid activity and whose lesions yielded to thyroid medication. A chronic type of urticaria may be found in true myxœdema and in cases suggesting a mild form of the disease. Relief following thyroid medication may be due to the direct effect of the gland on the skin or to the removal from some other part of the system of an agent causing the urticaria. M. L. Ravitch[1] quotes nine cases of chronic urticaria cured by thyroid medication.

Malcolm Morris,[2] in a paper on the internal secretions in relation to dermatology, referred to the use of thyroid for a very wide range of diseases of the skin. He concludes that it is of greatest therapeutic value where there are certain evidences of reduced activity of the gland, such as chronic rheumatism, obesity, and mild dryness of the skin. He found it of value in chronic psoriatics who manifested these symptoms. He suggested that it might also be employed with success in the eczema of over-fat babies and in ichthyosis.

Thyroid medication will often produce improvement in general symptoms as well as local symptoms, especially at the menopause. Cases occur where thyroid medication produces an increase of weight, improved mental condition, a brighter and happier outlook on life, and an improvement in the health of the skin in particular. Such cases appear to be in specific need of thyroid. The increase of weight is not altogether an anomaly; it is probable that the relief of the skin irritation and the increased comfort resulting are potent factors in improving the general health and physique of the patient.

Cases for "Thyroid Poisoning."

Group 2.—In this group an attempt is made to combat manifestations of disease by mild thyroid poisoning. Amongst the results of this will be decrease of peripheral tone and increase of sweating, of sebaceous activity, and of skin metabolism. If any of these latter are thought likely to counteract the results of the skin disease, then thyroid medication may be rationally employed. (Thyroid medication may, however, promote a disease which is already associated with sweating or with erythema of arterial origin.) It is possible that chilblains are in part due to an exaggerated physiological response to cold by the superficial blood-vessels. Thyroid medication relaxes peripheral tone and gives a general physiological dilatation of vessels secondary to raised metabolism; it counteracts to some extent the arteriolar spasm, which is one of the causative agents of the pernio lesion. Treatment of chilblains by thyroid extract is, in picked cases, rational rather than empirical.

In skin conditions where there is general infiltration and thickening in the absence of any definite underactivity of the thyroid, administration of the gland may produce improvement by increasing superficial circulation and nutrition. Very minute doses may bring this about; in one case, with an extraordinary sensitivity to thyroid, improvement ensued in the skin, although acute thyroid poisoning followed ½ gr. thyroid gland three times daily. Byrom Bramwell,[3] after accidentally producing a general exfoliation from thyroid poisoning, had a number of almost miraculous cures of psoriasis. His results were produced in one case at least by the development of a marked hyperthyroidism.

There are several conditions of the skin grouped rather loosely under the headings of "ichthyosis" and "xerodermia." In many of these thyroid medication is of some value, though occasionally it is definitely contra-indicated by other characteristics. All degrees of dryness are found in human skin varying from a mild follicular hyperkeratosis confined to the posterior border of the upper arm—a condition frequently associated with an impaired peripheral circulation—to a general thickening and dryness of the skin of the whole body. Amongst these groups is a class of individual having an "ichthyoid" skin, best described as leathery in texture, in whom grease secretion is little diminished, though the perspiration may be reduced. These persons are usually free from any general disorder of the skin, and it is only an outside observer who realises that they are abnormal. They may, however, manifest

* Based on a paper read before the Bolton Medical Society.

intercurrent diseases of the skin, and may respond to thyroid medication because of an improvement in the basis on which the disease occurs. This applies particularly to patients in whom perspiration is diminished.

In all degrees of peripheral dryness thyroid medication may be of value. The disadvantage of a routine treatment on these lines is that it occasionally induces a temporary attack of hyperthyroidism with consequent distress. Thyroid therapy may be contra-indicated by cardiac, metabolic, or digestive disorder. The skin condition may be relieved, but the other manifestations are sufficiently severe to prevent further treatment by thyroid. Some cases develop signs of overdosage before there is any relief of skin symptoms. G. R. Murray[4] suggested that there might be a certain constituent ingredient of the gland with particular influence on skin metabolism. Definite proof of this has not been forthcoming, although it is clinically common to find a typical skin remaining in myxœdema patients who, under thyroid medication, have demonstrated tachycardia, diarrhœa, loss of weight, and other evidences of overdosage. Falta suggests that "dysthyroidism" does not exist, but that these anomalies are due to a varying type of response in different individuals—one responding easily to treatment of obesity, though poorly to treatment of xerodermia.

Skin conditions usually associated with myxœdema may be found in individuals who have no such deficiency. Falta quotes several cases of apparently typical myxœdematous skins in persons of normal glandular activity. Such cases do not react well to thyroid medication.

Provided the action of the gland could be confined to local effects, its use would be much wider than at present, but treatment of skin conditions with thyroid gland to the point of poisoning is hardly justifiable. It is to be noted that Bramwell, who was the first to introduce this treatment for psoriasis, states that a pulse of 130 is by no means a contra-indication. In view of recent work on the possibility of producing diabetes or exophthalmic goitre by excessive dosage, such a pulse would to-day prevent the further administration of thyroid. He concludes his remarks by saying that thyroid medication of psoriasis will occasionally give a brilliant result, often improve the condition, and sometimes have no effect. Subsequent work has done little to disprove these conclusions. I have noted that psoriasis can exist in the presence of Graves's disease, and it seems clear that treatment of psoriasis by thyroid gland is by no means specific.

Metabolic Disorders.

Group 3.—The third and very indefinite group of diseases of the skin which may be treated by thyroid gland consists of certain diseases of obscure ætiology which may be associated with internal derangement of metabolism. Such derangements are occasionally remedied by the direct effect of the gland. For example, it is likely that certain diseases of the skin are due to intestinal irritation or to absorption of unusual products of digestion, factors known to affect the superficial vascular system. They may result from chronic constipation; thyroid extract increases intestinal peristalsis, and so may directly remove the causes of disease. A case is quoted by A. Fabini in which chronic urticaria of nine years' standing was removed by thyroid medication. A nurse (E. K.) under the author's care showed chronic urticaria and also signs suggestive of thyroid deficiency. She was relieved of both by thyroid medication. Whether the relief of the urticaria was due to the relief of constipation by the gland, or whether to a specific vascular effect, it is impossible to say.

Cases of localised sclerodermia sometimes show a marked improvement under this treatment; such results are either coincidence or due to the removal of a quite unrecognised ætiological factor. A local and specific effect on the area of skin involved is unlikely. Many cases of sclerodermia are reported as coexisting with glandular hyperactivity (Falta).

There does not seem to be any rational basis for the treatment of such conditions as lupus vulgaris by thyroid extract, except in so far as the general effects exercised by the gland on the system may improve the general condition of the individual.

Dosage.

The dosage of thyroid will depend on the age, weight, and condition of the patient, and the degree, if any, of subthyroidism present. An adult with slight myxœdema should commence with gr. 3 of the dried extract daily; an adult showing little or no clinical evidence of glandular deficiency can take gr. 1½ daily without danger. The dose is very slowly increased at monthly intervals until there are manifestations of slightly excessive intake or signs of improvement in the skin. The weight and pulse-rate should be taken weekly and noted on the patient's history sheet.

Some patients are sensitive to thyroid gland, even gr. ½ being excessive. In such cases the dose must be much reduced if the treatment is to be continued. A very minute dose may be sufficient to improve the skin condition without giving any discomfort.

Prognosis.

Prognostic points are:—

(*a*) Skin diseases with an onset at any of the transitional periods of life, such as puberty and menopause, are often temporary, and in part due to alteration of thyroid activity, balance being reassumed later.

(*b*) If thyroid medication proved of value in the early stages of treatment then prognosis, if thyroid is continued, is good. The gland can be taken in small doses over long periods without risk.

(*c*) In ichthyotic skins where there are signs of general hypothyroidism, and particularly if there is absence of sweating, a good prognosis may be made. Where sweating occurs normally, the prognosis for the disease for thyroid medication is generally poor.

(*d*) In children, if thyroid medication is beneficial there is often good prospect of improvement at puberty.

A NOTE ON THE AMBULATORY TREATMENT OF VARICOSE ULCERS.

BY JAMES DEVANE, M.B. DUB., D.P.H.,
PHYSICIAN, ST. ANNE'S SKIN AND CANCER HOSPITAL, DUBLIN.

To the general practitioner a reliable method of treating varicose ulcers must be a subject of more than passing interest. A new method of approach to the Gasserian ganglion is a theme for the elect but a new method of treating varicose ulcers has an appeal to every doctor. Varicose ulcers and the poor are always with us.

I have had clinical experience extending over 100 cases of the various modern methods of treatment of varicose ulcers, and in every case have seen results immeasurably better than the old lint and zinc oxide therapy. Modern treatment depends on two factors: support to the flaccid vessels and extra support at the point of lowest vitality—the site of the ulcer itself.

The varicose ulcer is due to venous stasis, and as a consequence, impaired nutrition, with often superimposed bacterial infection. It is at once a local and a systemic manifestation, and to get result local and systemic therapy must both be employed. Assuming the obvious natural therapeutic agents

food, air, and intestinal disinfection, the essential treatment is first to ensure as much local sterility as possible, then to give support to the vessels of the leg, and finally to give extra support to that point where the tissues are weakest and have broken down —the ulcer itself.

To effect this I have tried the following methods. (The leg in each case has been washed in hot soap and water or some bland antiseptic from the toes to the knee. The surface of the ulcer has been cleared of slough and débris ; the edges and the base, where necessary, touched up with caustic.)

1. Dress ulcer with a suitable medicament such as zinc, iodoform, or neoform ; place a few layers of sterile gauze over the ulcer, and on top of this, extending over the edges of the ulcer, sterile lint. Bind leg with crêpe bandage from middle of foot to knee.

2. Dress ulcer as above. Instead of lint use a rubber sponge to extend half an inch all around edges of ulcer, and use crêpe bandage as above.

3. Proceed as in 1 and 2; use a zinc glue bandage instead of crêpe.

4. Unna's paste dressing as described below, with or without sponge, and with or without window opening.

Of all these methods I have found the Unna's paste method to give the best results. The method takes time, but will repay the energy expended. The most intractable varicose ulcer will heal. The patient will not lose one day's work, will not stay one day in bed, and will feel a distinct improvement from the moment the first dressing is put on. This is the method :—

1. Cleanse leg well with warm water and soap. Cleanse ulcer with mild antiseptic, separate sloughs. Touch up edges where necessary with caustic.

2. Elevate the leg. Allow heel to rest on a block for some minutes.

3. Pack ulcer with ung. zinc. ox. until zinc. ox. and surrounding skin are on same level.

4. Cover ulcer with three or four layers of sterile gauze.

5. In some cases place some layers of sterile lint *over* the gauze, and in other cases place a thin layer of rubber sponge *over* the gauze. This extra support is indicated where discharge is not too copious. It is better, however, to omit 5 until some experience has been gained and pass from 4 to 6.

6. With a brush paint the leg from the middle of the foot up to within a few inches of the knee with Unna's paste. At this stage the gauze covering the ulcer is painted with the paste.

7. Commencing from the middle of the foot, roll an ordinary two and a half inch cotton bandage from the middle of the foot to within a few fingers-breadth of the knee-joint. As each turn of the bandage is rolled it should be painted with Unna's paste all around.

8. Allow Unna's paste to dry.

9. If there be no pain, no obstruction-symptoms (i.e., swelling, numbness, discoloration, &c., of the foot), no excessive discharge, allow the bandage to remain on for one week. If there be any of these symptoms take down the bandage and repeat process when symptoms have gone.

10. The second similar dressing, in the absence of any of the symptoms mentioned, might remain on for two weeks.

11. The third similar dressing for three weeks. At this period even the most recalcitrant ulcer should be well on the way to recovery.

It is scarcely necessary to add that Unna's paste is solid when supplied by the chemist, and should be brought into solution by placing it over steam, or placing the jar which contains it in a vessel of boiling water.

By this method we ensure: (*a*) That the leg and ulcer are not contaminated from outside by daily handling, dirty lint, and creviced loose bandage. (*b*) That we get equal traction along the whole leg and that the vessels get adequate support. (*c*) That the ulcer itself is under extra pressure and is bathed in mollifying zinc.

To simplify the routine dressings, I have recently experimented with a bandage of my own which will eliminate the tedious painting with the Unna's paste, and will, I hope, give just as good results. I have not, however, tried a sufficient number of cases to write with authority on this method.

Clinical and Laboratory Notes.

A NOTE ON ULTRA-VIOLET RADIATION IN THE TREATMENT OF HERPES.

BY M. WEINBREN, M.R.C.S. ENG., B.SC. S. AFRICA, D.M.R.E. CAMB.,

MEDICAL OFFICER IN CHARGE OF THE X RAY AND ULTRA-VIOLET DEPARTMENTS, QUEEN'S HOSPITAL, FROGNAL, SIDCUP ; HON. ACTINOTHERAPIST, MOUNT VERNON HOSPITAL.

THE treatment of herpes in its various forms by ultra-violet rays has been advocated in most of the books dealing with ultra-violet therapy. Although none of the authors have published large series of cases, all record good results in the cases they have treated, some actually claiming to have aborted herpes in the early stages. All have used the mercury [1] vapour lamp, air-cooled for treatment and water-cooled for aborting attacks. The dose advocated varies ; Plank [2] recommends blistering, although he reports a case which improved rapidly without such vigorous treatment. Others suggest doses which would correspond to a second or third degree erythema.[3] [4]

It is not easy to collect long series of cases of herpes, nor is it always possible to be certain that the particular treatment given was actually responsible for the improvement. There is, however, little doubt that ultra-violet treatment was of benefit in the nine cases I have treated, of which the three following are typical.

CASE 1.—Five weeks after a course of stovarsol and auremetine for amœbic dysentery the patient began to complain of itching in the left groin and noticed a number of vesicles. The itching was so intense that it kept him awake the whole of the first night and he said that he could not bear anything touching the skin. He was given five minutes at two feet with the air-cooled Hanovia lamp (a second degree erythema). This dose was repeated every day for four days. The first exposure relieved the itching and the next day there were fewer vesicles. After the fourth exposure all the vesicles disappeared ; there was no itching and there was no scarring of the skin. The stovarsol was probably not responsible for the herpes in this case.

A control case, not treated with ultra-violet rays, occurred in the hospital at the same time and with very similar distribution, and the vesicles and itching persisted for three weeks. The patient had previously been given a course of ultra-violet treatment and his skin had become well pigmented. He was not on ultra-violet treatment at the time of the attack of herpes. Serious scarring resulted.

CASE 2.—The attack of herpes zoster came on during a course of ultra-violet treatment for anæmia. He was not receiving any arsenical drugs at the time. As a large area was affected, the opportunity was taken of observing the effect of doses of different intensity. Part of the area was treated with the "Alpine Sun," the other part with the "Kromayer." Very heavy doses from both lamps were necessary to obtain any reaction, his skin being well pigmented as the result of his general ultra-violet treatment from the carbon arc. Three days after the first exposure most of the vesicles had disappeared, but there was still some irritation. The Kromayer only was then used to relieve the irritation, which cleared up with three more exposures. The heavier doses from the Kromayer were more effective than the doses from the Alpine Sun. There was no scarring or neuralgic pain after the treatment.

CASE 3.—A woman with a patch of herpes zoster was sent to the light department at the Mount Vernon Hospital by Dr. J. F. Halls Dally. The vesicles had been present four weeks and the patient was complaining of considerable discomfort which disturbed her sleep. One minute from a new Kromayer lamp in contact (heavy third degree erythema) removed the vesicles and relieved the discomfort. The dose was repeated only once two days later, and all discomfort ceased.

Three more cases were treated on similar lines with similar results. In these the herpes was not so severe, however, as in the cases described, and it is possible that they would have improved rapidly in any case.

As far as it is possible to draw conclusions from these few cases it would appear that: (1) general

ultra-violet treatment will not prevent the onset of herpes, nor will the pigmented skin prevent the appearance of vesicles or scarring (Cases 2 and 3); (2) local ultra-violet radiation will remove the vesicles and relieve the accompanying discomfort; (3) heavy doses are more effective.

I am indebted to the Director-General of Medical Services, Ministry of Pensions, for permission to publish this note.

THREE CASES OF ETHMOID DISEASE.

BY WALTER BROADBENT, M.D. CAMB., F.R.C.P. LOND.,

SENIOR PHYSICIAN TO ROYAL SUSSEX COUNTY HOSPITAL; CONSULTING PHYSICIAN TO ROYAL ALEXANDRA HOSPITAL FOR CHILDREN.

THE ethmoid and sphenoid sinuses are so deeply situated, and so difficult to get at, that inflammation in them is often not thought of as a possible cause of headaches. Such headaches are generally referred to the back of the head or are said to be deep in it. If pus is pent up in these cells, any extra infection may lead to a fatal meningitis, as the following cases show.

CASE 1.—A girl of 7 was suddenly taken ill with headache and vomiting and was very feverish. The next two days she was thought to be better by her mother, as she did not vomit, but she still had headache. On the fourth day she was delirious, so a doctor was called in, who at once sent her into hospital.

On admission her temperature was 101·6° F. There were sordes on the teeth and the tongue was furred and brown. She had much pain in the head. Though there was no actual retraction of the neck, the chin could not be got within 2 inches of the chest. Kernig's sign was well marked. The right toe reflex was extensor. There was no tenderness over the mastoids, and the ear-drums were normal. The pharynx and tonsils were red and swollen, but there was no secretion on them. There was no nasal discharge. There were no abnormal physical signs in the lungs, abdomen, or heart. On lumbar puncture turbid fluid under pressure was obtained, which contained very numerous pneumococci. She was given 5 gr. of urotropine four-hourly, and hypodermic antipneumococcic serum, but she died on the fourth day after admission.

Post mortem the lungs and other organs were quite normal. On opening the skull there was a meningitis spreading all over the brain, most severe in front of the pons. Both mastoids were opened and found to be normal. The dura mater over the right ethmoid was injected, and, when the bone underneath was cut into, it was red and inflamed. In the right ethmoid cells there was thick pus, evidently the origin of the meningitis.

CASE 2.—A man of 25 was admitted to hospital under me some years ago for headache, which he had had on and off for some time, but it had become worse lately, keeping him awake. There was no retraction of the neck and no Kernig's sign. His temperature and pulse were normal. His tongue was very furred. There was no albuminuria. A few days after a patient was admitted to the next bed with an acute streptococcal infection of the throat. The next day the man had a sore-throat, and his temperature rose to 100° F., the headache also becoming much worse. Two days later the neck was rigid, and Kernig's sign was present for the first time. Some swelling of the temporal and pre-auricular region on the right side was noted. Lumbar puncture gave a cloudy fluid, from which abundant streptococci were grown. On the following day there was swelling of both temporal and pre-auricular regions, more marked on the right side, and œdema of the eyelids as well. There was no nasal discharge. At the post-mortem there was extensive inflammation of the sphenoid bone and pus in the sphenoid and ethmoid sinuses, as well as a streptococcal meningitis. Evidently the headaches had been due to pus in the sphenoid and ethmoid sinuses, and the infection from the throat had lighted up a streptococcal inflammation of the bone and meninges. The œdema of the temporal and orbital regions was probably caused by blocking of the orbital veins and lymphatics by the inflammation of the sphenoid bone.

CASE 3.—A boy of 7 was admitted to hospital with marked proptosis of the right eye, the swelling having only begun a week before. The conjunctiva was bloodshot, and, on examining the optic disc, it was seen to be œdematous. There did not seem to be much pain. There was no nasal discharge. The whole contents of the orbit projected a good half inch in front of the level of the eyebrow, as if there was a tumour at the back of the orbit, but the swelling had all occurred in a week. The temperature was 99·6° F., and the pulse-rate 96. On blood examination there was a leucocytosis of 17,000.

I asked Mr. Fitzmaurice Kelly to see the case and explore the orbit. On making an incision on the inner side above the eyeball, he found pus over the ethmoid bone. He then lifted the periosteum and dissected it back, and opened the ethmoid sinus, which was full of pus. The proptosis soon went down, but it took some time for the sinus to close.

Another case may have been due to ethmoid disease. A lady, who had for a long time been subject to deep-seated headaches, was suddenly taken acutely ill with intense headache, vomiting, a temperature of 102·5° F., and a pulse-rate of 80. When she was seen next day in consultation there was marked evidence of intracranial pressure; her head could not be bent forwards and Kernig's sign was present. There was some tenderness on pressure just below the left eye. I was so convinced that this was another case of ethmoid disease that I asked that the sinuses should be explored. This was done the next day by a London specialist, who, however, said that he found no pus in the ethmoid or sphenoid sinuses, but the following day the temperature had come down, the headache was much less, the vomiting had stopped. The meningeal signs quickly cleared up and the patient got well. The pus in the ethmoid sinus in the first case, in which the patient died of meningitis, was so thick that it would not have flowed out if the sinus had been opened from the nose, and it seems to me possible that such pus might have been present under pressure in the last case, and the opening of the ethmoid sinus may have relieved the tension without, at the moment, causing pus to flow.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH

THE following are some 1926 statistics of six districts:—

Name of district and estimated mid-year population.	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.		
		All causes.	Tuberculosis.	Cancer.	Respiratory diseases with influenza.	Heart disease.	Diarrhœa under 2 years.	Infant mortality.	Maternal mortality

* Average of six years, 1921–26.

Newcastle-upon-Tyne.

Dr. Harold Kerr expresses the opinion that t population of the city did not suffer in health consequence of the strike. This fortunate state affairs was due to the excellent relief arrangemen

As one example, seven and a half more tons of free dried milk and two tons more of cost-price dried milk were supplied than in the previous year. The effect of the strike was also evident in the sunshine records. Thus at the Armstrong College 1085 hours of bright sunshine were registered as compared with 934 in 1925, whereas at the other station at Cockle Park some miles north of the city and in a rural area, 1449 hours were registered as compared with 1461 in the previous year. The clarity of the atmosphere in the town would have been greater still in 1926 but for the fact that much of the coal burnt was of grossly inferior quality. Dr. Kerr goes on to point out that much of the atmospheric pollution for which Newcastle has a bad name comes from the south of the river, and he welcomes the recent move for the formation of a regional smoke committee for Tyneside. He also points out that the city's tramways' power station contributes more than its fair share of smoke and handicaps the health department in dealing with other offenders. The general death-rate is the lowest on record. The towns in the north of England, however, owing to a greater density of the population and a greater shortage of dwellings compare unfavourably with the towns in the south. During the present year (1927) the University of Durham College of Medicine has taken steps to form a cancer investigation committee for the counties of Northumberland and Durham and for Newcastle-upon-Tyne. Fifty cases of small-pox were notified, some of them acute, but there were no deaths. Infantile vaccinations fell from 64 per cent. to 59 per cent. in 1926, but vaccination was "practically never refused by contacts."

There was one outbreak of suspected food poisoning, with three recognised cases and two deaths. Bacteriological examination revealed the presence of the dysentery (Flexner) bacillus in one of the fatal cases and in the intestinal contents of the patient who recovered. The same bacillus was identified in the case of three other members of the household who suffered no characteristic symptoms. Of seven patients with acute poliomyelitis, all survived, but two were left with permanent paralysis. Of three patients with cerebro-spinal fever two died, and eight of 24 cases of encephalitis lethargica were fatal. On June 26th Dr. Neil Maclay, the visiting oto-rhinologist of the city hospital, died suddenly. His work since 1921 had been an unqualified success in shortening the stay of patients in the hospital and in preventing deafness. Dr. W. Frank Wilson has been appointed in his stead.

Scarlet fever antitoxin has been administered to 3 patients with severe attacks. "If given at an early stage, the effect is almost magical, temperature falling rapidly, toxic symptoms disappearing, and general improvement occurring within 24 to 36 hours of the injection." A mercury-vapour lamp has been installed and has proved a success in promoting the convalescence of fever patients. Sickness among the nursing staff was heavy during the year. There were seven cases of scarlet fever and six of appendicitis. There were no cases of enteric fever or diphtheria, against which the nurses are protected by inoculation. Of the 56 city cases of ophthalmia neonatorum 1 died, 4 recovered completely, and in 1 baby the sight of one eye was left slightly defective. There are 18 registered blind persons in Newcastle, of whom 3 are stated to have been blind from birth, but there is only one blind child under 5 years of age. The infant mortality-rate of 88 is the lowest yet attained. The Byker ward had a rate of 130, while that in Osmond was only 40. Dr. Kerr points out that nearly half the deaths of infants are due to causes operating before birth, hence the importance of the antenatal clinics. There were 376 antenatal sessions in 1926 as compared with 319 in 1925. During the last five years the new cases attending the sessions have increased from 252 in 1922 to 1015 in 1926. The total number of births during 1926 was 6007. Dr. Kerr claims that the comparatively low maternal mortality from childbirth is largely due to the Princess Mary Maternity Hospital. The births in Newcastle are attended in about equal proportions by doctors, midwives, and this maternity hospital. As regards tuberculosis, Dr. Kerr considers that the prolonged period of industrial depression has interrupted the decline in the mortality from pulmonary tuberculosis, but that the greater attention now given to milk is causing the decline in the rate from non-pulmonary tuberculosis to continue. Out of 376 samples of milk examined for tubercle 15, or 4 per cent., were found to be infected. About 10 per cent. of the samples from Cumberland proved to be tuberculous. The new milk legislation has not as yet produced regular inspection of milk herds by county councils, but it has, at any rate, resulted in a thorough search being made for offending cows when tuberculous milk is reported. The cow population of the city includes only about 410 milch cows, seven of which were found to be tuberculous during 1926.

For some years Newcastle has insisted on the rinsing of empty milk churns before they are returned to the farmer. This has now become a legal requirement under the Order of 1926. About 24,000 churns were examined on the railway stations during 1926 and only 64, or 0·3 per cent., were found to be unrinsed. Of 3005 empty churns passing through Newcastle from retailers to farmers outside the city 47, or 1·5 per cent., were found to be unrinsed.

The wards in the city hospital used for advanced cases of tuberculosis are kept fully occupied, but this is not the case with the beds at the corporation sanatorium at Barrasford, owing to the difficulty in getting early cases. The corporation give precedence in the allocation of their houses to families affected with tuberculosis. In some cases, when the "tuberculous" family cannot afford to pay the rent, the preference is given to persons who have had to live in the same house, or the tuberculous family is given a better house vacated by an ingoing corporation tenant. An approved scheme for a public abattoir has been held up owing to financial stringency. Owing to the housing shortage "unfit" houses cannot be closed. During 1926, 441 corporation houses were completed, and at the end of the year 1854 were in course of erection. About 400 of these, however, were "compensatory" for houses demolished under improvement schemes. The demolition of houses in the three condemned areas goes slowly on, as the compensatory houses are completed. Up to the present the dispossessed occupants of the condemned areas "are revelling in the immense improvements in their conditions and by their care of their new homes and gardens are exhibiting all the symptoms of newly developed house-pride. Also, in spite of the hard times, there are very few arrears of rent."

Cardiff.

Dr. Ralph M. F. Picken's health report opens with a chart showing how the various branches of his department are arranged. There are seven assistant medical officers on the staff, none of whom devotes his or her whole time to any one section. The Newcastle report also opened with a similar chart, but in that case the medical officer of health is not school medical officer and there is not the same unification as in Cardiff. Dr. Picken says the low mortality of 1926 must be regarded as largely due to the absence of respiratory catarrh. One wave of influenza had just spent itself before 1926 came in and another became manifest in the first week of 1927. The inadequacy of the hospital accommodation for advanced infectious cases of tuberculosis in Cardiff and East Glamorgan has been considered by the Welsh National Memorial Association. Dr. Picken points out that Cardiff has not been receiving bed accommodation in proportion to its payment to the funds of the association. An investigation has been made of the place of birth of tuberculous patients and their parents with a view to arriving at conclusions with regard to the acquisition of immunity. According to one theory children brought up in a town acquire a certain degree of immunity by exposure to small doses of infection.

According to another, they inherit resistance from immune ancestors who have been the fittest to survive in unfavourable urban conditions; 80·2 per cent. of non-pulmonary cases were Cardiff born, while 61 per cent. of pulmonary cases were Cardiff born, and 84·8 per cent. of pulmonary cases were urban born. The percentage of Cardiff born parents was 42·2 for non-pulmonary and 21·4 for pulmonary cases. The smallness of the percentage in the case of the parents is explained by the rapid growth of Cardiff until quite recently. The fate of the infants born in tuberculous households has also been studied. Of 77 such infants born in 1926, 55 were found to be healthy in June, 1927, 6 were delicate, and 6 could not be traced. Ten had died, one from tuberculous meningitis, one from tuberculosis of the intestines, and the remainder from non-tuberculous causes. The foregoing are the crude figures of a much bigger investigation which it is hoped will be carried out.

Owing to an alarming outbreak of diphtheria, immunisation was carried out at three schools. Out of 1799 children under 10 years of age 579 were Schick-tested, 418 were positive, and 415 were immunised. Out of 578 children over 10, 174 were tested; 87 proved positive and 87 were immunised. Forty-four children under school age living near one of the schools were also immunised. No child who had had time to react to inoculation had developed diphtheria up to the date of writing. The number of first attendances at the two antenatal clinics was 865 and the births in 1926 were 4537. Some particulars were obtained of 771 expectant mothers (244 of them primigravidæ) who attended for the first time during 1926; 336 were confined in private dwellings, 358 in the maternity hospital, 23 in other nursing homes, 12 had miscarriages, in 2 cases the mother died before confinement, 2 were confined elsewhere than Cardiff, and 38 were not traced. More than half were confined away from their own homes and more than half required treatment for some defect. The crippled children under school age attending the orthopædic clinic number 201, and included 48 crippled by poliomyelitis, 11 by other palsy, 32 by congenital malformations, and 82 by rickets. The special venereal diseases centre for mothers and children was opened in February, 1926, and treated 63 cases of syphilis and 84 of gonorrhœa. This centre receives its cases chiefly from the antenatal, child welfare and school clinics. At the antenatal clinic a Wassermann test is done on each new patient. Another source of cases is the following up of ophthalmia neonatorum. It is found that the expectant mothers attend well, but after the birth of a healthy baby postnatal attendance is not so satisfactory. Of the 93 cases of ophthalmia notified 83 had unimpaired vision, 1 was blinded in the left eye, 7 died from other causes, and 2 left the district. House building proceeded faster during the year, but the overcrowding found by the staff of the health department "shows little or no abatement." Daily measurements of the ultra-violet radiation have been taken since May, 1926, which indicate that its amount is nearly ten times as great in midsummer as in midwinter.

Dr. Picken draws attention to the extremely unsatisfactory type of receptacle usually provided by householders for refuse. Leaving out the corporation housing estate, covered galvanised bins are only provided for 8·9 per cent. of the houses. There is a further percentage of 3·6 uncovered bins, and the remainder of the receptacles "consist of buckets, boxes, baths, &c."

Ipswich.

Dr. A. M. N. Pringle points out that in pre-war days there was a housing surplus of sufficient size to keep rents from advancing out of proportion to the capacity of the people to pay and so to permit of the population stepping upward from poorer to better houses. Now this surplus does not exist, the "stepping" process has stopped, and the worst houses are the most crowded. The slums are filled with people who cannot escape because of the stoppage of the population movement, and who are there in addition to the habitual slum-dwellers. In discussing the decline of tuberculosis, Dr. Pringle points out that the fall began long before the Public Health Act of 1875, and that its essential cause is to be found in the production of races immune to tuberculosis. An antenatal clinic is held once a week. The number of cases who attended during the last three years were 27, 61, and 123 respectively, whilst the births for 1926 numbered 1540.

Gillingham.

Dr. W. A. Muir reports that 50 per cent. of the children born attend the infant welfare centre at least once. The number of houses completed during the year was 203, the largest number for many years. The shortage of houses, however, continues. It is estimated that 200 new houses are needed annually to cope with the increase of the population and to replace demolished and dilapidated property. This estimated annual number has now been reached, but the leeway of the war and post-war years remains to be overtaken. The corporation have made an arrangement for the use of the joint hospital at Rochester for isolation purposes. The policy is adopted of domiciliary treatment of scarlet fever except in severe cases and where the premises are used for business purposes. There was a sudden outbreak of diphtheria in December, largely in connexion with St. Mary's school. An examination of all the pupils resulted in the discovery of one boy with severe nasal diphtheria. The closure of the school before the Christmas holidays apparently ended the outbreak. There is no municipal maternity home but 26 civilian cases were sent into the naval maternity home through the health department during the year. The corporation have not yet provided institutional treatment or the services of an obstetric specialist for puerperal fever. A number of small shops now retail sterilised milk in sealed bottles, and Dr. Muir thinks these shops should be regarded as "dairies" for the purposes of the new Milk Act. He also criticises the exemption from the milk order of persons who keep a cow or two for domestic use but occasionally sell surplus milk. Thirty samples of milk were examined for sediment by Sutherland Thomson and Co.'s sediment tester. Nine were classed as clean, ten as fairly clean, eight as dirty, and three as very dirty. The retailer is allowed to see the pad of cotton-wool through which the milk has been poured to illustrate the necessity of taking measures to ensure a cleaner supply.

Barry.

Dr. Percy W. Kent reports that the inhabitants are largely employed at the docks in connexion with the export of coal. The coal strike suspended the exportation of coal for nearly seven months, but the prolonged unemployment has not so far affected the health of the community. The urban district council has an accident and surgical hospital with accommodation for about 30. Dr. Kent urges the need for its extension by the provision of medical, children's and maternity wards. Eighty-eight children under school age received operative treatment at the school clinics, 22 for adenoids and enlarged tonsils, and 66 for dental caries. The six notified cases of ophthalmia neonatorum resulted in one case of impaired vision. Crippled children under school age are referred for orthopædic treatment to the Prince of Wales Hospital, Cardiff, the expenses in necessitous cases being paid out of a special fund. Thirty-three cases were treated during the year. The housing situation has been somewhat eased by the erection of houses by the council, but Dr. Kent says that overcrowding will continue until houses can be erected to be let at a rental of about 8*s.* per week.

Sheerness.

Dr. W. C. D. Hills reports for the united districts of Queenborough and Sheerness. Sheerness stands on alluvial land and the whole district is flat. A final sewage pumping-station is to be installed to allow for a population of 30,000. A new housing si

has been obtained and a contract made for the erection of 80 houses. It is estimated that 250 houses are required, but the growth of the town, apart from its use as a health resort, depends largely on dockyard developments. Another scheme of 40 new houses is in hand for Queenborough where there is also a housing shortage. Both districts suffered from outbreaks of poliomyelitis. In Sheerness there were 13 cases and one death; in Queenborough there were nine cases and one death. Dr. Hills thinks it is likely that this disease is spread by means of food, more especially milk, which has been contaminated by carriers. There is no hospital on the island and non-infectious cases needing hospital treatment are removed by the St. John Ambulance Brigade to Maidstone or Rochester, 18 to 20 miles away, while infectious cases are removed to a hospital at Sittingbourne. Dr. Hills performs the duties of school medical inspector for the county council in his two districts, and accommodation is provided at Sheerness for a branch county bacteriological laboratory. The Borough of Queenborough, with a population of 3062, had a birth-rate of 20·6 and a death-rate of 10·4. Its occupations are mainly pottery, glue, chemical, and glass works. The breaking up of war vessels has now ceased and a decline in the population is probable.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 8TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 149 (last week, 122); scarlet fever, 2262; diphtheria, 1158; enteric fever, 100; pneumonia, 736; puerperal fever, 35; puerperal pyrexia, 88; cerebro-spinal fever, 4; acute poliomyelitis, 45; acute polioencephalitis, 2; encephalitis lethargica, 20; continued fever, 2; dysentery, 7; ophthalmia neonatorum, 103. No case of cholera, plague, or typhus fever was notified during the week.

Of the cases of acute poliomyelitis and acute polioencephalitis taken together 11 were notified from the East Riding of Yorkshire (9 of these from Hull), and 8 from the West Riding (5 of these from Swinton). The dysentery notifications have returned to their normal level.

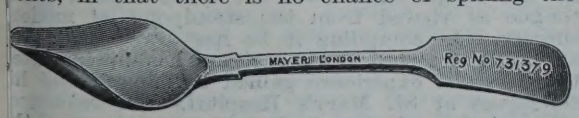
As the result of the further investigation of three cases reported in the newspapers as "mysterious disease in Warwickshire," in Warneford General Hospital, Leamington Spa, it has been established that these three patients are suffering from typhoid fever. It is anticipated that the other cases in the Southam Rural District will prove to be of the same character. The source of the infection has, as yet, to be ascertained.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 14 (1) from measles, 8 (2) from scarlet fever, 19 (1) from whooping-cough, 34 (6) from diphtheria, 85 (14) from diarrhœa and enteritis under two years, and 28 (6) from influenza. The figures in parentheses are those for London itself. The number of stillbirths registered during the week was 235 in the great towns, including 45 in London.

New Inventions.

AN INFANT'S FEEDING SPOON.

THE need for a better form of spoon for the feeding of small infants has been long felt and I have, therefore, designed a spoon which seems to fulfil all requirements, in that there is no chance of spilling the



contents round the child's mouth during feeding. It is also particularly useful in cases of prematurity or hare-lip. The figure explains itself.

The spoon is made by Messrs. Mayer and Phelps.

E. A. BARTON, L R.C.P. Lond., M.R.C.S.

Reviews and Notices of Books.

MALARIAL PSYCHOSES AND NEUROSES:

Their Medical, Sociological, and Legal Aspects. By WILLIAM K. ANDERSON, M.D., F.R.F.P.S. Glasg., Visiting Physician, Eastern District Hospital, Glasgow; Teacher of Clinical Medicine, Glasgow University. London: Humphrey Milford, Oxford University Press. 1927. Pp. 395. 42*s.*

IN this book Dr. Anderson dwells at some length upon the effects of malaria in the remote past, and in a historical survey traces malaria from Egypt to Greece, and then to Rome. Frequent references to classical writers illustrate his main point—namely, that malaria has a degrading effect upon the character both of the individual and of the race. He regards the fall of these ancient empires as being partly brought about by the malarial mosquito, the conditions of civilisation of those times being eminently suitable to the rapid growth of the anopheles. In dealing with the pathology of the disease he emphasises its protean nature and discusses it broadly under three headings: (1) conditions affecting the blood-vessels (sporulation, &c.); (2) toxic conditions; (3) sympathetic and parasympathetic interaction. The divisions are well described, and the sympathetic parasympathetic interaction theory is worthy of note; it postulates that the prodromal stage of the rigor is one of vagotonia passing into sympatheticotonia during the first part of the paroxysm (the cold phase), and later into vagotonia during the sweating phase of the paroxysm. A large number of physical conditions are described under the various headings, and are usefully illustrated by case-histories and post-mortem notes.

In the section on malarial psychoses nearly all psychotic conditions are included. While in one place they are spoken of as malarial in origin, on another page the author states that "all malarial psychoses are initially confusional states, and all other mental states are further developments at a later stage of certain features on the basis of confusion." Later he suggests that malaria may act by revealing a latent constitutional weakness, such as manic-depressive insanity of dementia præcox. He argues (p. 101) that since malaria is a potent tissue poison capable of damaging any and every tissue to any degree of extent, the clinical features of any case will vary according to the degree of the damage done. This will be readily accepted, but hardly leads us to postulate a definite malarial psychosis or psychoses as Dr. Anderson does. The theory that the psychotic or psychoneurotic condition which may be ushered in as a result of malarial infection is dependent upon the individual make-up of the patient, in accordance with Bleuler's theory of the reaction type, seems more probable.

The title of this book gives no idea of its scope, and implies a limitation which does not really exist. Malaria is dealt with from every possible aspect, and, indeed, the book will, we think, be of more value to all who come directly in contact with the ravages of the parasite than to the alienist or neurologist in this country.

ANOPHELINE LARVÆ.

An Illustrated Key to the Identification of the Anopheline Larvæ of India, Ceylon and Malaya, West of Wallace's Line. With Practical Notes on Their Collection. By C. STRICKLAND, M.A., B.C., Professor of Medical Entomology in the School of Tropical Medicine, Calcutta; and K. L. CHOUDHURY, M.B., D.P.H., Chief Assistant in Malaria Surveys of Assam and Bengal. Calcutta: Thacker, Spink and Co. 1927. Pp. 67. Rs.4.8.

THIS work is a sequel to the "Short Key to the Adult Anophelines," published by the senior author in 1925; its object is to help those who are engaged in antimalaria measures in the Indo-Malayan region.

Too often malaria surveys are conducted by men who make use of the data obtained by hatching out adults from anopheline larvæ which they have collected in the field, not realising the amount of labour lost in this procedure. Much time will be saved by making the best use of the material collected, and a simple method of identification of larval characteristics should be available to all observers. This book supplies illustrative diagrammatic figures of the various larvæ, and instructions as to their collection. Appendices are added on catching adult anophelines, equipment, organisation of staff, methods of packing and dispatching specimens, and, together with a short bibliography, complete a book which admirably fulfils the object for which it was designed. The work is inscribed to Sir Ronald Ross, who contributes a foreword. It is printed on specially durable paper in large, clear type.

TOXICOLOGY.

Diagnosi e Terapia clinica degli Avvelenamenti. Guida per Medici e Studenti. By Dr. G. CORONEDI, Professor of Pharmacology in the University of Florence. Florence: G. Barbera. Pp. 310. L.30.

THIS small text-book contains much valuable information, well arranged and excellently printed. The first part treats of poisoning in general, its symptomatology, course, result, and pathological anatomy. A novel arrangement takes the reader through the effects of poisons on the various systems of the body. Some good coloured plates show the different pictures produced on slides by the addition of a drop of the suitable reagent to the gastric contents in poisoning by lead, silver, arsenic, antimony, mercury, and copper. Reactions for alkaloids and glucosides are dealt with at length. Several blood tests for use in carbonic oxide poisoning are described with coloured illustrations; the reactions of Zaleschy, Salkowski, Katayama, and Coronedi are not commonly performed in this country. In the chapter on diagnosis the differentiation between poisoning by various narcotics is set out from the pharmacological as well as from the clinical standpoint. Many pages are devoted to treatment and the mechanism of the various antidotes is fully discussed. The second part of the book deals alphabetically with every substance which is known or considered to be a poison, including alcoholism, morphinism, nicotism, snake-bite, and botulism. Even such less well-known poisons as picrotoxin, abrus precatorius, vanilla, and lupin seeds find a place in this book, and are described so minutely that a table showing the differential diagnosis between poisoning by lupin, belladonna, cicuta, and aconite occupies a prominent place. In the short bibliography with which the work ends the only references to English authors are to the work of Lauder Brunton, whose book on pharmacology and therapeutics was translated into Italian by Tamburini, and published in Milan in 1901, and to a communication by Hegar and Zunz, made at the International Congress of Medicine held in London in 1913; but in spite of the omissions Prof. Coronedi's book is an excellent work of reference.

MANUAL OF PROCTOLOGY.

Second edition. By T. CHITTENDEN HILL, M.D., F.A.C.S., Instructor in Proctology, Harvard Graduate School of Medicine. Philadelphia and New York: Lea and Febiger. Pp. 294. $3.50.

IN a small book of 294 pages Dr. Chittenden Hill has succeeded in giving a clear and practical account of diseases of the rectum. Certain chapters deserve special commendation, particularly those on ulceration of the rectum and colon, the handling of which difficult subject will be found most helpful. We are glad to see that in the chapter on rectal abscesses the author carries on the campaign against the late and inadequate incision which is too frequently the cause of fistula in ano. The chapters on fistula, hæmorrhoids, prolapse, and pruritus are all very good. In the treatment of pruritus ani, under-cutting operations, such as Ball's operation and its modifications, are not even mentioned; this omission seems to be a good way of emphasising the fact that careful search for the cause of the pruritus and its adequate local treatment are successful in the great majority of cases. A few small points call for criticism; we do not agree that complete division of the external sphincter muscle is needed in the incision of all anal fissures, nor do we approve of the advice to stretch the sphincters as a preliminary to all operations for internal hæmorrhoids. The author advises immediate operation in cases of thrombosed and sloughing internal piles, however septic they may be. We are opposed to this line of treatment; operation in such cases is almost certain to be followed by a tiresome ulceration. Treatment on expectant lines, by baths and antiseptic compresses, leads to spontaneous cure in the large majority of cases, and if operation is needed later it can be done when the sepsis has cleared up. In the section on cancer of the rectum the author states his preference for a combined operation. The last chapter, on radical operation in cancer of the rectum, is written by Dr. Robert C. Coffey, who describes his two-stage abdomino-perineal excision, with his various methods of draining the devascularised bowel pending the second operation. As yet we believe this method has not been extensively tried in this country, and though there are obvious disadvantages in the operation, it appears to be a reasonable method of dealing with a high growth in a patient whose general condition forbids a one-stage abdomino-perineal excision. The text is clear and the illustrations are remarkably good.

FUNDAMENTALS OF DERMATOLOGY.

By ALFRED SCHALEK, Professor of Dermatology and Syphilology, University of Nebraska. Philadelphia and New York: Lea and Febiger. Pp. 239. With 54 illustrations. $3.

THE presentation of knowledge in a condensed form is a thankless task. Although it may well be of some temporary value to the profession, it adds nothing to science, and mostly but little to the author's reputation, but those practitioners who have no leisure for serious study often welcome a brief outline and find it useful. There are some original features in this little book. The various skin diseases are arranged in alphabetical order, and dealt with under the sub-headings of classification, definition, symptoms, ætiology and pathology, and treatment. Some wise observations and warnings are grouped together modestly as "dermatological aphorisms," separate paragraphs on the anatomy and physiology of the skin in general diagnosis, and some notes on general therapy are included. The compilation follows the lines of the standard text-books, and has been well done. The illustrations are not clearly reproduced and will not help much in the difficult problem of diagnosis.

THE TONGUE AND ITS DISEASES.

By DUNCAN C. L. FITZWILLIAMS, F.R.C.S., &c. Surgeon to St. Mary's Hospital. London: Humphrey Milford, Oxford University Press. 1927. Pp. 505. 36*s*.

IN this monograph Mr. Duncan Fitzwilliams has given a comprehensive account of the diseases of the tongue as viewed from the standpoint of modern surgery. In compiling it he has drawn upon the accumulated records of the past, and has supplemented these by the experience gained by himself and his colleagues at St. Mary's Hospital. The references given at the end of each chapter are evidence of the author's industry in the ransacking of "authorities" the definite views which he expresses upon questions such as the treatment of carcinoma of the tongue show that he has thought and practised to some purpose. The result might have been a text-book

of outstanding value, but is, in fact, disappointing. Not that anything of importance has been omitted. The author's thoroughness has indeed led him into giving a detailed account of the surgery of salivary calculi, a subject which is really outside the scope of a treatise on the tongue. The book suffers throughout, however, from a diffuseness and lack of discrimination which tend to blur the outlines of the picture. Its pages are enlivened by many anecdotes; no one could fail to be amused by the story of the policeman's wife who avulsed her own tongue; but the reader is wearied by a multiplication of case-histories with unnecessary details, which might with advantage have been condensed and pruned, and a volume of over 500 pages reduced to one of 300 pages, without loss to the reader. The author's style is conversational and often ungrammatical, faults which also tend to obscure the value of the book. The same lack of discrimination somewhat spoils the impression made by the very numerous illustrations; many are of excellent quality, but others are so imperfectly drawn or reproduced that they had better have been omitted. The book, in fact, though containing much valuable material, lacks the distinction of many of the other volumes issued in the same series of publications.

INTESTINAL TUBERCULOSIS.

By L. BROWN, M.D., and H. L. SAMPSON, Trudeau Sanatorium, New York. London: Baillière, Tindall and Cox. Pp. 304. 18*s*.

IN this book the reader will find a very complete account of intestinal tuberculosis. The authors set out fully their reasons for considering this to be the most frequent complication of pulmonary tuberculosis; since from 50–80 per cent. of all autopsies on patients dying of phthisis disclose intestinal tuberculosis its high incidence is apparent. Little importance, in the opinion of the authors, can be attached to the discovery of tubercle bacilli in stools, since they occur in about 90 per cent. of all patients who have tubercle bacilli in the sputum. Digestive disturbances, on the other hand, are significant; marked constipation, increase of indigestion, and continued pyrexia with simultaneous diminution in the pulmonary signs should, the authors expressly say, always arouse suspicion of intestinal complications, whilst hypermotility of the alimentary canal, with nearly complete emptying of the colon in 24 hours, or constant segmentation with or without dilatation of some coils of the normal intestine, are amongst the most important X ray findings in cases of intestinal ulceration. As regards treatment, the authors consider that heliotherapy and exposure to ultra-violet rays are often extremely useful. The book will be read with interest by those engaged in the treatment of tuberculosis.

TOWARDS HEALTH.

By J. ARTHUR THOMSON, M.A., LL.D., Regius Professor of Natural History in the University of Aberdeen. London: Methuen and Co., Ltd. 1927. Pp. 242. 7*s*. 6*d*.

Prof. Arthur Thomson's writings have been always clearly written and sanely conceived, and his latest book will not disappoint his readers. He approaches health from the standpoint of the pure biologist, and is thus able to stimulate enthusiasm about health without laying too much stress on the way to avoid disease. He bases his biological outlook on the trilogy: organism, function, environment. The first two chapters are concerned with the analysis of life by this "biological prism." In chapter three he deals with heredity, stressing particularly the importance of nurture as opposed to nature, and he holds the balance very ably between the extremes of the inheritance and the environmental schools. The next sections in which sex and birth control are dealt with on biological lines are excellent, and offer a pleasing contrast to many of the popular writings on these matters. After a chapter on the healthy mind, packed full of common sense and sound psychology, the practical applications of biology are discussed in a chapter headed "What can be done?" Prof. Thomson's suggestions are by no means revolutionary, and have a scientific basis. Because it is so good certain small errors should be corrected in the next edition. Lister introduced antiseptic, not aseptic, methods of modern surgery (p. 23), vitamin C is not concerned with rickets, as is suggested (p. 57), and, since the Huntingdon type is so rare, it is misleading to say that some forms of St. Vitus's dance are inherited (p. 72).

We would commend a study of this book to the great statesman mentioned on p. 200, who summoned an eminent man of science and asked what should be done to secure an A1 physically fit society, for Prof. Thomson's book is full of constructive suggestions.

CONTRACEPTION.

Its Theory, History, and Practice. Second edition. By MARIE CARMICHAEL STOPES, D.Sc., Ph.D. London: John Bale, Sons and Danielsson, Ltd. 1927. Pp. 480. 15*s*.

THE second edition of this book, the title page informs us, appears on the completion of the sale of 40,000 copies of the first edition, published in June, 1923. The new edition contains some 60 pages of fresh matter. More, it represents the fruit of much practical experience. Since its foundation in March, 1921, there have passed through Mrs. Stopes's clinic in Holloway over 8000 women—a number surely large enough to satisfy the statistical demands of the most exacting inquiries.

In this book are described certain modifications of contraceptive technique which have been found helpful. Chinosol (described as a disinfectant; its chemical composition is not given) is now used in place of quinine, in a cocoa-butter suppository, as a routine at the author's clinic, in addition to the all-rubber occlusion cervical cap. Mrs. Stopes deduces from certain observations she has made that a process of "interlocking" takes place during coitus with women with a patent os. The question is of importance since, if it takes place, it necessarily follows that a reliable contraceptive technique cannot be evolved from a chemically spermicidal principle alone.

Like the first, this edition contains a very well documented history of the theory and practice of contraception, to which the author has clearly devoted much time. Much that is contained in these chapters is original. There is a chapter on contraception and the law, and another upon instruction in contraception in medical schools which might be read with profit by many medical men. This edition amplifies and consolidates the status achieved by the first.

JOURNALS.

BRITISH JOURNAL OF CHILDREN'S DISEASES, Vol. XXIV. July–September.—Dr. Matthew Young and Mr. W. T. Russell contribute a paper on Sexual Differentiation in Susceptibility to and Mortality from Whooping-cough in Children under 5 Years, their conclusions being as follows: The mortality from whooping-cough computed from the deaths registered as due to this cause is generally sensibly higher in females than in males under 5 years. This sexual differentiation in mortality from whooping-cough and its complications becomes more intensive as age at death increases from 1 to 5 years. The statistics of cases notified in Glasgow and Aberdeen confirm the impression based on hospital admissions that female children are more susceptible to the disease than male children. The only feasible explanation of this sexual differentiation in mortality seems to be that infection with the whooping-cough germ, though seldom fatal in itself, has apparently the ability to modify in an unequal degree the powers of resistance of male and female children, rendering females more vulnerable than males to intercurrent respiratory infections and

their sequelæ. An analogy can be found in certain other diseases, such as chorea and goitre, which occur at a later period of life, and appear to affect the female sex more frequently and with a greater fatality than the male.—In the first part of a paper on the Insulin Treatment of Diabetes Mellitus in Children Dr. K. U. Toverud, of Oslo, discusses the frequency of diabetes mellitus in children in Norway and records his observations on four years' insulin treatment in children aged from 1½ to 14 years, showing the effect of the treatment on the physical and mental development of the child, with remarks on the technique of insulin administration and the reaction to the drug.—In Part II. of their paper on Hemiplegia Associated with Extensive Nervous and Mental Defect, Dr. T. Brushfield and Dr. W. Wyatt report two more examples of this syndrome and allude to three similar cases, apparently the only ones on record, published by E. A. Cockayne, F. Parkes Weber, and D. M. Greig respectively.—A paper follows by the late Dr. Edith Bronson on Functional Cardiac Disorders: Symptoms, Signs, and Treatment.—In a paper on Some Practical Points in the Treatment of Ringworm with Thallium based on his observations at the Skin Department of the Royal Alexandra Hospital for Sick Children, Brighton, Dr. J. H. Twiston Davies describes the technique of this method together with some practical points relating to the pharmacology of thallium.—The abstracts from current literature are devoted to genito-urinary diseases.

BRITISH MEDICAL ASSOCIATION.

ANNUAL DINNER.

THE sixth annual Council dinner of the Association was held at the Hotel Victoria, on Wednesday, Oct. 12th, under the chairmansh p of Dr. H. B. BRACKENBURY, when a large company was present.

When the loyal toast had been honoured, the Chairman proposed the health of the Retiring Officers. Mr. R. G. HOGARTH (immediate past president) paid tribute in reply to the loyalty and wisdom with which he had been supported in his year of office by his associates. Sir ROBERT BOLAM, the retiring chairman of the Council, also speaking in reply, welcomed the two Ministers of the Crown who were present as evidence of official confidence in the Association.

The Toast of the Common Health.

Mr. H. S. SOUTTAR, in proposing the Common Health, remarked on the wide interest now taken by the public in the health of the nation, and said that the medical profession had played its part in the improvement of health well but in an incoördinate way which made us the despair of other nations. The hospitals, originally a refuge for the sick poor, had become great machine shops for the cure of those who were ill, with a wonderful organisation for following up discharged patients. In themselves they were coördinated, but they were isolated, and had as little connexion with the great body of general practitioners and with the municipal and State hospitals as if the latter did not exist. Surely much could be done by coördinating all three services. That, it seemed, was where a Ministry of Health came in. He envisaged the hospital in which he worked as the centre of a great medical service, embracing all practitioners. This would not be an infraction of the voluntary principle. There was, moreover, an important distinction between a State medical service and medicine in the service of the State; the former might be somewhat un-English, the latter was thoroughly British. Service of the State was much greater than service of the profession, and we need not shrink from it.

The Minister of Health's Reply.

Mr. NEVILLE CHAMBERLAIN, in reply, outlined the parts which his department and the profession played respectively in working for "the common health." Doctors repaired the damage done by heredity environment, and the ignorance and folly of their patients; the Ministry's part was to surround the individual with such signposts, safeguards, and wire entanglements as would leave the profession as little to do as possible. There could be no better evidence than the fall in the adult and infant mortality-rates to prove that both sides were making a good job of their work. Some credit could be claimed for the activities of the Ministry, especially in its attack on tuberculosis and its maternity and child welfare work. One of the most potent factors had been the education of the men and women of the country in the means of keeping healthy, an education fostered by general practitioners, medical officers of health school medical officers, and—with perhaps at times some bewilderment to the public—by the press. He hoped that the new powers given to the Ministry would result in an extension of this work, to the confusion of mischievous fanatics such as those who were responsible for the rapid spread of small-pox. Education, moreover, was needed by practitioners. It was no wonder that, working for years far from the centres of knowledge, they were apt to miss the early signs of diseases such as tuberculosis, the treatment of which had cost the nation last year £2,500,000. He was deeply interested in the post-graduate medical school which it was proposed to establish at the West London Hospital. General practitioners, besides learning there, might have something to teach those working on education or research. Although the housing problem was by no means solved, new accommodation had been provided for 1,000,000 persons in the last 12 months, thus opening up a path to an attack on the slum problem. This was not only a problem of clearance; in 1925 500 times as many houses had been repaired and reconditioned by local authorities as had been demolished under clearance procedure. Other activities of the Ministry, continued Mr. Chamberlain, had been the provision of cleaner milk, purer food, and a less smoky atmosphere, and he hoped to see added to the Statute Book before Christmas the Nursing Homes Registration and Mental Deficiency Bills. Further in the future lay legislation on the slum problem and on lunacy, with especial reference to the protection of the certifying doctor. He would like to see a system of specialist services in connexion with National Health Insurance and, above all, the reform of the Poor-law. Unless better coöperation could be secured he feared for the voluntary system, the loss of which would be a disaster, and one of the most effective steps in coöperation would be the conversion of Poor-law infirmaries into municipal hospitals. Without some measure of this sort he saw no hope of realising the ideal, namely, hospital treatment for every citizen in the country. He spoke warmly of the good relationship that existed between the Association and the Ministry and appealed for their confidence and support.

The Guests.

Dr. R. W. LESLIE, in proposing the Guests, alluded to the future of the medical profession in India and congratulated the Indian Medical Service on having so capable a hand as that of Lord Birkenhead on the reins. He deplored the condition of medical charities.

Lord BIRKENHEAD spoke of the advantages of a medical career in India for young and adventurous scientific men.

Dr. RAYMOND CRAWFURD, who also replied, emphasised the lamentable state of medical charities and reminded the company that one guinea per annum from every medical practitioner would solve the whole problem.

The health of the Chairman was informally proposed by Sir EWAN MACLEAN (the president-elect of the Association), and after Dr. BRACKENBURY had replied the proceedings closed with the singing of Auld Lang Syne.

THE LANCET.

LONDON: SATURDAY, OCTOBER 22, 1927.

ENCEPHALITIS LETHARGICA TO-DAY.

It is now about ten years since encephalitis ethargica made its appearance in England. The arly cases were chiefly characterised by prolonged leep, and the physicians who watched these first atients spending days or weeks in peaceful slumber, r (as often happened) passing through slumber to n easy death, could little realise the unspeakable ruelty of the curse that had come upon us. Now, fter ten years, we are in some position to take its easure. Every succeeding year has seen its epidemic; he acute phase of the disease has quickly grown ilder, so that severe cases are seldom met with, nd often the invasion is so mild that the patient s unaware of any illness. But now we know that the ightfulness of the scourge lies in its after-effects, hat few patients in whom the acute infection has een recognised entirely escape undamaged, and hat even those in whom this phase has been nrecognisable, or in whom it may not have existed t all, may suffer severely as a result of the infection. ymptoms may persist without intermission from he acute illness or may develop weeks or months r years after the patient has seemed to make a good ecovery; though the interval is generally less than 2 months, a Parkinsonian syndrome has been nown to develop as long as five years after the iginal attack.

It is only natural, since the brain controls many nctions, that the consequences of its derangement ould be very various, and in fact the different inical pictures presented after encephalitis are almost numerable. The great majority of cases, however, ll into one of three groups in which the principal mptoms are respectively motor, mental, or respira- ry. The first of these groups is undoubtedly the rgest; in the second, with mental symptoms, ost of the patients are children and adolescents; e third is much smaller than the other two, but spiratory tics following encephalitis are becoming dely recognised and are now mentioned in almost ery report. Common to nearly all the cases—o whatever group the other symptoms may fall—is disturbance of the rhythm of sleep. At night these tients, especially the children, become more awake d lively and mischievous, sometimes excited, metimes frightened. This is one of the few sym- oms which has a definite tendency to recover and, diurnal sleep is prevented it seldom continues re than 12 months. The motor manifestations nstitute the now familiar Parkinsonian syndrome, d some signs of this syndrome, however slight, e presented in nearly every case. They resemble st nearly the picture of paralysis agitans, except t there is little or no tremor. The general ture from which the more obvious symptoms se is a rigidity or hypertonus of all the muscles, d at the same time there is loss of automatic or ergic movements. The result is general stiffness the body, slowness of movements, and a mask- a, staring expression. In many patients nothing re than a fixity of the facial expression is to be served; in others, at the opposite extreme, the iculty of movement may become so great that they are unable to feed or dress themselves, and can hardly chew their food. Owing to the stiffness of the muscles of the face and jaw the mouth is habitually held open, and excessive salivation causes a dribbling which is sometimes felt as one of the greatest burdens. As in the true Parkinson's disease there may be a loss of equilibrium, a tendency to run forwards or backwards, or, when sitting, to let the body sink slowly forwards or sideways till the head is on the level of the seat of the chair. As a rule, there is no injury of the pyramidal system, but hemiplegia or even bilateral pyramidal disease may be present in association with Parkinsonian symptoms.

The mental changes, as has been said, occur chiefly in children and adolescents, though they are by no means unknown in adults. The intelligence is seldom affected; nearly always the alterations are in the sphere of moral control and sometimes emotional disturbances may be added. The children, clean and docile before the attack, begin to use bad language, lie, thieve, masturbate, and be cruel to other children; at the same time they may be irritable and have outbursts of weeping or demonstrative affection. Many of them find their way to the police-court, and thence to the indicated asylum. Lastly, the respiratory tics are among the most curious of the many symptoms that encephalitis has made known to us. Probably the commonest consists in periods of tachypnœa. In a recent report to the Metropolitan Asylums Board Dr. G. A. BORTHWICK, of the Northern Infectious Diseases Hospital, mentions that visitors to the post-encephalitic unit are at once struck by the sound of heavy panting as if many of the patients had just been running a race. The attack may last from two or three minutes to many hours, and cases have been recorded in which the hyperpnœa induced tetany. Hyperpnœa may be followed by a short spell of apnœa, as in Cheyne-Stokes breathing. There may also be sighing, yawning, coughing, and other noisy expiration. These may be accompanied by more or less rhythmic movements of the arms or trunk and sometimes the patient is in great distress.

Treatment of the after-effects of encephalitis has not been at all successful as regards cure, though something may be done to ameliorate the sufferers' condition. Hyoscine and belladonna, combined with massage, help to reduce the rigidity and salivation of the Parkinsonian state. Acting on the view, now gaining ground, that there is often residual infection of the brain after the acute attack, or that the infection may be chronic from the beginning, several workers have tried the effect of malarial treatment. The hope is that malaria or its effects may overcome the infection and cause the symptoms to pass away; the extent to which this hope is realised may perhaps be estimated from the results contributed to our present issue by Dr. ROY CRAIG and by Drs. P. K. MCCOWAN and L. C. COOK. Failing more efficient means of treatment we can only look to epidemiologists to find more efficient means of prevention.

THE FIRST-BORN.

THE peculiar position which the eldest son occupies in the English family by law and convention is generally attributed to the greater probability that his younger brothers have not the same authentic origin. Its advantage to the community may be doubted in view of Prof. KARL PEARSON'S discovery that first-born children enter on their fight with the world under some handicap in body and mind; but on the other hand this discovery does not neces-

sarily imply a willingness on the part of society to be led by weaklings, for it is arguable that the possession of family state or title is an obstacle, rather than otherwise, to holding positions of great responsibility. It is worth considering, perhaps, whether the queer local variant of the "Borough English" custom which put the youngest in the seat of the eldest did not have its beginning in some practical unsentimental idea that the boy to carry on the family should be as little as possible defective in any way. Whatever the truth of these theories may be the facts themselves are extraordinarily interesting, and Prof. G. F. STILL'S Ingleby lectures, the first of which we published last week and the second of which appears this week, will, we are sure, stimulate many readers to look further into the whole question.

Prof. STILL concludes that there is definite evidence that congenital hypertrophy of the pylorus is much commoner in first-born than in later children, and that congenital heart disease, other congenital abnormalities, mental deficiency, and probably epilepsy have the same relation to order-in-family. The validity of these conclusions depends, of course, on the method by which they have been reached, and we would direct particular attention to the ingenious way in which Prof. STILL has met the very considerable difficulties of the inquiry. He rightly insists that first-in-family must mean the first pregnancy, not the first live child. There are no official mass statistics of miscarriages and until recently none of stillbirths; reliance can, therefore, be placed only on individual data which have been personally collected from parents, and he does not minimise the facts that many early pregnancies are not identified and recorded as such, and that women are apt to forget conceptions that did not result in some tangible product. The data are thus open to some criticism, though it is difficult to see how they could be bettered. Seeking to establish the proportion of those who are first-born by this criterion in an average normal population, he brings out plainly what is so often overlooked in medical statistics—that the clientele of hospital and private practice are a class selected by a variety of considerations and are by no means necessarily representative, quite apart from their illness of the moment, of the population as a whole. Nearly one-half of 1000 consecutive children seen by him in private practice were first-born; such mass statistics as are available show that only about one-fifth of live children fall in this group. It is fairly obvious that the difference might be due to maternal anxiety and inexperience, quite apart from any differential incidence of disease. A fair sample of the general population from which his patients are derived seems to be unobtainable except with the aid of a battalion of home visitors who would accumulate the obstetric histories of hundreds of women who at the moment were not interested in sick children; their curiosity might be rewarded or it might not. The results at any rate are not available at present. For them Prof. STILL substitutes the distribution of place-in-family in 900 cases of pneumonia, judging on a priori grounds that the number of instances of such a disease for which medical aid is sought will be determined by necessity rather than choice, and that it is a disease which is very unlikely to have any relation to the order of pregnancies. From this he derives a standard curve which shows about 20 per cent. of children as first-borns. But of 400 cases of congenital hypertrophy of the pylorus, some 48 per cent. are first-born, while 500 instances of tuberculosis and 1000 of digestive troubles are distributed among the place-in-family groups in almost exact correspondence with the standard curve. It seems fairly clear that eldest children are particularly prone to pyloric hypertrophy; if there is some fallacy in the statistics and they are not, it would appear to follow that first-borns are *less* liable to pneumonia, tuberculosis, and alimentary disorders; in either case place-in-family is a factor in determining the incidence of disease, and if that fact has been definitely established for any one disorder there is every encouragement for others to pursue the topic as he has done.

Experience counts for much. SAMUEL BUTLER thought that accumulated experience was the basis and method of evolution, and even those who are not prepared to join him in such heresies will admit its efficacy in the life of an individual. Repeated trials and practice will improve the capacity of the body to do anything—from playing golf and bridge to the production of antibodies and the regeneration of red corpuscles. The same must surely be true of conception and pregnancy. A first child is liable to have rather a rough passage into the world because of his mother's inexperience, and for the same reason often has much too smooth a voyage afterwards. Practice will improve his mother's dexterity in parturition and discipline, and it requires no great imagination to believe that the skill of her tissues in the delicate intricacies of fertilisation and early pregnancy will also increase with trials.

THE HOSPITAL POSITION IN SCOTLAND.

THE hospital position in Scotland is entering an acute phase. Last year Lord MACKENZIE'S Committee on Hospital Services reported that there was a shortage of some 3000 hospital beds in the country, and the accompanying recommendations of the Committee formed an attempt to formulate a policy for Scotland which should preserve and develop the voluntary hospitals, while securing, by intimate and friendly coöperation, a continuously adequate hospital service. This would imply joint effort on the part of the voluntary hospitals and the local authorities, and the removal of the poor-law stigma from all institutions, the transfer of powers to the local authorities being designed to introduce that policy of "all-round coöperation" which now represents the predominant view in Scotland. At the recent meeting of the Scottish Regional Committee of the British Hospitals Association in Glasgow, the speakers were, practically without exception, in favour of this policy; Colonel D. J. MACKINTOSH, superintendent of the Glasgow Western Infirmary, in an admirable discourse, made it plain that the future of the voluntary hospitals depended on their coöperation with one another and with the statutory bodies. In Glasgow already there is a certain amount of coöperation of the kind wanted, but it was agreed by the meeting to send a deputation to the Secretary of State for Scotland, with the view of getting a definite lead on the Government's hospitals policy. But quite apart from questions of possible State subsidy to make good the shortage of beds which will thus be raised, the representatives both of the local authorities and of the voluntary hospitals hold strongly that a scheme of readjustment is necessary.

Meanwhile, at Aberdeen, Sir JOHN GILMOUR, Secretary of State for Scotland, has presided at the formal opening of the Woodend Hospital, when the parish council handed over the keys to the town council. This marks an important stage in the development of a great hospital scheme for Aberdeen. As the Secretary of State explained, there are four bodies materially involved—the University through its medical school, the Royal Infirmary as the great medical and surgical hospital, the municipality in charge of the City Hospital for Infectious Diseases

and the parish council as in charge of the poor-law hospitals; and the problem was to readjust the management of the institutions so as to honour in full all the interests involved. The poor-law hospital was not sufficiently equipped to justify the Scottish General Nursing Council in recognising it as a training school for nurses. This parish hospital was erected less than 30 years ago, and a "special" hospital has been erected more recently. But this "special" hospital of 180 beds stood vacant, giving an opportunity for negotiations, while the City Hospital for Infectious Diseases badly needed extension both for cases and for staff, while a vacant hospital stood ready for their use. A proposal was made that the municipality should not merely use the special hospital for municipal cases, but should also take over the medical work for the parish council, and an agreement was arrived at that the municipality should be responsible for the medical and surgical treatment on modern lines of all poor-law cases requiring treatment, including cases from the county parishes of Aberdeen as well as from the city. The city also adapted the special hospital to its own requirements.

Further proposals were made for the extension of the City Hospital itself, an extension long overdue; but for this and the other developments the sanction of the Scottish Board of Health was required. Before giving sanction, however, the Secretary of State, as President of the Board, would have to be satisfied that other interests concerned—namely, those of the University medical school and the Royal Infirmary—were not placed under any disadvantage. Therefore, the condition had been made that the clinical professors of the University should have full facilities for teaching both in the City Hospital and in the new Woodend Hospital. The full significance of the opening of the Woodend Hospital by the Secretary of State thus appears. Under his sanction these two institutions, invloving ultimately perhaps 700 beds or more, should be available in the fullest sense for the work of the medical school and the care of the appropriate cases. And this does not complete the story of hospital development in Aberdeen. For a new Sick Children's Hospital on the Forresterhill site is rising, and, with the financial assistance of the city, a new Maternity Hospital is to be provided in the same campus, where there is already a Maternity Home. Agreements, also, have been concluded whereby the University and the Royal Infirmary acquire from the municipality a sufficient portion of the same area for a new Royal Infirmary. Research and teaching departments of the University will be placed here, and a sanatorium for tuberculosis is projected. Thus, on the one campus, the University student will have easy access to a series of primary institutions, and by the arrangements now completed the new Woodend Hospital and the City Hospital, though a considerable distance from Forresterhill, will become integral elements in the total scheme. And the same general group of consultant and visiting physicians and surgeons will be in a position to adjust their particular services to the conditions of the patients.

The problems at Aberdeen have arisen out of the city's own peculiar difficulties, but the course that is being taken is of wide and general significance. Here, at a single stroke, the municipality assumes and arranges for a complete hospital service for all sick persons entitled to treatment at the hands of the statutory bodies, and, at the same time, the voluntary hospitals are not merely preserved in their autonomy but are materially assisted in their working resources. The main obstacle to the realisation of the great scheme as a whole has been the cost of a new Royal Infirmary, and this is in fair way to be removed. The Lord Provost of Aberdeen, Mr. ANDREW LEWIS, has asked the public for £400,000 to build and partially endow a new Infirmary, and has already obtained over £253,000 towards that sum. Feeling confident of obtaining the amount asked for, he has set the final negotiations on foot for the acquisition of a sufficient site, and the plans for the new Royal Infirmary are in preparation. Lord Provost LEWIS has thus brought about the present position whereby this satisfactory combination of poor-law and municipal hospitals has been effected, and has also succeeded in pushing forward on a large scale the design of the Voluntary Hospitals Commission. His achievement proves that there is in the end no real antagonism between the voluntary system and the official system. It proves further that, by judicious and friendly coöperation, the common hospital services will now become more adequate, and the incalculable value of the voluntary system will be more fully realised. No doubt the City of Aberdeen is in a very fortunate position; because, from time immemorial, the City Authorities and the University have worked together in the most intimate way. When, over 30 years ago, the modern extensions of Marischal College were planned, the pessimists declared that the scheme was Utopian. Yet when KING EDWARD VII came to open the new buildings, scepticism had long vanished. It will be the same when the joint hospital scheme is completed. What Aberdeen has done, other cities, in their own special way, can also do. From the friendly attitude of the British Hospitals Association, it seems probable that we shall not have to wait long for similar developments.

Annotations.

"Ne quid nimis."

THE ASSOCIATES OF HARVEY AND HUNTER.

DURING the past week two of the really great men of medicine have been officially commemorated. On Monday, at the Hunterian Society, Mr. A. E. Mortimer Woolf devoted his second presidential address to Some Personalities of the Hunterian Epoch, the bicentenary of John Hunter's birth falling during his term of office. On Tuesday, at the Royal College of Physicians of London, Sir William Hale-White delivered the Harveian oration—printed in another column of our present issue—taking as his title Gilbert, Bacon, and Harvey. Foundations for the annual commemoration of any one man, however distinguished, are hampered by the fact that there must come a time when it is difficult, if not impossible, for the orator to say anything new about the man whom it is desired to commemorate. For this reason Sir William Hale-White chose rather to look among Harvey's contemporaries in order to see who were the men around him who might especially have influenced his life and work. Harvey was, of course, Francis Bacon's own physician, and a book which became so immediately popular as did the "Advancement of Learning" must have been familiar to him. In this book Bacon pleads for the experimental method and for the appropriate reward of experimenters, whom he describes as the "spials and intelligencers of Nature," and although a strict comparison of dates may suggest that Harvey could owe nothing to the "Novum Organum," yet it is reasonable to suppose that Bacon, who made no secret about his philosophical work, talked about it with his physician as he did with his chaplain, so that his teaching can hardly have failed to touch the mind of Harvey. In London as it then was, no bigger than a large provincial town, the two must have seen much of each other; Bacon with his chronic introspective dyspepsia must have consulted his physician frequently; there may be no evidence that Bacon attended Harvey's Lumleian lectures, but Harvey's writings bear the impress of scientific deduction, the counterpart of that of the philosopher. Sir William Hale-White will, we think, persuade his readers even if, as he admits, the evidence is circumstantial rather than direct; "how little," he remarks, "we know of the daily doings of people who lived 300 years ago."

This is true of the Hunterian epoch, for apart from the results of their scientific labours it is remarkable

how little we know of the personalities of the Hunters or of their contemporaries—William Cullen, William Smellie, Joseph Black, Gilbert Blane, William Clift, and the others to whom Mr. Woolf refers in his address. He naturally gives pride of place to John Hunter's illustrious brother William, to whom John owed a debt of gratitude which most regrettably he forgot in after life. Of William Hunter we know that he was physician to Queen Charlotte, but he had another patient in a more humble walk of life, whose child is better known to many than the sovereign in question. On the evening of June 23rd, 1766, Mrs. Smith was returning in a hackney coach from the house of her brother in Seven Dials to her own house in Great Portland-street, and while still in the coach gave birth to John Thomas Smith, author and antiquary, whose "Book for a Rainy Day" and "Nollekens and His Times" could ill be spared. Mr. Woolf believes that during Hunter's time witchcraft had a great influence on medical treatment. However that may be, quackery, of course, was still rampant and even the medical profession was not exempt from belief in quack remedies. A notable example he gives is that of Joanna Stevens, who contrived, with the aid of various titled persons, and armed with testimonials from Cheselden, Cæsar Hawkins, and Samuel Sharpe, who had been Cheselden's apprentice, to get £5000 out of the Government for the recipe of her remedy for the stone. Mr. Woolf mentions another quack, Taylor the oculist, who dubbed himself Chevalier, and numbered among his patients the infant Gibbon. Johnson and Walpole both took him at his proper valuation. The latter, in a letter to Mann, dated June 9th, 1755, thus refers to him: "I need not desire you not to believe the stories of such a mountebank as Taylor. I only wonder that he should think the names of our family a recommendation at Rome; we are not conscious of any such merit; nor have any of our eyes ever wanted to be put out." Mr. Woolf discoursed pleasantly about other medical men of the time—Abernethy, Hewson, and the shameless Jesse Foot; he tells the story of Sir William Blizard attending in full court dress to receive bodies from the hangman, although we believe he is not right in locating the College of Surgeons itself in Cock-lane—the College had hired a house in that street for the purpose of official dissections, the place being convenient for Newgate. Last and by no means least of those mentioned by Mr. Woolf is William Clift, the unwearied curator of the Hunterian Museum. Clift died in 1849, but many years earlier he nearly met with the fate of Jonah. A whale had been captured off the Nore and the carcass beached on the Isle of Dogs. Clift, always on the alert for any specimens of anatomy, went down to see it. He stepped inside the mouth which was propped open and immediately slipped on the oily decomposing tongue towards the gullet. From this perilous situation he was rescued by a boat-hook. Mr. Woolf is to be thanked for his informing and amusing address.

THE PNEUMOCOCCUS IN LOBAR PNEUMONIA.

THE investigations of the Rockefeller Institute have shown that there are three dominant types of pneumococcus each possessing a specific immunity reaction. They are called Types I., II., and III., whilst all other types, including many as distinct as the first three, are grouped together and referred to collectively as Type IV. Types III. and IV. are often found in the mouths of healthy people, but the others never. An attempt has now been made by R. L. Cecil, H. S. Baldwin, and N. P. Larsen[1] to correlate the type of pneumococcus with the clinical manifestations, complications, and other features of the disease. Two thousand cases of lobar pneumonia were examined bacteriologically and clinically, and 1913 were due to the pneumococcus. In classifying these preference was always given to the pneumococcus as the causative organism if the infection was mixed. The type was usually determined by examination of the sputum or pharyngeal swabs, sometimes by blood culture, and in fatal cases by lung puncture after death. Inoculation of mice was used exclusively for further investigation of serum reactions. It was found in the series that 34 per cent. were of Type I., 19 per cent. of Type II., 13 per cent. of Type III., and 33 per cent. of Type IV. Types II. and III. were the most fatal, each with death-rates of 42 per cent.; Types I. and IV. were milder, with death-rates of 21 and 29 per cent. respectively. The authors point out, however, that these figures alone cannot be taken as an estimate of virulence, for the age-incidence of the various types is probably a factor of at least equal importance in prognosis. This is confirmed by the observation that young people are particularly prone to Type I. infection and the elderly to Type III.; yet when Type III. does occur under 30 it is not a severe infection. In 329 patients a blood culture was taken and it was found that among 240 whose blood was sterile the death-rate was 19 per cent., whilst among 89 positives it was 83 per cent. In Types II., III. and IV. a positive culture indicated a fatal termination in 90 per cent. of cases, but in Type I. the prognosis was less grave. These figures, it is pointed out, are open to a serious criticism on the ground that in many cases only one or two cultures were taken. It is not stated at what stage in the disease or in what particular type of case blood culture was attempted. The mortality was found to increase with the number of lobes involved, but this seemed not to depend on the type of pneumococcus. The incidence of severe complications was very much higher with Type I. infection, but here again the tendency of children to be affected rather than the type itself may have been the chief factor. This analysis of a large number of cases gives a clear idea of what the physician gains by finding out the type of pneumococcus with which he is dealing. Apart from the possibility of employing serum treatment, if the organism happens to be of Type I. this knowledge does not appear to be of great use in the individual case, the features of the type being obscured by such factors as age, extent of pulmonary involvement, and coexisting disease. A positive blood culture seems to be of more value in prognosis, but a single negative result is not to be relied on, whilst repeated examinations do not seem advisable in a patient who is very ill with lobar pneumonia.

[1] Arch. of Intern. Med., September, 1927.

THE USE AND ABUSE OF ENEMAS.

Dr. L. J. Hirschman in a recent paper[1] points out that it is a pity to obscure the uses of properly administered enemas by too much enthusiasm. They may be used legitimately for cleansing purposes, for rectal feeding and the administration of drugs, for the relief of abdominal distension, and for the direct application of antiseptics and astringents to the mucous membrane in bacterial infections. They may also be employed to lower or raise the temperature of the body, whilst opaque enemas are essential in radiographic examination of the lower bowel. He considers that flushing out the colon by gallons of water has been done too much in recent years. A large quantity of water, he says, not only distends the bowel, but causes hyperæmia and removes the mucus which is the normal intestinal lubricant; regular and too frequent irrigation also irritates the mucous membrane and robs the muscle of the bowel of the solid material which is necessary to maintain its tone. Constipation, in his view, can never be cured by colon irrigation alone, and in many cases in which X ray examination shows evidence of adhesions the method should never be tried. Soap is as irritating to the mucous membrane of the bowel as to the conjunctiva, and should not be given in enemas as it produces an angry red appearance of the mucous membrane which is often mistaken for proctitis; Dr. Hirschman prefers 1 per cent. sodium bicarbonate as a routine. The type of tube used is important, and it should never have a hard rubber or glass nozzle as this is liable to cause injury. The best

[1] Jour. of Amer. Med. Assoc., Sept. 24th.

ube for insertion is a soft rubber urinary catheter 20–24 French scale) with a conical top beyond the perture, and this can be connected to the ordinary nema top. The lubricant should be water-soluble nd is best made of gum tragacanth or Iceland moss. Hycerine should never be used if there is any reason o suspect a raw surface. Olive oil makes subsequent leaning for operation more difficult. The lateral osition is the most convenient posture, he says, for dministering the enema, as the parts can be seen and he weight of the abdominal viscera is away from the owel, so that there is no obstruction to the entrance f the fluid. Opaque enemas have shown that one int of fluid will pass to the cæcum in one minute, and is unnecessary and generally impossible to pass a ectal tube into the sigmoid without using a sigmoidoscope. When fæces are hard or impacted one part of ydrogen peroxide to two of warm water may be sed to disintegrate them, and for the expulsion of atus a 6 per cent. solution of powdered alum is more ffective than turpentine. Dr. Hirschman ends his eries of comments by pointing out that there is o reason to include starch or milk in the nutrient nema, though glucose, as is now generally recognised, ıay usefully be given.

THE PROVISION OF DENTAL CLINICS.

THE fifteenth annual report of the British Dental ospital shows that this beneficent institution is now esponsible for equipping and maintaining four treatıent centres, 12 maternity, child welfare, and ıberculosis dental clinics, and one minor ailment entre. Its object has always been to work in conınction with borough councils, the hospital providing cilities and skilled treatment while the municipalities ovide a sum towards upkeep. In many respects ıis is an ideal arrangement, and it is not surprising ıat an increasing number of councils are taking lvantage of it. The scheme makes for efficiency ecause it does away with all possibility of unwise terference by the laity in professional matters, and ısures that the staff of dental surgeons are chosen r reasons of professional skill, being elected by embers of their own profession who manage the spital. This eliminates the chance of wire-pulling metimes associated with appointments in the hands local political bodies.

There is much concern in the dental profession at e present time over the demand of the approved cieties that dental clinics shall be established to eat insured persons, for there is some reason to ır that these clinics, being largely controlled by the cieties or their nominees, may put economy (at the pense of the dentist) before the real interest of the tients. The British Dental Hospital points out e way in which clinics could be established which uld give the best possible treatment to insured tients and yet allow perfect freedom for the staff purely professional matters. Although established provide treatment for those unable to afford dinary fees, it is not a purely charitable institution e the voluntary hospitals; fees are charged, ough they are modest, and on the whole the instition is self-supporting. Besides offering dental atment it has always aimed at educating the blic in oral hygiene and at assisting public bodies the provision of dental facilities, and useful work both directions is being carried out.

It is probable that few medical men are aware of e extent of the various dental clinics in existence in s country. The school clinics controlled by the ndon County Council and other public bodies are miliar to all, though the immense scope of their rk is imperfectly known. But in addition to these re are dental clinics for tuberculous patients d in connexion with maternity and child welfare ntres, and in the aggregate the amount of treatment ried out by means of public funds is very considere, though still pitifully inadequate to the needs the community. It is certain that the future will a wide extension of public dental service in ny directions. In the treatment of tuberculosis, for instance, care of the teeth is often an essential, both as regards the removal of septic foci and the provision of artificial teeth for purposes of mastication. In antenatal clinics the need is equally urgent. It has been suggested that dental sepsis may be a factor in the occurrence of puerperal sepsis, whilst H. Waller has shown that maternal sepsis affects the suckling infant. The occurrence of widespread dental disease in young children makes the provision of dental clinics for the pre-school period another urgent necessity. It is refreshing to read this account of an institution which has accomplished so much useful work without any generous assistance from the public.

RESEARCH ON HEREDITY.

THE hygienic era in which privies and albuminoid ammonia dominated the field has been replaced by one where bacteriologists have had as much influence as they deserve. The next phase of preventive medicine will presumably be mainly concerned with the heritable constitution of individuals, and we shall really get to grips with the question of nature or nurture. It is a welcome sign of the times that Dr. F. A. E. Crew, director of the Animal Breeding Research Department of the University of Edinburgh, has been appointed to give the Milroy lectures next year, and the annual report of the establishment over which he presides with such productive success contains a number of items of interest to human pathologists, as well as material more immediately germane to the objects of the institution, which was founded primarily to make a genetic analysis of farm animals with a view to their improvement. The tassels on the necks of some goats, for example, which are the best available remnant of a cervical ear and have each a little dermoid cyst at their base, are a heritable character and, with qualifications, their presence is dominant to their absence. A study of the pterylosis of the "hackleless" fowls with naked necks shows that the condition is not due to individual disease, but to an inherited defect in the development of the feather follicles in certain skin areas. Male mice treated with alcohol generate proportionately many more male offspring than normal animals, an observation which we hope will not be translated into human legislation without further consideration. An achondroplasia-like disease has been identified in sheep, analogous perhaps to the "bull-dog" calves of Dexter-Kerry cattle. Without going into details of the many other investigations summarised in the report, we may congratulate the International Education Board on finding such a suitable recipient for the £30,000 which they have given to promote the work of the institution.

A DISCUSSION ON RICKETS.

THE Section of Pædiatrics of the Massachusetts Medical Society recently devoted a session to various aspects of rickets, and a number of well-known authorities expressed their views.[1] Dr. J. L. Gamble reviewed the results of experimental work performed on the blood. As the most likely explanation of the mode of ossification of normal bone, he accepts the hypothesis of J. Howland and B. Kramer that precipitation of calcium phosphate in bone is due to the concentration of carbonic acid being lower in the osteoid tissue than in the plasma. There is no reason, however, to suppose that this reduction of carbonic acid concentration fails to occur in rickets and the defective ossification is more probably attributable to the demonstrable deficiency of di-calcium phosphate in the plasma. The Ca × P product may be taken as a theoretical measure of the severity of rickets and the effect of treatment, but in ordinary cases no change is found in the calcium value, and for practical purposes it is only necessary to estimate the phosphorus. A reduction of the calcium in the plasma occurs in tetany, but it is incidental and

[1] Boston Med. and Surg. Jour., Sept. 8th.

transitory and should not be regarded as showing that there are two independent types of rickets. The initial factors responsible for the lack of phosphorus in the plasma have never been completely determined in spite of much research, including experimental production of rickets in young animals. E. A. Park and others found that the two dietetic factors necessary for its development were (1) low or unbalanced intake of calcium and phosphorus, and (2) lack of vitamin D.

In a paper entitled a Plea for Sanity in the Use of the Modern Methods for the Prevention and Treatment of Rickets, Prof. J. L. Morse suggested that the application of therapeutic measures to alleged cases of rickets was grossly overdone. He considered that the purely radiological evidences of rickets, which were so often regarded as grounds for the use of cod-liver oil or heliotherapy, were so common as to be in all probability physiological, and that consequently a large proportion of current treatment was superfluous and meddlesome. Moreover, the indiscriminate use of artificial sunlight brought with it the possibility both of harm to the patient and exploitation of the public. Dr. K. D. Blackfan referred to a group of cases, clinically and biochemically identical with rickets, in which treatment with cod-liver oil and sunlight was unsatisfactory. He also pointed out that craniotabes, whether it was in reality a sign of rickets or not, was unaffected by these remedies.

A NEW IMMUNITY REACTION.

IN 1917 Rieckenberg discovered that when the blood of an animal, which had been cured of a trypanosome infection, was brought into contact with the causal organism there was a specific adhesion of blood-platelets to the surface of the trypanosomes. More recent investigations of this phenomenon have shown it to be a specific immunity reaction and have extended and modified its scope. It has been shown, for example, that neither platelets nor plasma are essentials, and that what appears to be the same reaction occurs if other small particles—e.g., bacteria—are brought into contact with the trypanosomes in the presence of immune serum. L. J. Davis and H. C. Brown, of the Wellcome Bureau of Scientific Research, investigated this phenomenon early in the current year and showed its practicability as an immunity test and its applicability to spirochætes as well as to trypanosomes. In the current number of the *Journal of Experimental Pathology*, the same authors detail experiments which they have carried out with this phenomenon in an endeavour to differentiate between various species of spirochætes (leptospira). These include a type present in London tap-water, the organism of Weil's disease, the spirochæte isolated by Noguchi from cases of yellow fever, as well as an organism supposed to be causal in the seven-day fever of Japan. The results they publish show that the reaction is one which in their hands gives sharply differentiated results, and whilst the first and last of the organisms we have mentioned behave as independent species, the organisms obtained from infectious jaundice and yellow fever appear identical. This conclusion is in diametrical opposition to the results of Noguchi, who claims on various grounds that the organisms are definitely distinct species. The point raised is rather an important one, as it calls into question the relationship of Noguchi's spirochæte to yellow fever—a problem which cannot yet be regarded as settled. The reaction which we are alluding to is a new departure in the field of immunological tests, and its value is as yet unascertained. From the work of Davis and Brown it would appear probable that it is related to the agglutination test, although it seems to differ from this in requiring the aid of complement, which however need only be present in very minute traces. The authors propose the name of "adhesion phenomenon" for the reaction, which would certainly seem to be a convenient and descriptive term and less barbarous than "thrombo-cytobarin test," which has been used on the continent and which is not accurately descriptive of the reaction as at present performed.

UPWARD MOVEMENT OF THE EYES.

DESPITE the refinement of modern technique and the perfection of biological and diagnostic tests medicine will never be an exact science, and there are many who lament the passing of the intuitive practitioner of an earlier day. These may take comfort from the presidential address delivered by Prof. Edwin Bramwell last Thursday to the Neurological Section of the Royal Society of Medicine. His review of so apparently simple a matter as the upward movement of the eyes well illustrated his claim that the neurologist must ever cultivate and jealously preserve the wide mental outlook of the biologist. The essential joy for most people in a new discovery is the light that it throws from a fresh angle on well-known facts. We have all played "hunt the thimble" and can remember how absurdly difficult it is to see a conspicuous object if only it be placed above the level of the head. We have all had headache after gazing at high-hung works of art in a picture gallery. We also know that individuals vary enormously in the extent to which they employ facial movements. We have all seen a windscreen wiper ticking mechanically across the glass of a car, though we may not have associated it with blinking. We have all had a chance of observing the slow blinking movements which accompany steady mental activity, just as we may have remarked the rapid flickers of the eyelid that go with emotional tension which has no outlet—helpless anxiety or rage. We have heard that the eyes roll upwards during sleep, we have seen those of a tired companion rotate up under the drooping lid. And we cannot have failed to see the unconscious mimicry of people's mannerisms. In these isolated items of knowledge, however, we are as uncoördinated as the new-born infant which (Prof. Bramwell reminds us) can neither blink nor shed tears, though it can turn its head towards a bright light and turns up its eyes when the tired lids droop—a movement of lower order than those acquired coördinated movements which are determined by stereoscopic vision.

It remained for Prof. Bramwell to ponder these things and to string the odd beads together into a coördinate chain of links. Why, he wonders, does a person look upwards in disapproval? The devotional upturning of the eyes is understandable; do we "turn up our eyes," in the modern phrase, to appeal for aid against temptation, or to avoid seeing the disapproved object, or to help us in keeping back the verbal expression of doubt or disapproval? Why, again, do we look upwards in mental abstraction? Is it just a release phenomenon, or is it in the hope of inspiration from above? Prof. Bramwell is convinced that the movement is voluntary and purposeful although it may become a habit. In abstraction the pupils dilate, and it may be that this, together with upturning of the eyes, serves to block out disturbing visual stimuli. Without doubt the majority of such expressional movements are picked up by mimicry just as speech is, and the mannerism, when dissociated from the conditions that originally gave rise to it becomes a tic, a habitual purposeless movement. Upward movement of the eyes, so common as a mannerism, is, in Prof. Bramwell's experience, very rare as a tic, perhaps because it attracts too much attention to favour unconscious imitation. Sometimes petit mal patients turn the eyes upwards, and he suggests that a collection of information on this point might prove valuable for prognosis and treatment. Under surgical anæsthesia deviation of the eyes is unusual, he says, though downward rotation specially deep anæsthesia.

The involuntary upturning of the eyes in epidemic encephalitis appears to be a new symptom, associated exclusively with Parkinsonism, of which it may be the only certain diagnostic sign. Prof. Bramwell describes

he 11 cases in which he had studied the symptom, and concluded from them that a part was played by atigue, by agitation, and by self-consciousness. Hyoscine has, he said, a remarkable effect in meliorating the movements, and it was tempting to uggest that an irritative process played a part in their roduction. His explanation was that the vertical novements of the eye predominated in the brain stem —a suggestion that raises again the question of 'mid-brain epilepsy." The experimenter has never et succeeded in producing upward or downward novement of the eyes from cortical stimulation, nor as vertical rotation ever been recorded during a fit. The experiments of Risien Russell confirmed the uggestion of Hughlings Jackson that in the cortex he lateral movements of the eyes are so much more owerfully represented than are the vertical move- nents that they overpower all others when this area s stimulated. Loss of upward movement is pathogno- nonic of brain stem lesion, says Prof. Bramwell, and his is a far older and more primitive coördinate novement than the lateral movements of which we ear so much. To rotate the eyeballs up is to hark ack to a time when all that we have learned from tereoscopic vision was yet untaught.

EXERCISES FOR CHILDREN.

THE Board of Education has just published four dditions [1] to its series of manuals on physical raining. Nos. 10 and 11 (price 2*d.* each) are short amphlets concerned with the physical education of oys over 14 years of age. They briefly describe the eaning of physical education, whose object is not only to improve the physical condition of the upils . . . but to aid in the development of their ental powers and in the formation of character." o this end it is desirable to include in any scheme ystematic physical exercises, games and athletic orts, swimming and dancing. There must not nly be suitable instruction and accommodation, but he teacher must be thoroughly trained and must ork in conjunction with the medical officer. The oard insists that there should be a daily period voted to instruction of this kind and suggests minutes as the minimum, preferably in the orning. The pamphlets do not describe any of the ercises, but refer the reader to the "Syllabus of ysical Training for Schools," 1919, and to the new Reference Book of Gymnastic Training for Boys" o. 13 of the series, price 3*s.* 6*d.*). This "Reference ook" of 322 pages is devoted to a description of the vedish system, and gives a full and clear account of ndreds of exercises for boys between the ages of and 18, each being designed for some particular ysiological effect. The theory underlying these ercises is discussed, and the best method of teaching clearly set out, often with diagrams. In the intro- ction Sir George Newman shows that recent ucational developments have demanded a wider erpretation of "physical exercises" and explains at the Swedish system has been adopted as the best ethod for giving systematic training "to secure rtain definite results which can be more or less actly controlled." It may be, however, that pendence on specific series of movements for lividual purposes is not physiologically sound, cept in cases of organic, surgical, or paralytic fects; for the rounded back or the protuberant domen is an expression of general unfitness, as o are most of the other minor postural and muscular aknesses commonly met with in children. They best countered by a healthy environment and by natural movements of games or dancing which icken and hold the interest. Systematic exercises, sides requiring much apparatus, may be too pendent on the personality of the teacher for staining attention, whereas simple games can be rted in quite early years and the spontaneous y-instinct of the child can be moulded gradually into the communal habits of self-discipline and coöperation with his fellows. The supplement for older girls (No. 12 of the series, price 4*d.*) consists of two parts, the first being a progressive list of gymnastic exercises and the second describing the organisation and practise of many excellent games. Diagrams are given to show how playgrounds can be marked out so as to permit of several games being played at the same time.

[1] Board of Education, Physical Training Series, Nos. 10–13, H.M. Stationery Office.

THE subject of Sir William Willcox's presidential address to the Medico-Legal Society on Thursday next will be Recent Advances in Toxicology and Forensic Medicine. The address will be given at 11, Chandos-street, Cavendish-square, at 8.30 P.M.

Prof. C. Y. Pearson has resigned his post as professor of surgery at University College, Cork, as from the end of October, but is not retiring from active practice, in the pursuit of which he will have the best wishes of many friends. For a long period he has been one of the best-known members of the surgical profession in the south of Ireland, and some years ago was appointed honorary surgeon to the King in Ireland.

Mr. Lionel Colledge will deliver the Semon lecture for 1927 in the Barnes Hall of the Royal Society of Medicine, 1, Wimpole-street, on Thursday, Nov. 3rd, at 5 P.M. His subject will be the Present Position of Laryngectomy for Cancer of the Larynx, and Mr. Harold Barwell, President of the Laryngological Section of the Royal Society of Medicine, will take the chair.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. M. W. Haydon is placed on the Retd. List with the rank of Surg. Capt.

W. J. Moody, W. C. Munro, R. D. Stuart, and J. C. Gent to be Surg. Lts.

Proby. Surg. Lt. W. F. Lascelles to be Surg. Lt.

Surg. Cmdrs.: H. E. Y. White to H.M. Yacht *Victoria* and *Albert*; G. S. Harvey to *Pembroke*, for R.N. Barracks, Chatham, for course, and to *President* for course, and to *Vivid*, for R.N. Barracks, Devonport, for anti-gas school; E. C. Holtom to *President*, for Porton Experimental Station; D. H. C. Given to *President*, for three months' post-graduate course; and K. D. Bell to *Victory*, for Royal Marine Infirmary, Portsmouth. Surg. Lts. E. H. Rampling and C. R. Boland transferred to permanent list.

ROYAL ARMY MEDICAL CORPS.

Capts. to be Majs.: J. H. C. Walker, M. B. King (Prov.), and R. H. Graham.

Capts. to be Majs. (Prov.): Bt. Maj. W. Hunt (and remains secd.) and H. S. Moore.

Temp. Lt. P. J. Malone, Dental Surg., to be temp. Capt.

Temp. Capt. H. M. Hart-Smith relinquishes his commn. and is granted the rank of Capt.

ARMY DENTAL CORPS.

Lt. F. H. R. Davey to be Capt.

TERRITORIAL ARMY.

Capt. A. F. Wright resigns his commn. on reduction of estabt. and retains his rank.

Capt. H. M. Anderson resigns his commn. and retains his rank.

C. L. Broomhead to be Lt.

J. G. Weston (late Offr. Cadet, Univ. of London Contgt., Sen. Div., O.T.C.) to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. F. T. Rees, Active List, to be Lt.-Col.

ROYAL AIR FORCE.

Flight Lt. T. W. Wilson is granted a permanent commission in his rank.

A. W. Comber is granted a temporary commission as Flight Lt.

INDIAN MEDICAL SERVICE.

Maj. R. W. G. Hingston retires.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXLVI.

THE TREATMENT OF LOBAR PNEUMONIA, BRONCHO-PNEUMONIA, AND BRONCHITIS IN CHILDREN.

II. THE TREATMENT OF SPECIAL SYMPTOMS.[1]

Sleeplessness.

SLEEPLESSNESS should be prevented from the start. Nothing so exhausts a child as a succession of sleepless nights, and in a severe case the promotion of sound sleep from the outset may turn the scales. When drugs are given the dosage must be effectual; the hypnotic which fails may do more harm than good. In the early stages, and in many cases throughout the attack, potassium bromide and chloral hydrate, or syrup of chloral, are the best. Children take both well. Tepid sponging often helps to send a child to sleep in conjunction with these. If these milder remedies fail the problem of the use of opium and morphia arises. In an adult this question becomes more delicate as the crisis is approached; in the child an even nicer judgment is required on account of the intense and varying susceptibility of children to opium and its derivatives. There is, however, no doubt as to its value, and in some cases life may depend on correct and timely dosage.

To a child of 3, 1 minim of tincture of opium or 1 gr. of Dover's powder may be given. The dosage in each case must be judged with especial reference to the amount of respiratory distress. It is well to err on the side of under dosage at first and repeat if sleep is not obtained. Morphia is best given hypodermically combined with atropine, which tends to diminish respiratory distress; with the same caution morphine hydrochloride gr. 1/20 may be given to a child of 3. Heroin is said to have a less depressant effect on the respiratory centre, but I prefer to give morphine itself rather than be lulled into a false sense of security by giving heroin.

Pain.—Pyrexia.

Pain in the chest may cause restlessness and lack of sleep and can be relieved by local applications. Since the soft bony framework of a child's chest is easily compressed, any heavy application likely to impede respiration should be avoided. Antiphlogistine or thermogene wool applied to the affected side, or methyl salicylate ointment, are the best local applications. In older children pain from a localised patch of pleurisy may be relieved by immobilising the affected side with strips of adhesive plaster. A mustard leaf will sometimes give relief.

Pyrexia.—Antipyretic drugs should not be given. For a prolonged temperature of over 104° F. tepid sponging is effective and comforting. Start with water at a temperature of about 90° F. and cool while sponging by the addition of cold water. The temperature of the child should be watched and sponging should not be continued after this has fallen to 101° F. by the rectum.

Cardiac Failure.

Much may be done to lessen the strain upon the heart by preventing respiratory distress. When any tendency to cyanosis shows itself, or the secretion in the tubes appears to be interfering with easy respiration, atropine should be given. By drying up excess of secretion and causing the bronchial tubes to dilate, this allows air to pass freely into the alveoli and oxygenation is facilitated. Children stand atropine well; gr. 1/100 may be given hypodermically three times a day to a child of 3, and in severe cases four-hourly. The value of stimulants is problematical. In weakly children, or those in whom there is any abnormal rapidity or feebleness of the pulse, it is well to give a stimulant from the start.

The following is a useful mixture, given three times a day for a child of 3: spiritus ætheris ℥v., spiritus ammon. arom. ℥v., aqua ad ℥i.

There is considerable difference of opinion as to the value of brandy in treatment. Some authorities maintain that it is unnecessary and may even be harmful. Personally, I find it a most valuable stimulant in severe cases and have never observed any ill-effects from its use. Thirty minims may be given four-hourly to a child of 3 directly any tendency to cardiac weakness appears; the dose may be increased to one teaspoonful or more if necessary. Brandy should never be given until there is definite need of a stimulant. Adrenalin appears to be of value in some cases; ℥v. (1 : 1000) may be combined with injections of atropine. Strychnine should be given cautiously to children who are very sensitive to it. In cases of sudden cardiac failure a small and isolated dose is of value; it should only be repeated at long intervals. The value of camphor as a cardiac stimulant is indefinite. For a single dose gr. ½ dissolved in olive oil may be given intramuscularly to a child of 3, or gr. ¼ if the dose is to be repeated at six-hourly intervals. Digitalis is often given to children, but I have never observed any benefit from its use. For collapse in children under 2 years old a mustard bath is the most valuable stimulant. One heaped tablespoonful of mustard is added for each gallon of water in the bath, which should be as hot as can be safely borne, the body being completely immersed for from two to five minutes. The child should then be dried quickly in a warm towel and put straight into bed.

Expectorants.

In mild lobar pneumonia these are not indicated during the first few days. When there is bronchitis or the cough becomes dry and irritating, small doses of ipecacuanha, squill, and ammonium carbonate are useful. A linctus containing a teaspoonful of equal parts of glycerine and syrup of virginian prune, or of equal parts of compound tincture of camphor, oxymel of squill, and syrup of balsam of tolu is good. The bronchitis kettle will often relieve a dry and irritating cough, especially if there is some laryngitis. When there is obvious respiratory irritation from excess of secretion in the bronchial tubes, which an ineffective cough fails to relieve, a single emetic dose of ipecacuanha is of great use.

Fresh Air Treatment.—Oxygen.

Treatment in the fresh air is unnecessary for the simple case of lobar pneumonia. In certain cases of severe lobar pneumonia and broncho-pneumonia with cyanosis and much respiratory distress, removal to the open air causes immediate and marked improvement. If a spot well sheltered from the wind and rain is obtainable in a garden or on a balcony and the child is in the hands of an efficient nurse, the treatment is very valuable. In the absence of these facilities it is better avoided.

Oxygen Administration.—For patients with cyanosis oxygen is useful. It should be given for periods of 15 minutes once every hour, through a catheter introduced into the nose. Administration by means of a funnel held a few inches from the nose and mouth is a bad method and probably of no benefit whatever.

Specific Treatment.

The serum treatment of lobar pneumonia has so far only been doubtfully successful, and that only in cases due to Type I. pneumococcus. To get the maximum effect it must be given as early as possible in large amount, and by the intravenous route. In many children it is impossible to obtain sputum to determine the type of infecting pneumococcus and serological tests are necessary. The giving of serum

[1] The first section of this article—General Considerations—appeared last week.

by the intravenous route to children is very difficult, especially in private practice, and as the infection is much less dangerous than in adults, the scope for specific treatment is less. It may possibly be of use in older children when means for rapid serological diagnosis are at hand.

Complications.

Empyema.—In pneumonia, from the start a close watch must be kept for the development of an empyema. In children the physical signs of this complication are often misleading. In the early stages the most definite sign, displacement of the heart, is absent, while the others are often indefinite. Breath sounds are often not diminished over a thin layer of pus, and high-pitched tubular breathing is often present. Owing to the ease with which sounds are conducted in a child's lungs the sounds may be similar but slightly less on the unaffected side, and it is easy to suspect the empyema on the wrong side. For these reasons the physical signs are less helpful than in an adult, and in cases of doubt it is wiser to make certain by exploration. Should the temperature continue after pus has been found and evacuated, the possibility of a double empyema must not be forgotten. Before resorting to exploration great care must be taken to exclude other causes of continued pyrexia. Examination of the ears, throat, or urine is sometimes forgotten. The treatment of empyema has already been dealt with in this series.

Abdominal distension should be treated in its early stages, for once paralytic ileus has developed very little can be done. A less fluid diet should be given and an abdominal binder worn. Turpentine enemas, rectal wash-outs, or the passage of a high rectal tube may assist in the evacuation of flatus. If distension increases pituitary extract may be given; 0·20 international units intramuscularly is a safe dose for a child of 3. For persistent vomiting the stomach should be washed out.

Convalescence and After-treatment.

Fresh air and avoidance of chill, nourishing food, a tonic, and a graduated return to normal life are the chief convalescent requirements. A holiday in the country or by the sea may be needed.

An attack of pneumonia in a child is an important fact in its medical history and should never be forgotten, especially during a future attack of measles, whooping-cough, or influenza. The possibility of a residual fibrosis of the lung must be remembered, particularly in a child who has had the good fortune to recover from an attack of broncho-pneumonia.

late Resident Assistant Physician to
St. Thomas's Hospital.

Special Articles.

THE NORMAN KERR MEMORIAL LECTURE ON THE TOBACCO HABIT.

Delivered on Oct. 11th before the Society for the Study of Inebriety

BY PROF. W. E. DIXON, M.D., F.R.S.,
ASSESSOR TO THE REGIUS PROFESSOR OF PHYSIC, CAMBRIDGE.

[Prof. Dixon commenced by saying that Dr. Norman Kerr, in whose honour the Memorial Lecture was delivered, had himself written on the evils following the tobacco habit. After a brief sketch of the history of tobacco, the circumstances in which it was introduced into Europe, and the various attempts at prevention by authorities, royal, clerical and military, the lecturer pointed out that smoking had become universal throughout the world, adding that in this country no serious attempt had been made to determine its effect on the public health. He continued:]

Composition of Tobacco Smoke.

The smoke emitted from any smouldering vegetable matter, including tobacco, contains ammonia gas and pyridine or pyridine derivatives, and it is these substances which produce the irritation of mucous surfaces not infrequently observed in those who smoke; these bodies are responsible for the morning cough, the irritation of throat and tongue, and the conjunctivitis of the cigarette smoker. They are in every respect objectionable products and add nothing to the pleasure of smoking. If they could be excluded from the smoke it would be all to the benefit of the smoker. Other dried herbs such, for example, as coltsfoot leaves, at one time sold as a harmless boy's tobacco, often produce more pyridine when allowed to smoulder than tobacco, but they have none of its calming effects.

The pyridine bases are oily volatile liquids, intensely irritant, but compared with nicotine of a relatively low toxicity.[1] Their poisonous nature I have demonstrated on young volunteers who were required to smoke coltsfoot leaves; after smoking for some time, 20–30 minutes, they suffered from nausea, vomiting, and diarrhœa, with all the signs of early shock.[2] Nevertheless in tobacco smoking the only serious effect of these bodies is the local irritation, since their specific effects are insignificant in comparison with those of other substances which are present in this smoke.

Carbon Monoxide.

Another substance obtained from the slow combustion of almost any vegetable matter, including tobacco, is carbon monoxide, which is also the poison of coal-gas and the exhaust gas from motor-cars.

In New York and Newhaven, where the motor traffic is dense, CO can be detected in the air of the streets.[3] The traffic control men not infrequently suffer from headache, slight nausea, muscular weakness and rapid pulse, which are the usual symptoms of CO poisoning. Wilson and others [4] examined the blood of 14 foot traffic patrol men and found that their blood contained from 0–30 per cent. of CO, whilst six of these men showed values of from 20–30 per cent. Two other symptoms which are also prevalent are dizziness, and, more rarely, dimness of vision.

The U.S. Bureau of Mines made experiments to determine the CO present in a confined space after intensive smoking, and found that the CO concentration of the air of the room did not rise to more than 0·01 per cent., and the maximum blood saturation of the subjects exposed to this atmosphere was only 5 per cent. Nevertheless this is more than enough to affect seriously sensitive people. When the amount of this gas is determined in the smoke of cigars, cigarettes, and pipes under conditions simulating as far as possible those obtaining during ordinary smoking, the figures obtained are somewhat alarming.[5] The cigarette smoke yields from ½ to 1 per cent.; the pipe 1 per cent. or more, and the cigar 6 to 8 per cent.; this last, as Prof. Armstrong points out, is roughly the proportion of CO in the coal-gas of the South Metropolitan Company. The amount of CO varies naturally with the rapidity of the smoking and the closeness of the packing—the quicker the smoking the more CO.

Tobacco smoke, however, reaches the mouth freely diluted with air, and the amount of CO absorbed from the buccal cavity is negligible, so that pipe and cigar smokers who do not inhale have little to fear from this poison. Cigarette smokers who inhale would absorb a large proportion of the CO which reaches the lungs, since the affinity of CO for blood is more than 200 times that of oxygen. Cigarette smoke as it reaches the mouth of the smoker may contain as much as 7·2 to 25 parts of CO in 10,000 parts of air (Baumberger). Inhaled for one hour at the rate of five puffs a minute this should be enough to affect

appreciably the blood hæmoglobin. Many years ago Fokker asserted that animals placed in an atmosphere containing tobacco smoke died from CO poisoning. Hartridge [6] found 6 per cent. CO in the blood in one cigarette smoker who was by no means excessive in his habits. The normal healthy man does not in most cases show symptoms of CO poisoning until 15 to 20 per cent. of his hæmoglobin has been fixed and put out of action. Yet there are many people who show a supersensitiveness to this poison, just as some of us have some idiosyncrasy for quinine or iodides, and so it is not difficult to appreciate why cigarette smokers may exhibit a syndrome indistinguishable from that of mild CO poisoning.

The toxic concentration of CO in the atmosphere is about 0·05 per cent.; in men exposed to dilute concentrations such as 0·02 per cent., the degree of hæmoglobin saturation would be perhaps somewhere near 20 per cent.[6a]

Nicotine.

The third and by far the most important constituent of tobacco is the volatile alkaloid nicotine. The effects of cigar and pipe smoking are due practically entirely to nicotine which exists in tobacco combined with organic acids. During smoking these salts are largely dissociated, a part of the nicotine being burnt, and a part passing in the smoke as free nicotine. The drier the tobacco the greater the destruction of the nicotine. Moist tobacco produces much more serious effects than dry tobacco, and it has been stated that the moistness of the tobacco is responsible for many of the evils. The water content of the tobacco is much more harmful to the smoker than the original nicotine content of the tobacco.

During the slow combustion of a cigar, as in ordinary smoking, there is an area immediately behind the point of combustion in which the water and other volatile substances condense. During aspiration the hot gases are drawn through this hot moist area and carry with them the volatile principles of which nicotine is the most important. Hence the smaller this moist area behind the point of combustion, which means the cooler the smoke or the more complete the combustion, the less likely is the smoke to contain volatile toxic bodies. It follows that a cigarette or slender cigar which is well cooled will yield fewer of these products than a thick cigar, and many smokers can testify that a fat cigar has a much greater effect than a long slender cigar of similar tobacco. This also explains the unpleasant effects of relighting a half-finished cigar or pipe.

The same principle is exemplified by the following fact. Virginian tobacco leaf from which cigarettes are made often contains double the amount of nicotine that is present in Manilla cigars. Yet when an equal weight of the cigarettes and cigars are smoked the total cigar smoke contains double the amount of nicotine present in the cigarette smoke. The condition of the tobacco and the form in which it is smoked are more important factors in determining the amount of nicotine in the smoke than the amount of nicotine present in the original tobacco.

The species of plant mostly used is *N. tabacum*, but several other species are employed, thus *N. rustica* yields Turkish tobacco; different varieties of tobacco from the same species also show different amounts of nicotine. During the process of curing the leaves, which consists in exposing them under cover to a considerable degree of heat, important chemical changes occur, the leaves become moist and their fragrance alters. There is much room here for further investigations with a view to producing a tobacco which when smoked would yield in the smoke the minimum of alkaloids, pyridine, &c., whilst retaining its aroma. Tobacco may contain anything from 1 to 8 per cent. of nicotine; Havana tobacco has about 1·5 per cent.; Maryland, 2 per cent.; Virginia, 6 per cent.; Kentucky, 8 per cent.

Amount of Nicotine in Smoke.

The amount of nicotine in tobacco is no criterion of the amount in its smoke. For example, mild Honeydew contains only 1·6 per cent., whilst Cavendish may contain as much as 3·8 per cent.; if these two are smoked under identical conditions the Cavendish naturally yields the larger amount of nicotine in the smoke. But Cavendish smoked in a cool pipe, or one provided with a filter, will affect the smoker less than the Honeydew smoked in a hot pipe. In the churchwarden pipe the opportunity for the nicotine to condense is such that the smoke is almost freed from the alkaloid; and I have already pointed out that in cigar and cigarette smoking the degree of moisture, the tightness of packing, and the thickness of the cigar or cigarette are the most important factors in determining the amount of nicotine which will be present in the smoke.

Habermann [7] and Ehrenfeld state that two-thirds of the nicotine of some kinds of cigars passes over in the smoke; with other brands as little as one twenty-fourth passes over. Lehmann [8] obtained nicotine from the air of a room in which tobacco was being consumed, showing that the smoke puffed out is by no means denuded of all its alkaloid. He thinks from his calculations that only about 1·4 mg. nicotine are absorbed from a cigar. This figure depends on so many conditions that it cannot be accepted; for example, the length of time that the smoke is held in the mouth, thus affording time for absorption, would exert an enormous influence. Our own observations suggest that the figure is ten times too small. The collapse which I have seen in youths smoking Manilla cigar could not have been obtained by the absorption of such an amount.

Asherton, 1919, says that 6 to 8 mg. of nicotine reach the mouth from a cigarette smoked in the usual way. We are not told, however, how much of this is likely to be absorbed. In our own observations using a standard Virginian cigarette weighing 1 g. and aspirating the smoke through solvents once in 12 seconds and using only three-fourths of the cigarette, it was found that 3 mg. of nicotine were absorbed. It must not be assumed that all this is necessarily absorbed into the system, but in the case of an inhaler most of it certainly is, perhaps 75 per cent., since expectoration is no longer permitted and loss can occur through the exhaled smoke only. Hence if a cigarette smoker were to puff ten cigarettes on end he would certainly absorb 20 to 30 mg. of nicotine, enough to produce a profound physiological effect, though administered in this way perhaps 10 to 15 times under the lethal dose. The amount of nicotine in pipe and cigar smoking is much higher. In our experiments cigar smoke contains about twice as much nicotine as cigarette smoke.

Other constituents of tobacco smoke are less important. The solids of cigarette smoke weigh about 10 per cent. of the tobacco burned—that is 80 mg. for each cigarette. Cyanides and sulphocyanides are present in traces, arsenic is a constituent of American tobaccos in amounts many times greater than those permitted in foods. Pipe tobacco is reported to contain the equivalent of from 0·05 to 0·27 gr. As_2O_3 per pound.[9] When smoked probably about half this will be absorbed.

These facts show that nicotine is a most important constituent of tobacco. It is one of the most fatal and rapid poisons known; it acts as quickly as prussic acid, and 2 drops placed on the tongue of a dog will kill it almost immediately. The lethal dose for a man is 60–120 mg. The nicotine present in one cigar if injected intravenously would represent two fatal doses to man. It is therefore somewhat remarkable that fatal nicotine poisoning is not more common. Nevertheless, the careless use of tobacco infusions as enemas, the occasional swallowing of tobacco leaves or even carrying tobacco leaves next to the skin for smuggling purposes, have all led to fatal results. Tobacco has also been used for criminal purposes, but as it does not appear to undergo fermentative changes in the cadaver it can be detected in the bodies of animals three months after death.

[Prof. Dixon then reviewed the subject of denicotinised tobacco, the various methods of removing

icotine suggesting to him that great opportunities ill existed for the investigation of tobacco.]

General and Specific Action of Tobacco Smoke.

Tobacco used in any form possesses irritant pro-erties; this is, of course, obvious with snuff, the use which depends on stimulation of the fifth nerve-ndings. The same action occurs in chewing which xcites reflex salivation. If 5 or 6 gr. of tobacco are vallowed vomiting occurs. Tobacco is irritating lso to the skin, and the alkaloid in it is readily bsorbed. Many cases of poisoning are on record, nd I have in mind particularly a child of 8 years ffering from tinea capitis to whose head the expressed ice of tobacco leaves was applied; the treatment as shortly followed by the death of the child. everal cases of tobacco poisoning from the skin are ported in the *British Medical Journal* for 1926. arvin, in 1913, described the case of a girl aged years who died 45 minutes after receiving an enema 24 gr. of tobacco. From an examination of such ses it is clear that death may occur from three inutes to several hours, after using tobacco as an ema or for application to the skin.

Continuous smoking for several years not infre-ently produces signs of chronic irritation in the outh, throat, and larynx—sore tongue, morning ugh, hoarseness, tonsillitis, or chronic bronchitis. believe that these effects are most marked in the garette inhaler. When the smoke is concentrated one portion of the tongue for many years, which ay occur especially in pipe smoking, this constant itation is said to favour the formation of epithelioma the lip and tongue if the quantity consumed is ge or the smoker predisposed. The evidence in pport of nicotine taking any part in this action is rtainly not conclusive. Nevertheless, Bottini men-ons 100 cases of cancer which he saw, including three omen, which were caused by smoking or chewing bacco. On the other hand, the Registrar-General's port shows a remarkable fact, to which attention s not been drawn previously, that tobacco manu-cturers have a lower death-rate from cancer than ose of any other trade.

Smoking is reputed amongst the public to have an tiseptic action, and is sometimes indulged in minally for this purpose. Pepys describes the use tobacco during the plague, and its use was com-lsory at Eton in 1721 as a prophylactic against he apprehension." Puntoni[12] and others have own that tobacco smoke has a strong disinfectant ion in vitro. When the smoke is drawn into the uth, however, the action is attenuated by the iva and mucosa, and its antiseptic effect is negli-le. The action in vitro is not influenced by filtering e smoke free from nicotine by passing it through ton-wool.

Smoking is, however, indulged in by man because its sedative action, and this is due solely to nicotine sorption. Nicotine stimulates all nerve-cells roughout the body without exerting any kind of ective action, and the stimulation is followed by pression. The time the stimulation lasts depends various factors, but as a rule it coincides with the sorption of the nicotine—that is, with the period active smoking. Both the pleasure and evils of oking are intimately connected with nicotine. rphine, heroin, cocaine, and the other drugs of diction have a selective action on the central rvous system alone; nicotine is different, it acts o on the autonomic nervous system, and it is this ion which produces objectionable effects in the sitive or excessive smoker.

Alimentary Canal.

The commonest symptoms of smoking are loss of petite and chronic intestinal catarrh. The smoker's k of appetite, Sir Humphry Rolleston thinks, is t altogether an evil, since it limits the consumption unnecessary food. Nicotine and tobacco smoking, stimulating the autonomic ganglia, increase the retion of the alimentary glands and later, after the smoking has ceased, depress them; hence the salivation during smoking and the dry mouth the following day. The same fact is true of gastric secretion. Experiments have been made on dogs with a Haidenhain's fistula, by means of which the secretion of gastric juice may be collected and examined as desired. Injections of nicotine, or saline solution through which smoke has been passed, into these animals afford a means of determining accurately the effect on gastric secretion. Both affect the dog in the same way and cause at first a decided increase in gastric secretion.[13] It is well recognised that in certain persons excessive smoking leads to this gastric hypersecretion; hyperacidity is the most common disturbance and gastritis acida is one of the most frequent results. Hurst[14] believes that tobacco smoking is one of the most frequent causes of hyperchlorhydria. Rolleston[15] lays considerable stress on the relative sensitiveness of the individual as an important factor in determining whether or not a heavy smoker will pay the penalty of gastric disease.

On the musculature of the alimentary canal the action of tobacco is equally well marked, the automatic movements are first inhibited and later augmented as a result of stimulation and later depression of the autonomic nervous system.[16] The inhibitory stage is almost coincident with the period of smoking, and is associated with contraction of the pyloric and ileocolic valves. Stimulation of the sympathetic nerves causes inhibition of the whole alimentary canal with the exception of these two valves which are contracted. The dyspepsia often following on a hypodermic injection of morphine is probably due to this pyloric contraction which delays the passage of food. Morphine in this respect shows some similarity to nicotine.

The mild laxative action of tobacco smoke may be explained by the ultimate depression of the inhibitory cells whereby the motor nerves assume an undue influence on the automatic movements. Hunger is due to certain well-recognised automatic contractions of the stomach; smoking definitely inhibits these. Hence continuous smoking staves off the pangs of hunger and acts in this respect like the drugs of addiction, cocaine and morphine. Careful experiments which have been made on habitual smokers and non-smokers with the aid of bismuth and X rays show that the effect of smoking a cigar is to stop the normal automatic movements of the stomach within 15 minutes. The inhibition continues until about three minutes after smoking has ceased, when the contractions recommence.[20] In these experiments it was also shown that nausea and vomiting from excessive absorption of nicotine may occur at a time when the stomach movements are completely inhibited.

Tobacco smoking, then, has a very definite action on the alimentary canal. In certain sensitive people it produces effects which, according to Hurst, favour the production of duodenal ulcer, whilst Wagner[21] insists that excessive smoking can produce all the subjective and X ray appearances of this condition.

Effects on the Circulation.

The considerable use of tobacco in any form invariably produces certain definite effects on the circulation which cause no inconvenience of any kind to the subject; these should be distinguished from other effects which only occasionally occur, but are then often sufficiently distressing to induce the sufferer to seek medical advice.

Under the first group must be included changes in the pulse-rate. All observers are agreed that the use of tobacco increases the pulse-rate from 5–10 beats a minute, and in the case of the man who is continually smoking the increase of rate becomes permanent, but this condition produces no apparent disadvantage. When the novice or moderate smoker puffs a cigar the rate of the pulse increases in a few minutes. Lee,[19] working in my laboratory, demonstrated this clearly both in the novice and moderate smoker under strict experimental conditions. In another series of experiments 28 young healthy smokers were required

to smoke a single Turkish cigarette; the pulse-rate increased in all but four, and 16 showed an increase of more than eight beats per minute.[20] Hesse[21] obtained similar results with cigars on 25 patients suffering from various chronic diseases.

During the war it was generally asserted that excessive smoking, particularly of cigarettes, was the common cause of the so-called D.A.H. Observations were made which showed that the average pulse-rate of the patients during smoking was nine beats per minute higher than before smoking; in ten healthy controls it was six higher.[22] As there can be no question that the effect is due to nicotine, inhalers of cigarette smoke should show more acceleration than non-inhalers. In Parkinson's 20 patients the 10 inhalers showed an average increase of pulse-rate of 11 per minute and the 10 non-inhalers of 7.

This increase in the pulse-rate is associated with a small rise in blood pressure; for the moderate smoker the rise does not usually exceed 20 mm. of Hg systolic and 8 mm. of Hg diastolic, and is usually even less. The rise begins a few minutes after the smoking has commenced, and is maintained throughout the smoking period.[21 23] It is only in the case of the novice or after excessive smoking that the blood pressure falls to any extent below normal after the smoking has ceased; but under certain conditions the fall may be so severe as to cause all the signs and symptoms of shock or collapse.[22]

Observations have also been made to determine the effect of smoking continued over a period of six months. Nicolai and Staehelin smoked six or eight cigars a day for six months. They then gave up smoking except for an occasional cigar for a further six months. Their average pulse-rate was 74·5 compared with 81·8 during the smoking period.[24]

These changes from the normal are after all usually small and give rise to no symptoms, but the evidence available suggests that they cannot be regarded with indifference. It is a maxim with those who are in training for athletic events that smoking must be entirely eschewed. This prohibition, no doubt adopted in the first place as the result of experience, has become a tradition. In Nicolai's experiments the acceleration of the pulse which occurred after the performance of a measured amount of work with the ergograph was considerably greater during the smoking period, while recovery to the normal rate was much slower than during the period of abstinence. Parkinson and Koefod also showed that smoking a few cigarettes can render healthy men more breathless on exertion, and that this effect was marked in soldiers suffering from D.A.H. This means that the heart even of the moderate smoker is less efficient in periods of strain. It is possible, then, that the prohibition of smoking for athletes is dependent on this vascular effect. With present knowledge it would be mere speculation to attempt to gauge the significance of this factor when continued over many years.

Of the more definite effects which cause patients to seek advice are palpitation and arrhythmia which are relatively common in the young; they disappear if the smoking is stopped, though in pronounced cases, as the late Sir Clifford Allbutt pointed out, only after the abstinence has been continued for many months. The arrhythmia is functional and is usually due to extra-auricular systoles. Neuhof mentions fibrillation and flutter and sino-auricular block also; the block in the case he illustrated disappeared three days after the smoking ceased,[25] but such cases must be very rare. Rolleston says that arrhythmia may occur at any age, but is more noticeable after 50; this may be due to a loss of tolerance which is known to occur in later life, and to which I must refer again. Another symptom which may arise from excessive smoking in later life is anginoid pain, which, according to Osler, rarely approximates to true angina. Turney says that it is associated with vaso-motor disturbances and tends to occur after meals or in the night rather than after exertion.

Arterio-sclerosis is easily produced in animals, especially rabbits, by the injection of nicotine, and we have ourselves produced marked arterial change in the aorta and larger arteries of animals by administering to them "smoke water"; but I do not think that these experiments are proofs that smoking lead to arterio-sclerosis in man, although there is a consensus of clinical opinion that immoderate smoking favours arterio-sclerosis. Pawinski[29] states that 42 per cent. of 1000 cases of coronary sclerosis had histories of immoderate smoking.

In severe cases the cardiac irregularities may lead to syncope, and an undue proportion of sudden deaths occurring during the middle period of life without any definite lesion being found post mortem is said to be found in heavy smokers.[13] As even the most moderate smoking places some disability on the heart, trifling though it be, it may well be that this view deserves serious consideration.

Central Nervous System.

Nicotine is essentially a nerve poison, but so far consideration has only been given to its action on those cells on the course of the autonomic system, and the action is responsible for the digestive and circulatory effects. But nicotine affects the brain and cord also; it increases spinal reflexes and removes certain inhibitions.

I have already drawn attention to some of the effects of excessive cigarette smoking in the young, the attacks of giddiness and the tremors. A large experience of examination papers of medical students enables me to pick out with certainty the heavy cigarette smokers from the irregular character of their writing. If the habit is broken the writing at once improves and the vertigo disappears. These effects are exactly those of CO poisoning and I believe can be explained on this basis.

Habitual smokers are agreed that the weed acts as a mild sedative to the central nervous system; this type of action is of a somewhat remarkable character and may offer an explanation of the widespread use of tobacco. Physical fitness or well-being is determined by our feelings, which are the result of sensations. If response to sensation varies from the normal, whether on the hypo- or hyper-side, remedy causes a return towards the normal, and smoking is said to exert a similar effect though of a more marked description, and hence the sedative effect of tobacco in conditions of irritation, and the stimulating effect in those of weariness and depression. The experiments from which these statements were deduced consisted in determining the threshold to single breaks induction shocks of two fingers immersed in saline solution. After this figure was determined the subject smoked two cigarettes and his threshold was re-examined. If the initial threshold was low, smoking depressed it on an average 72 per cent. On the other hand, if the initial threshold was high, smoking lowered it on an average 28 per cent. Suitable controls were made with cubebs cigarettes which always acted as a stimulant. This shows also that the tobacco action is due to nicotine.[27] In the same way smoking tends to nullify the slight sensory depression produced by the veronals, antipyrine and other hypnotics.[28] So that it may well be that tobacco is helpful when the sensory threshold is abnormal.

Mental Efficiency.

Mental efficiency tests on the whole have not been very convincing. In Berry's experiments[29] smoking enabled his subjects to do more rapid and correct arithmetical addition, but the nicotine here was not the determining factor, the aroma had some effect, and holding an unlighted cigar or chewing substances like gum all had some effect. Turney lays much stress on the importance of these tics. Carver's experiments consisted in applying eight established psychological tests in a number of people to determine whether cigars or cigarettes would influence their judgment and response to stimuli. The results suggest that smoking lowers the accuracy of fine coördinated reactions and association-thought processes. The speed of complicated reactions was, how-

ver, unchanged. The habitual smoker when deprived f his smoke for some hours showed diminished ccuracy.[39]

Many observations have been made by merely omparing the efficiency, mental or physical, of mokers and non-smokers. All these experiments eem to me so difficult to interpret that their value is egligible. Generally they show some inferiority of he smokers. This is true of observations of scholarhip,[31] endurance of telegraph workers,[32] scholarship nd physical efficiency at Antioch,[33] and resistance to uberculosis.[34] The apparent inferiority may be the ause or the effect of the tobacco habit. Those who re handicapped by neurosis or other form of inferiority ould succumb most easily to the euphoria of smoking.

The action of smoking on the performance of outine muscular work has also been examined, and has been found that habitual smoking has no bvious effect on the output of work amongst glass lowers, a moderately strenuous physical occupation, lthough chewing greatly diminished the output.[35] n the other hand, Lombard's experiments show that moking diminishes muscular endurance both at the ge of 35 and 60.[36] Using the ergograph Palman ound that cigarette smoking at first increased uscular work, but that fatigue set in earlier and the otal work was less. A curious periodicity occurs in ie ergograph records after smoking, due to fatigue depression of the central nervous system.[37]

It must be conceded that ordinary smoking in ormal people does not lead to nervous disturbances. xcessive smoking is another matter and may produce nxiousness and insomnia. Every smoker knows that stronger cigar than usual may keep him awake, ough usually the effects of smoking are soothing nd favour sleep. Neurasthenic subjects are easily ffected by smoking, they are continually breaking f their smoking and returning to it again in a few eeks. They suffer from headaches, dizziness, and idden sharp attacks of pain in the head, over the ecordial region or in the stomach, which cease when ie smoking is stopped.[38] Neuralgias generally stated be localised about the intercostals, humoral and apular region are rare but of importance, as until e cause is removed the pain continues.

The action of tobacco, then, on the central nervous stem when used in moderation on the whole does harm, and in subjects showing deviations from the ormal it makes for good.

Amblyopia.

Tobacco amblyopia stands alone in mischiefs so ave. It was noticed by Mackenzie in 1835, and bserved accurately by Hutchinson in 1864. The ght gradually becomes dim with central scotoma, me derangement of accommodation and often latation of the pupil. This condition is associated th retrobulbar optic neuritis, and recovers if oking is stopped; when degeneration has set in, wever, abstaining from nicotine will only arrest ther progress.[38a]

At one time those engaged in the manufacture of bacco, in consequence of the absorption of powder, ffered from visual troubles. Dr. Norman Kerr ated "in 3000 workers in a tobacco factory 150 had e defects, 45 being seriously affected." Galezowski, Schweinitz, and many others have verified these ts. Nevertheless with improved sanitary arrangeents these effects have now disappeared.

Androgué, in a critical analysis of 48 cases of mblyopia from axial neuritis due to nicotine, says e quality of the tobacco is at fault; it was imperctly dried, which means that the percentage of cotine in the smoke is much greater than usual.[39]

[Prof. Dixon concluded by referring to what is own of tolerance to the tobacco habit, and analysed e reasons for smoking, and concluded as follows:]

Conclusion.

Tobacco smoking serves as a mild stimulant followed by a slight degree of narcosis, the supersensitive come calm and lose their irritability, and the dull and apathetic are stimulated. The physiological evidence clearly points to this effect, but the explanation has yet to be learned. But smoking leads to digestive and circulatory disturbances. There is an increasing impression amongst clinicians that the insidious action of nicotine spread over many years of continuous absorption is responsible for at least some of the cardiovascular diseases so common in middle and later life.

It may be argued that if nicotine adds to the agreeableness of life, why not use a path so pleasant? In persons of vivid sensations, to calm the commotion of conflicting sensations may be beneficial, even to the higher faculties; in the dull and listless to stimulate thought must be beneficial. It may well be that living in a civilisation such as ours, under the strained conditions imposed by residence in cities, the ordinary man shows in his nervous responses variations from the normal, and on such tobacco exerts a beneficial function. To what extent strict moderation in the use of tobacco leads to vascular degeneration is uncertain: is it the rule or the exception? This is the vital question to which we require an answer, and upon this answer something of the well-being of the nation depends.

In conclusion, I venture to suggest that the collective sagacity of this Society and that of the medical profession as a whole could occupy itself with no subject more important to the nation than that of tobacco smoking.

A NEW ISOLATION HOSPITAL AT SOUTHPORT.

ON Oct. 14th Sir George Newman, on behalf of the Ministry of Health, opened the new isolation hospital built by the Southport Corporation Health Committee. The new building, which he described as something unique of its kind, replaces two old hospitals: a temporary isolation block in Moss-lane and a small infectious diseases hospital in Shaftesbury-road, now used for tuberculosis. The site of 170 acres was purchased in 1923, but the coal stoppage last year caused delay in completing the building. The hospital stands on the highest part of the land and occupies 12 acres, the rest being let as a farm. There are two scarlet fever blocks with 42 beds, a diphtheria block accommodating 20 patients, and an observation and discharge block. There is also a tuberculosis pavilion (Fig. 1), entirely cut off from the other part of the hospital and divided into two sections, for men and women. Twenty-two patients can be taken here, and outdoor shelters provide eight more beds. It is provided with two recreation-rooms and a common dining-hall, and the whole building is laid out in an up-to-date manner. The floors are covered with wax-polished oak blocks and the wide oak doors are made so that the upper glazed parts can be used as windows and opened in any weather. The usual offices include a special steriliser for sputum mugs.

The fever blocks (Fig. 2), as well as the tuberculosis building, are designed to obtain a maximal amount of sunlight. On the south side of each is a verandah wide enough to take the beds. Each pavilion has two single wards for private patients, and there is a day room in each for convalescents. Other small wards take two or four patients. The observation block has eight single rooms, opening on to a southern verandah. The dividing walls are fitted with large plate-glass panels for observation. Ample and well-segregated sanitary accommodation is provided, and special combination bedpan, bottle, and mackintosh sinks with foot control taps are fitted in each annexe.

The administrative block contains rooms for the visiting doctor, matron, nurses, and servants, and the kitchen is equipped with electric and steam cooking ranges. Power is supplied from the power block, which contains boiler house, laundry, calorifier house, transformer, and disinfector rooms, garage and water-softener room. Behind it is a small mortuary with two post-mortem slabs. The sewage is purified on the premises and discharged into a neighbouring brook.

The entire hospital is surrounded with a belt of pine trees and an unclimbable fence. The buildings are all one-floored, of brick and Welsh slates, and the white enamelled walls of the wards are faced with plaster finished in Parian cement. The sanitary annexes and corridors have a white glazed-brick dado up to 4 ft. 6 in., with plaster finish above. The ward windows are of the metal "Austral" type. The duty rooms and wards are warmed with open fires, low-pressure heating system, and electric heating.

The estimated cost of the buildings is £81,000. The staff is to consist of a matron, 4 sisters, 14 nurses, 12 servants, a gardener, an engineer, and an ambulance driver. The three latter have cottages in the grounds.

The Health Committee hope soon to add an X ray block.

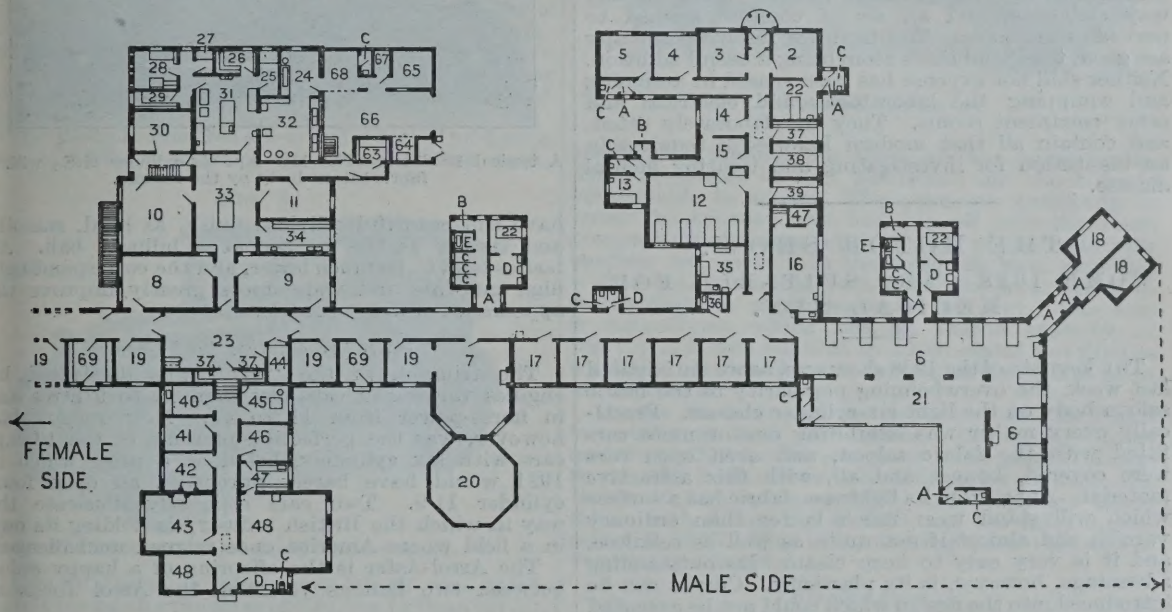
ST. ANDREW'S HOSPITAL FOR MENTAL DISEASES, NORTHAMPTON.

IN 1804 an anonymous donor presented to the governors of the Northampton Infirmary a sum of £100 "towards carrying on their design of making a provision for persons disordered in their mind." This was the beginning of the "Northampton General Lunatic Asylum," opened in 1838 for 52 pauper and 30 private patients. From 1876 only private patients were received, and the institution became known as the St. Andrew's Hospital for Mental Diseases, now the largest of the 13 registered hospitals of England.

The foundation-stone of a new reception hospital was laid on June 27th, 1924, and the completed building, accommodating 32 patients, was opened on Friday, Oct. 14th, by the Lord Chancellor. In a hospital for patients who have a reasonable prospect of recovery the reception department is, perhaps, the most important of all. In mental disorder the coöperation of the patient is even more essential than in physical disease, and first impressions of an institution may make all the difference between confidence and despair or negativism. In planning their new building the governors have aimed at providing every possible equipment for the treatment of early mental disorder, and at segregating noisy patients. At the opening ceremony Lord Cave expressed a hope that voluntary submission to treatment would soon be extended to county hospitals.

The block stands in its own gardens on a site sloping southwards, and has roughly the shape of the letter E, nearly two-thirds of which are shown in the figure. Along the vertical stroke of the "E" lie single rooms, for men and women, on either side respectively of the central horizontal. Near the middle block are day-rooms, cloak-rooms, and solaria. At each extremity of the vertical are dormitories each with 10 beds and large verandahs opening off them on to which beds can be wheeled. Jutting off from each dormitory is a single two-room suite, trebly isolated by sound-proof doors, where noisy patients can be treated. Bathrooms are provided both off the dormitory and off the corridor linking the single rooms. Each of the upper and lower horizontals of "E" contains admission and examination room, waiting and visitor's room, linen and store cupboards, a massage-room, and a large hydrotherapy hall. The latter contains three prolonged-immersion baths and an electrical bath, and the latest appliances for sprays, needle baths, massage douches, and lavage have been fitted, as well as a Turkish bath. A special room is devoted to various kinds of hot packs, and at the junction of each horizontal with the vertical limb of "E" is a large clinical room where the oculist and rhinologist can do their work, and where such investigations as fractional test-meals, blood examination, and the collection of samples can be carried out. In this room special treatments for focal sepsis are to be given.



Plan of ground floor of hospital. The female side is not shown as it is a replica of the male side. An upper story over the central block contains operating room, laboratories, and staff quarters. (1) Entrance; (2) admission and examination-room; (3) nurses' duty room; (4) waiting-room; (5) visitors' room; (6) dormitory; (7) day room; (8) female dining-room; (9) male dining-room; (10) nurses' mess-room; (11) orderlies' mess-room; (12) hydrotherapy; (13) Plombières; (14) massage; (15) dressing-room; (16) clinic and oculist; (17) single rooms; (18) detached single rooms; (19) sitting-rooms; (20) solarium; (21) verandah; (22) bath-room; (23) main hall; (24) vegetable scullery; (25) pantry; (26) kitchen pantry; (27) milk larder; (28) larder; (29) cooks' store; (30) servants' hall; (31) kitchen; (32) scullery; (33) servery; (34) glass and china; (35) ward kitchen; (36) pack-room; (37) store-room; (38) patients' clothes; (39) linen; (40) dispensary; (41) consulting-room; (42) doctor; (43) medical library; (44) bed lift; (45) dental room; (46) photography; (47) dark room; (48) X rays and electrical treatment; (63) boots and knives; (64) washing shed; (65) coal; (66) yard; (67) wood; (68) covered yard; (69) cloak room. (A) cut off lobby; (B) soiled linen; (C) W.C.; (D) lavatory; (E) housemaids' sink.

In the central horizontal of "E" are the dining-rooms, grouped around a servery which communicates with the kitchens, occupying the free end of the block. An extension of this line across the vertical—i.e., southwards, provides an administration block, with consulting-room for psychotherapy, medical library, and dental room. In this is a special X ray unit for photographing teeth, and a photographic and dark-room adjoin, so that every facility for modern dentistry is at hand. The main electrical departments lie just behind, and are equipped with the latest type of apparatus for diagnosis and treatment, including artificial sunlight, diathermy, and high-frequency installation.

The first floor only extends over the middle horizontal and a little way along the vertical on each side. In the latter part the nurses have their rooms, while the domestic staff are housed above the kitchens. The operating theatre, over the dining-rooms, is connected with the ground floor by a bed lift. Above the administrative block are the two laboratories, one for biochemical work, and the other for bacteriology and pathology. They are designed to work in close coöperation with the clinical rooms, where preliminary and simple investigations are to be carried out.

Specific researches also are to be made; the bacteriological side will begin with special cultural methods, and the biochemical side with the chemistry of the blood.

The whole of this hospital unit is for 32 patients, 16 of each sex. The single rooms in which they are accommodated are about 12 feet square, the feature of squareness giving a sense of increased size and being a pleasant change from the usual oblong shape. The doors of these rooms are all made wide enough for the bed to be wheeled out into the corridor, that the patient may be taken to the examination or treatment rooms, or outside, without getting up. The wards (or dormitories) at the ends of the corridors are broad and roomy, their south walls being formed of large glass folding doors, which give onto the wide verandah.

The furnishing and decoration of the building throughout is very pleasing without being in any way elaborate, and an air of comfort seemed to pervade the rooms. The facilities for hydrotherapy are good, the Plombière's room being a useful addition. Neither skill nor expense has been spared in designing and equipping the laboratories and electrical and other treatment rooms. They are elaborately fitted, and contain all that modern knowledge requires in an institution for investigating and treating mental disease.

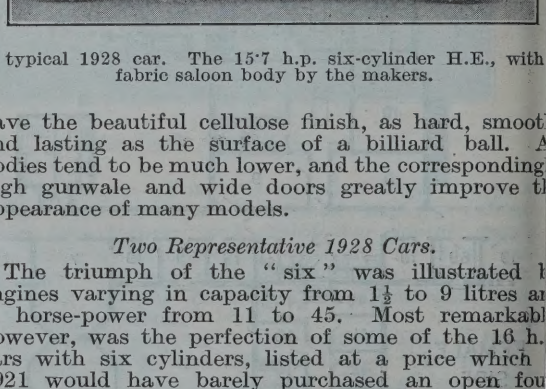
THE MOTOR SHOW.

SOME 1928 CARS SUITABLE FOR MEDICAL MEN.

THE keynote of the 1928 show was, as we anticipated last week, the overwhelming popularity of the fabric saloon body on the light six-cylinder chassis. Practically every maker was exhibiting one or more cars fitted with the fabric saloon, and even open cars were covered, bonnet and all, with this attractive material. Apart from its lightness, fabric has a surface which will stand wear much better than ordinary varnish and almost if not quite as well as cellulose, and it is very easy to keep clean. Its outstanding advantage, however, is its plasticity. Curves can be introduced into the design which could not be executed in a coachbuilt body. The typical fabric saloon at the show is dropped as low as the frame will allow, to give good headroom, with a roof that may not be above the eye-level of a tall man; the running board is also kept low and the wide twin doors, separated by the slenderest of pillars, open a bare six inches above it. A slight vertical as well as horizontal bulge in the sides gives the car the appearance of being adapted to its element like a ship or an aircraft, and the aftermost window on each side, difficult to insert with this type of construction, is replaced by a dummy folding-arm. At the back of the car, beneath the wide rear window, is a spare wheel on a neat bracket, a luggage-grid, and a trunk covered with the same fabric as the body. Some saloons have a roof which folds back like an ordinary hood—a device which for many will remove the last objection to a closed body. Many makers, especially of the lighter cars, fit the Kopalapso roof, made by a firm long famous for easily worked hoods, and the entire roof of the Tickford Sunshine Saloon winds off, on turning a handle, and folds back like an ordinary hood. The Pytchley Automobile Co. make a sliding roof which can be fitted on an existing body. It is generally admitted that the best fabric saloons are made by Gordon England in this country and Weymann in France.

Practically every car this year has a well-planned illuminated dashboard and cubby-hole, shelves or a parcel net, an air strangler for easy starting, and an automatic windscreen-wiper. Saloon windows are nearly all of plate glass with mechanical devices for opening and good blinds, and many cars have an adjustable visor to protect the driver from a setting sun or approaching headlights. Windscreens are now made in one piece, hinged at the top; the joint of the divided pattern hardly ever stood th test of a really stormy day. Other uniform feature are four-wheel brakes, shock absorbers, and sem balloon tyres; most cars have dipping headlight some have swivelling lamps and fog-lamps pointin to the curb, and practically all have some dimmin device. Most speedometers seem to be by Jaege The transparent number plate is coming into it own, and the few saloons not covered with fabr

FIG. 1.



A typical 1928 car. The 15·7 h.p. six-cylinder H.E., with fabric saloon body by the makers.

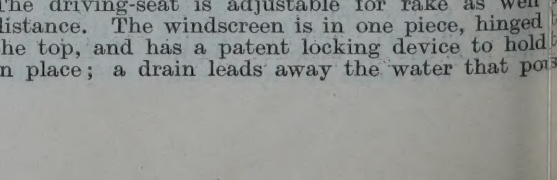
have the beautiful cellulose finish, as hard, smoot and lasting as the surface of a billiard ball. A bodies tend to be much lower, and the corresponding high gunwale and wide doors greatly improve th appearance of many models.

Two Representative 1928 Cars.

The triumph of the "six" was illustrated b engines varying in capacity from 1½ to 9 litres ar in horse-power from 11 to 45. Most remarkabl however, was the perfection of some of the 16 h. cars with six cylinders, listed at a price which 1921 would have barely purchased an open fou cylinder 11·9. Two cars especially illustrate th way in which the British industry is holding its ov in a field where America once reigned unchallenge

The Arrol-Aster is the offspring of a happy unio between two famous veterans, the Arrol Johnsto

FIG. 2.



14 h.p. Lea Francis, six-cylinder, with fixed head coupé bod

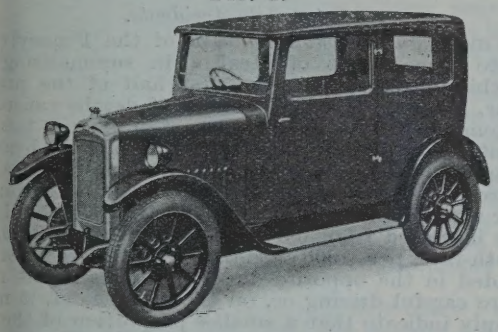
and the Aster Engineering Co. The 17/50 h.p. chas would be fair value at £700; actually it costs £4(or £495 with a three-seater body and £535 with fabric saloon. The first exceptional feature is t Enots "one-shot" chassis lubrication system, means of which one pump on the dashboard lubricat every bearing in the chassis through pipes. T springs, fitted with silent bloc shackles, need greasing. The driving position is good, although t gear and brake handles might with advantage be little closer in and the latter is slightly too n the body for the knuckles to have proper roo The driving-seat is adjustable for rake as well distance. The windscreen is in one piece, hinged the top, and has a patent locking device to hold in place; a drain leads away the water that pou

rom the lower edge during a storm, and none can nter the car. The windows of the saloon body spring p by themselves, and the blind over the rear window controllable from the driver's seat. The tubular ross-member of the frame is hollow, and exhaust ases are led through it to heat the body in winter. our brakes are worked simultaneously by the ot, and two other independent brakes by hand. he engine has single-sleeve valves and a four-speed ear-box is fitted with right-hand change. Altogether is car is a splendid achievement. These makers, parately and collectively. also manufacture a h.p. four-cylinder and two other six-cylinder chassis.

The Brocklebank 15 h.p. six-cylinder chassis is mewhat smaller. The fabric saloon body, by the akers, is fitted with single seats for the driver and s companion, and the upholstery is of real leather ith pneumatic padding. The equipment is lavish nd the coachbuilt saloon has one of the best cellulose nishes in the show. No medical man should buy a r of this class without inspecting the Brocklebank. his is the only chassis made by this firm, who believe concentrating on one design. With a two-seater dy the car costs £385, and with a Gordon England bric saloon £398.

Other medium-powered six-cylinder cars of moderate ice, in addition to those we mentioned last week,

FIG. 3.



The Triumph "Super Seven" fabric saloon.

the 16 Austin, a new-comer wh ch was unfortately too late for the show (£355), the 18 Bean (£475), 15 Hampton (£425), the 16 Rover (£410), the Standard (£330), the 18 Star (£450), the 18 Surrey 25), the 14 Talbot (£395), the 14 Vulcan (£375), 16 Waverley (£450), and the 16 Wolseley (£450). price quoted is for the five-seater touring model each case, but the doctor who prefers a coupé obtain it on these or practically any other chassis usually, a slightly higher price. Morris Motors sell a light six saloon at £350.

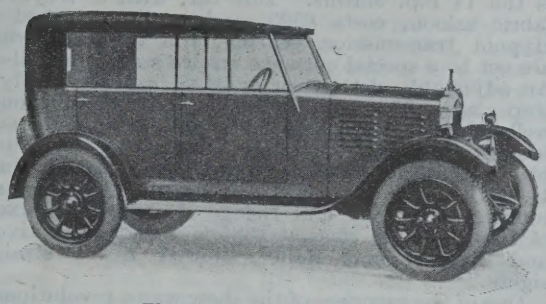
We referred last week to the excellence of the Vauxhall, of which two models are shown at £475 £495, and of the Armstrong-Siddeley, whose price markably low at £400.

Cheap Cars.

The Trojan at £125 has become a national institu-, and the saloon model at £170 is very handsome ed, though the back seats might with advantage leeper and have a greater tilt. The top is detach-. The Jowett four-seater (£145) and saloon (£170) e more leg-room than ever, and it is actually ible for a six-foot man to stretch his legs in the of one of these cars without sitting crosswise. firm were also showing a most attractive sports el at £145. The "baby" Austin is now sold at 5 and is for the first time faced with a rival, the mph Super Seven (Fig. 3), which costs £149 10*s.* four-seater, £167 10*s.* as a two-seater de luxe, £187 10*s.* and £192 10*s.* with fabric and coach- saloons respectively. The back has, if not le, at any rate reasonable room; the finish and olstery are of big-car standard, and the makers n a 55 m.p.h. maximum. Moreover, the design pes that infantile appearance which the makers nall cars find it so difficult to avoid.

The 9 h.p. Standard at £190 with a two- or four-seater body (Fig. 4), and £215 with a fabric saloon, is a decided acquisition to the small-car class. The most prominent features of this car are its big radiator and the horizontal louvres in the bonnet sides. The top of the windscreen is a little low in the closed model and the central gear lever does not come to hand as

FIG. 4.



The Standard Touring Car.

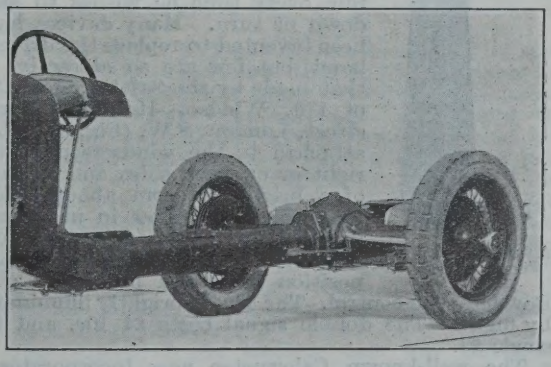
easily as it should, but these are the worst faults. The appearance is very handsome and the body is comfortable to sit in. The passenger preparing to enter the tonneau and fold himself into the small compass usually demanded by such places finds with surprise and relief that the designers have provided a deep pit, extending well under the front seats, in which there is ample room for his feet. The new 9 h.p. Clyno, which has an engine capacity of 950 c.cm., is sold for £145 as a four-seater and £160 as a saloon. It has the new pattern radiator and is an attractive car.

On the borderline of the cheap cars are the Fiat 9 two-seater at £195, the Humber 9/20 two- or four-seater at £250 (a first-class car with plenty of leg-room), the Swift 10 two- or four-seater at £220, the Rover 10 two-seater at £220, and Weymann fabric saloon with sliding top at £250, and the Riley 9 two-seater at £235. This is mentioning a few only out of very many examples.

Foreign Cars.

Study of the catalogue reveals the fact that our industry is now competing effectively with the American and matching it at nearly every point.

FIG. 5.



The new and unorthodox Austro-Daimler chassis.

The Trojan is holding its own, in this country at any rate, with even the redoubtable Ford. Last year the Erskine, a splendid little car, stood quite alone; this year it has more than one British competitor at its chassis price of £230. The new Dodge six-cylinder 25·6 h.p. chassis at £395, or £565 with a saloon or five-seater body, is a new departure for this firm, and the Commander, a Studebaker monster of nearly six litres capacity, or 36 h.p. by our rating,

comes to contest the field with Bentley, Rolls, and Lanchester. It must be admitted that no British saloon of this size is obtainable for £565. The Franklin air-cooled six with its ash frame is still unique, and the Peerless and Velie sixes and the Stearns-Knight and Little Marmon "straight eights" are new to the British market. Size for size, we are increasing our price advantage over the continental manufacturers, but a conspicuous rival in the light six-cylinder class is the 14 h.p. Mathis. This car, with a Weymann fabric saloon, costs £395, and is distinguished by Hypoid transmission gearing, the teeth of which are cut to a special curve to ensure a smooth pull-off. An adjustable cloth visor is fitted inside the body to stop glare. The 10 h.p. Mathis has a conspicuously well-finished Weymann body for £275. Renault, besides the little Monasix, were showing a huge black 45 fabric saloon that they had made to Major H. O. Segrave's order for very fast long-distance touring. Peugeot and Delage also showed "sixes" of 16 h.p. saloon class at £385 and £625 respectively, and Bugatti and Ballot showed new "straight eights."

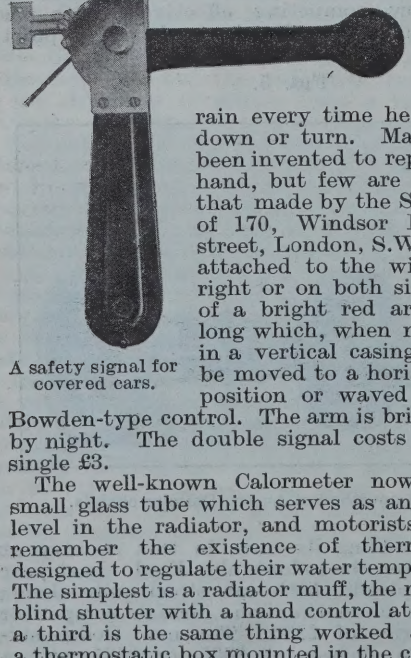
One of the surprises of the show was a revolutionary chassis on the Austro-Daimler stand called the ADR 22/70 (Fig. 5); from the radiator to the scuttle it is orthodox, but at that point the frame sweeps inwards to meet the unit gear-box, and continues back to the rear axle as a large solid tube encasing the transmission shaft. The live-axle casings are hinged and the rear springs are underneath them. The body is supported at the level of the gear-box and at three points on the tube, once by a stay passing right through this member. The advantages claimed are the saving of 3 cwt., the independent movement of the back wheels, which eliminates skidding and gives better adhesion; exceptionally good springing, a low centre of gravity, and the avoidance of torsional stresses in the body.

There were no new types of large car calling for special notice, but many well-known and excellent makes were fully represented.

Accessories.

Opponents of the saloon body have one argument that cannot be answered, that if the driver is to be protected from weather he cannot signal with his hand. Moreover, no one wants to put an arm out into pouring rain every time he wishes to slow down or turn. Many devices have been invented to replace the driver's hand, but few are so attractive as that made by the Safety Signal Co., of 170, Windsor House, Victoria-street, London, S.W. (Fig. 6). It is attached to the windscreen at the right or on both sides and consists of a bright red arm about a foot long which, when not in use, hangs in a vertical casing and which can be moved to a horizontal or upright position or waved by means of a Bowden-type control. The arm is brightly illuminated by night. The double signal costs £4 10*s.* and the single £3.

FIG. 6.



A safety signal for covered cars.

The well-known Calormeter now incorporates a small glass tube which serves as an indicator of the level in the radiator, and motorists will do well to remember the existence of thermostatic devices designed to regulate their water temperature in winter. The simplest is a radiator muff, the next is a venetian blind shutter with a hand control at the driving seat, a third is the same thing worked automatically by a thermostatic box mounted in the circulatory system (Smith and Sons), and the most elaborate of all is a thermostat that actually controls the flow of water.

A dual windscreen-wiper, clearing two contiguous areas, is an improvement on the single type; in this sold by S. Smith and Sons at £2 5*s.* the two arms are worked from one driving box.

Jacking is facilitated by the provision of the Enots hydraulic jack (45*s.*) of a long handle by which the operator can raise the head to the required height under the axle without circling; also by the Salisbury Jack Guide, a runner fitted under each spring and parallel to it. The jack head, of a special design, is linked on to the runner and pushed along it with the jack handle until it reaches the desired position.

All the well-known makers of sparking plugs exhibited, and Lodges especially catered for particular types of engines, with their HD model for Daimler, TB for Buicks, AF for Fords at 6*s.* 6*d.*, 5*s.*, and 4*s.* respectively. Dunlops held their own against a real inrush of foreign competitors with their "Buttress" Triple Stud" balloon and medium pressure tyres.

The show was a striking revelation of the enterprise and creative genius of motor-car manufacturers in general and of British makers in particular.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Automobile Accidents.

THE *Vital Statistics Bulletin* of the Pennsylvania State Department of Health, in summarising the morbidity returns for the first half of the present year, remarks that the number of deaths caused by automobiles continues to rise steadily. A table is printed, however, to show that "despite the headline characteristics associated with automobile fatalities there is an encouraging element in the background. For whereas the mortality-rate per 100,000 population has increased from 0·3 in 1906 to 18·4 in 1926, the death-rate per 1000 registered motor vehicles has tended in the opposite direction. This might mean more careful driving or, on the other hand, it might simply indicate that a smaller proportion of the cars are kept on the road than formerly. The present record of one person killed each year for every 150 vehicles registered is shocking enough.

A Public Health Congress.

About 160 speakers have agreed to address the fifty-sixth annual meeting of the American Public Health Association to be held at Cincinnati from Oct. 17th to 21st. Dr. Charles V. Chapin, the President, will speak on Science and Public Health. A discussion on the highly controversial subject "Has Prohibition Promoted Public Health?," will be opened by Prof. C.-E. A. Winslow, of Yale University, and continued by Dr. Louis I. Dublin, statistician of the Metropolitan Life Insurance Company, Dr. Haven Emerson, of Columbia University, and Dr. Matthias Nicoll, jun. The Health Commissioner of the State of New York, Dr. Paul F. Orr, is to give an Epidemiological Study of Malta Fever in Michigan. Among other distinguished speakers is Dr. Pierre Boudreau, of the Health Section of the League of Nations, and the meeting promises to be of unusual interest.

New Psychiatric Institute for New York.

Governor Smith, to whose official backing is largely due the successful financing of the new Psychiatric Institute, laid the foundation-stone on Sept. 19. There will be 20 stories, of which the lower ten will be occupied by a hospital in connexion with the Institute. Here students of the College of Physicians and Surgeons will have an opportunity to study the early symptoms and treatment of mental disease. The upper stories will be largely devoted to research, there will, however, be accommodation in the Institute proper for cases of special scientific interest. Courses of instruction will be offered to physicians, social teachers, social workers, and welfare officers.

Correspondence.

"Audi alteram partem."

THE USE AND MISUSE OF DENTAL SKIAGRAMS.

To the Editor of THE LANCET.

SIR,—Permit me to draw your attention to a practice which appears to be growing and is, I venture to think, prejudicial to all concerned. It is this. A doctor, thinking that the condition of his patient's teeth may have a bearing on his illness, sends him to a radiographer of his own choosing. On the strength of his own or the radiographer's interpretation of the resulting radiograph, often not too clear, he makes a diagnosis, possibly prescribes treatment, and either requires the patient's own dentist to carry it out or very frequently sends him to someone else of his own selection. Surely this is wrong.

Dental radiograms are a very valuable aid to diagnosis, but only an aid, and no substitute for clinical examination. They are often invaluable in revealing unsuspected trouble, more often still in affording ocular and convincing proof of what the dentist already knows or suspects; but, on the other hand, there may be serious sepsis without there being any signs of it in the radiogram; their negative evidence cannot be relied upon. Moreover, to be of value they must be really good, and to produce good dental films requires considerable practice. With certain brilliant exceptions the dentist who takes his own usually attains to a higher level of perfection than the general radiographer. Far too many reports are made upon skiagrams so imperfect that no safe deductions can be drawn from them. Having obtained good films they must be correctly interpreted, often no easy matter, and here again the dentist is more likely to be successful than the medical man or the radiologist in whose report the doctor usually puts implicit faith.

As examples of the gross errors easily made I may mention a case where a patient was recently told by a doctor that an upper wisdom tooth was diseased and must come out, the "tooth" in question being the coronoid process of the mandible; and the frequent condemnation of lower premolars as the subject of chronic sepsis, by reason of the proximity of the inferior dental foramen to their roots. It is obviously unwise to depend upon the shadow for diagnosis and entirely ignore the substance. No dentist would rely solely upon radiograms apart from clinical examination and the clinical history. Were he limited to one or the other he would certainly choose a careful clinical examination. It is not uncommon for a patient to come to a dentist with films taken at the request of his doctor and instructions that certain teeth are septic and to be removed, while others much worse are passed unnoticed. It is not only unprofessional and discourteous to ignore the patient's own dentist, but shortsighted; because, if a careful man, he will have a recorded history of the mouth which may prove of the utmost value.

The reasons why he is so often ignored by the doctor when a diagnosis is to be made would appear to be that the doctor mistrusts dentists in general (or, possibly with good reason, that one in particular) while he overrates skiagrams as a source of accurate and complete information, and fails to realise that their interpretation is a matter where the knowledge and experience of the dentist and his clinical findings are of the utmost value, with the assistance of the radiogram in case of difficulty. Surely the correct course is to refer the patient in the first instance to his own dentist, if he has one, for a report, with skiagrams, on the condition of the mouth. If, for any reason, this report should not inspire confidence, a second opinion should be sought. In this way the patient's interests would be served and no one would have cause to complain. The facts are that the average doctor has very little knowledge of teeth, and the average dentist has very little knowledge of general pathology, so that only by their close coöperation can the patient derive the maximum benefit.

I am, Sir, yours faithfully,

Harley-street, W., Oct. 12th, 1927. J. H. BADCOCK.

PARAPLEGIA IN HODGKIN'S DISEASE.

To the Editor of THE LANCET.

SIR,—In connexion with the three articles in THE LANCET of Oct. 15th (pp. 806–810), perhaps I may be permitted to draw attention to a case of Hodgkin's Disease with Paraplegia, by Dr. J. Carslaw and Dr. J. S. Young, in the current number of the *Glasgow Medical Journal* (1927, cviii., 193). In their case there was a diffuse growth of fibrocellular tissue, comprising a small proportion of large cells with irregular, hyperchromatic nuclei, in the extradural space of the dorsal region.

As far as I know no involvement of the extradural space has yet been noted in cases of Hodgkin's disease in which during life there has been herpes zoster, but perhaps this is because in such cases the vertebral canal has not been examined at post-mortem examinations. Personally, I used to think that the occurrence of herpes zoster in cases of Hodgkin's disease was due to arsenical treatment, but it may well be that in some cases it has been a result of involvement of the posterior roots (with their ganglia) of spinal nerves in the lymphogranulomatous process. Incidentally I note that these authors speak of "Hodgkin's sarcoma" after J. Ewing. Surely, the term "Hodgkin sarcoma" would be better, as Hodgkin certainly did not distinguish a Hodgkin sarcoma from a Hodgkin granuloma, though now both may well be named after him (in his honour).

I am, Sir, yours faithfully,

London, W. 1, Oct. 15th, 1927. F. PARKES WEBER.

SUBSTITUTES FOR WINDOW GLASS.

To the Editor of THE LANCET.

SIR,—I have read with great interest the comment in THE LANCET of August 6th, p. 316, on the report of the Council on Physical Therapy of the American Medical Association on various materials advertised as pervious to ultra-violet rays. Your coöperation and support as evidenced by the publicity given this report and previous reports of the Council in your valued journal is deeply appreciated. Such coöperation and support of the Council in its great task will materially hasten the day when physical therapy will be on as sound a basis as pharmacotherapy is to-day.

In view of the undoubtedly good influence of such publicity it is unfortunate that in the comment on the report on window glass substitutes the writer should apparently not thoroughly understand the purposes of some of the experimental work that was done by the Council. In the last paragraph of your article it is stated that in view of the well-established fact that it is the shortest ultra-violet rays of sunlight that make heliotherapy valuable in the prophylaxis and cure of rickets, it seems hardly necessary to have tested the value of these glass substitutes biologically. The object of the biologic test performed on the materials under consideration has been apparently understood imperfectly.

The object of the biologic test was threefold: (1) to determine whether sufficient ultra-violet energy is present in winter sunshine in urban centres to warrant the use of materials of this sort for glazing windows; (2) to determine the relative value of the materials tested as transmitters of the anti-rachitic rays of the sun; and (3) to determine the antirachitic effect of winter sunlight filtered through these materials as compared with that of ultra-violet light from an artificial source.

I am, Sir, yours faithfully,

H. J. HOLMQUEST,

Chicago, Oct. 6th. Secretary, Council on Physical Therapy.

THE POSITION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

To the Editor of THE LANCET.

SIR,—The Council of the Royal College of Surgeons of England has just published the result of the poll of the Fellows of the College on the question of the admission of Members to some representation on the Council. The voting paper was sent to 1850 Fellows; 846 voted No, 234 voted Yes; 770 Fellows did not vote. Unfortunately, and unfairly, I contend, the Council issued with the voting paper a definitely biased and *ex parte* statement of the Members' case.

It is remarkable that 770 Fellows did not vote. Also it should be noted that there are about 600 Fellows in the metropolitan area.

I am, Sir, yours faithfully,
REDMOND ROCHE.

Eccleston-square, S.W., Oct. 16th, 1927.

HOSPITALS AND MOTOR-CAR ACCIDENTS.

To the Editor of THE LANCET.

SIR,—May I trespass upon your columns to ask the secretaries of hospitals throughout the country who can provide statistics as to the number of motor-car accident cases treated (with, if obtainable, the average length of stay) to send them to me, if possible, by the end of the present month. I am endeavouring to obtain statistical proof of the circumstances which have been alluded to so frequently in your columns of late.—I am, Sir, yours faithfully,

H. W. BURLEIGH,
Secretary and General Superintendent.

Hospital for Epilepsy and Paralysis, Maida Vale, W.,
Oct. 17th, 1927.

MISLEADING QUALIFICATIONS.

To the Editor of THE LANCET.

SIR,—By an old-standing convention (adopted by makers of dictionaries and works of reference) Fellowship of the Royal College of Surgeons of England is denoted by the letters F.R.C.S., and Fellowship of the Royal College of Physicians of London by the letters F.R.C.P. Fellowship of other colleges, according to the same custom or convention, should be indicated by the addition of letters distinctive of the college to which the Fellow belongs. Those who do not conform to this convention are therefore liable to be judged ignorant if not, indeed, anxious to appear other than what they are.

But there is no existent convention by virtue of which any one who appends M.D. to his name is to be supposed doctor of medicine of any particular university. M.D. means doctor of medicine; F.R.C.S. means Fellow of the Royal College of Surgeons of England. I am, Sir, yours faithfully,

Oct. 14th, 1927. F.R.C.P.

*** More authority is needed for the closing "ipse dixit."—ED. L.

PAYMENT TO HOSPITALS FOR MOTOR ACCIDENTS.—Motor accidents are causing a serious increase of the waiting list at the Norfolk and Norwich Hospital, besides heavy expenditure. Motor insurance companies, it is stated, have resisted liability for payment of the hospital costs of such accidents on the ground that hospitals are voluntary institutions, and are therefore unable to sustain a claim. A report shows that in the first week of September there were 35 cases of injury in motor accidents in the hospital, and that their length of stay was considerably above the average. At a meeting of the hospital authorities on Oct. 8th it was pointed out that a private practitioner to whose surgery a motoring victim was taken could send his bill to the insurance company, and that the hospital could put itself in the same position as a private practitioner by sending all its motor cases to the new paying ward which would be opened early in the new year.

Obituary.

MAJ.-GEN. SIR WILLIAM GRANT MACPHERSO K.C.M.G., C.B., LATE A.M.S.

WE regret to announce the death of Sir Will Macpherson, the editor-in-chief of the official "Med History of the War," and a familiar person to med men as a great soldier-doctor. He died on Satur last at his house in Evelyn Gardens, Kensington the age of 69.

Macpherson was the son of the Rev. W. Macpher of Kilmuir Easter, Ross-shire, where he was b in 1858. He was educated at Fettes College, b one of the original band with whom that school opened in 1870. He proceeded to the University Edinburgh, where he graduated in the first insta in high classical honours, being university scholar in Greek, but later he turned to medicine, and in 1882 graduated M.B., C.M. Edin. After taking out post-graduate courses at the Universities of Leipzig and Tübingen, he entered the Royal Army Medical Corps with credentials of an unusually high order, so that his success was immediately predicted and opportunities for special service c readily to his hand. In 1892 he was in medical ch of Sir Euan Smith's mission to Fez, and he filled same position in Sir Arthur Nicolson's missio Morocco City. In such capacities he made a mar himself alike as a doctor and as a man of the world previous to the outbreak of the European Wa career formed a series of special duties in South A Panama, and Cuba, while in 1904, having rece the C.M.G., he was appointed senior medical o to the North China Command. This post he permitted to select for himself in response flattering suggestion that he should go wher could be most useful. He chose the China app ment because it would bring him near the scen the impending struggle between Russia and Ja with the result that he was attached during the R Japanese War to the Japanese Army in the saw a great variety of service, while his pers work was recognised by two Japanese decorat The experience gained in these several ways o sides of medical organisation was used by immediately afterwards in Geneva, where he was of the British plenipotentiaries at a conferenc the revision of the Geneva Convention, and in and for the next four years, he was attached t general staff A.M.S. In 1910 he was appo P.M.O. at Malta, and after holding this positio one year he was transferred for three years t

SIR WILLIAM MACPHERSON.

taff College at Quetta, an appointment which he as holding previous to the outbreak of the European ar.

The beginning of hostilities found him in high osition at the War Office, and it became his duty to operate with Sir Alfred Keogh in improvising mediately the medical activities of our Army, and is on an unparalleled scale of magnitude as the mbers of the troops grew with bewildering rapidity d the areas of fighting were multiplied. The ficial history of the war, for which Macpherson terwards became responsible as editor-in-chief, ows how wide and various was his own personal are in the many and critical circumstances where e prompt availability of medical measures formed essential feature in the conduct of the war. As rector of Medical Services in the First Army, as eputy Director-General, and later as Director of edical Services to the British Forces in Macedonia, acquitted himself with the highest distinction, ing mentioned in dispatches nine times and receiving e C.B. in 1915 and the K.C.M.G. in 1918. But he ll be remembered especially for his fine accomplishent in compiling and freely contributing to the Medical History of the Great War," and organising issue in an authoritative and convenient form. liberately limited, under Treasury conditions, to volumes, this history forms a record, as far as ssible in narrative form, of the chief features in medical services of the United Kingdom, in risons overseas, and with the Expeditionary rces in the various theatres of war during the years 4–18, and in subsequent periods when connected idents occurred of historic interest or importance. r readers know the care exercised by the editorchief and his collaborators both in the selection material and the proportionate space of the various pters, for the work, as it appeared, has been freely iewed in these columns. It is sufficient to say that object of the History, as stated in Macpherson's eral preface, was well carried out within the essary limitations; a consecutive medical story the war was presented in an accessible form, for ch the obvious sources of information have been wn upon, while much material buried in masses war diaries, administrative files, and official uments has been included, verified, and collated, that its significance emerges in relation to the eral narrative.

he time and leisure which Macpherson obtained retirement from the Army, when not taken up his official literary labours, were amply filled with lic work. He rendered active assistance to the ish Medical Association, being for five years a esentative on the Council of the R.A.M.C., for years a member of the Naval and Military Comee, a member of the Committee on the Expansion he Royal Army Medical Services in cases of onal emergency (1921–23), of the Committee on Royal Commission on the Superior Civil Service India (1924–26), and chairman of the Special mittee on Tests for Drunkenness. Further, to editorial work of the *British Medical Journal* he ered valuable help as a writer and reviewer. his pen was as skilled as his knowledge wide, and THE LANCET was also on many sions indebted to Macpherson for help and ce.

rsonally, Macpherson was a striking example of arming man, to use a hard-worked epithet, while slightest acquaintance with him revealed that ttractive manner was the least of his gifts. His learning and his hard experiences had left him ordinarily modest, but his capacity was there e used when needed. Always courteous and pathetic, he endeared himself to a large circle iends outside official and professional relations; as a genial host and a versatile athlete. As an rgraduate he had been a distinguished boxer gymnast; he played polo and hunted and raced e various stations to which responsible duties l him, and later in life he became a keen golfer. In this connexion his gratification was great when the R.A.M.C. won the Army Championship Cup at St. Andrews last year. A series of honours fell to him in the natural course of events in addition to those we have already mentioned. He was a Companion of the Legion of Honour and of the Crown of Italy, received the Distinguished Service Medal of the U.S.A., and the University of Edinburgh made him an LL.D. in recognition alike of his distinction as a scholar and of his national work.

Macpherson was married first to Miss E. A. Clunas, daughter of Mr. J. Clunas, of New Orleans, who died in 1907, and three years later he married Miss G. E. Doran, daughter of General Sir John Doran.

WILLIAM CAMERON MACAULAY, M.B. LOND.

Dr. Cameron Macaulay was the second son of Bryce Johnston Macaulay, headmaster of Wishaw Public School, Lanarkshire, and was born in 1869. Educated at Wilson Grammar School, Camberwell, he was obliged by straitened family circumstances to begin earning his livelihood at the early age of 17. He became a teacher, held various masterships, and in 1895 he graduated as Bachelor of Arts in the University of London with honours in English. For another three years he remained in the teaching profession, being an assistant master at the Westminster City School and tutor in early and mediæval English for the examinations of the University of London. But in 1898, at the age of 30, he entered the Middlesex Hospital as first entrance scholar, and began a brilliant career as medical student. He secured almost every scholarship and prize; thus in one year, 1904, he won the John Murray gold medal and scholarship, the second Broderip scholarship, the Governor's prize, the Leopold Hudson prize, and the Hetley Clinical prize. In the intervals of strenuous medical study he found time to continue teaching in English, and for several years also he held the post of demonstrator of chemistry at the Hospital Medical School. In 1903 he graduated as M.B. Lond., and after holding the resident obstetric appointment at the Middlesex settled down in practice at Brixton, where he worked until within a month of his death, save for the period of the war. An ardent Territorial, he was second in command of the 2/5th London Field Ambulance from its formation to its disbandment. He saw active service in France, Salonika, Macedonia, Egypt, Palestine, and Syria, and was mentioned in dispatches by General Allenby for gallant and distinguished services in the field.

Mr. G. Gordon-Taylor, to whom we are indebted for these biographical details, writes as follows of Dr. Macaulay's work as a practitioner: "Circumstances prevented him from taking up consulting work, and his brilliant academic career was therefore not crowned by a staff appointment, but he faithfully, ably, and assiduously served his patients in the south of London. He had a dignified and impressive appearance, and although the Latin word *gravitas* is perhaps most descriptive of him, to use the words of the younger Pliny it might well be said of Cameron Macaulay: *Et dignitate personæ et exempli raritate et iudicii magnitudine insignis.*"

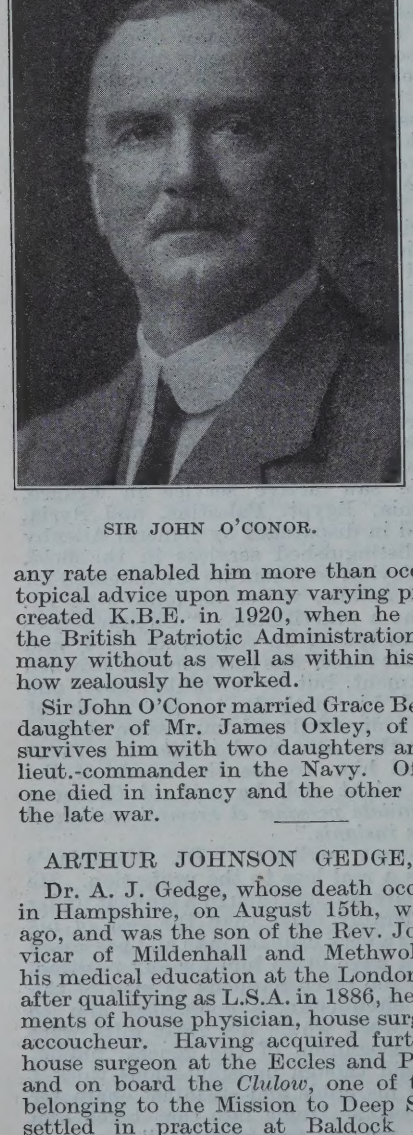
Mr. Victor Bonney writes: "Dr. Macaulay's premature death is a real loss to the profession. He entered his calling late, so that though a student under me, he was considerably older than the rest of his classmates. He was a very brilliant man and possessed ability which would have fitted him for any position, however high. As too often happens to men of the greatest promise, circumstances compelled him to take up a line of work where his great gifts were hidden from the recognition of the general public. That he did splendid though unostentatious work I can vouch for, and his noble and steadfast character enabled him to meet the tragic fate that befell him with extraordinary courage and fortitude."

Dr. Macaulay's final illness was treated at his old hospital where he was surrounded and looked after by his old friends and class-fellows, commanding the

admiration and respect of all who worked to try to save him. He is survived by a widow and one son, Dr. H. M. Cameron Macaulay, who is deputy county medical officer of health for Middlesex.

SIR JOHN O'CONOR, K.B.E., M.D., B.CH. DUB.

John O'Cônor was born at Carrick-on-Shannon in 1863, the son of Mr. Abraham O'Conor of that place, and received his medical education at Armagh and Trinity College, Dublin, where he was a member of the Fifteen and stroke of the Eight. He graduated in medicine in 1886, proceeding to the doctorate in 1890, and was for three years resident surgeon at the Royal Hospital, Portsmouth, but in 1890 proceeded to Buenos Aires, having been appointed one of the resident medical officers at the British Hospital. Four years later he became senior medical officer, and from that institution have emanated the many communications on surgery, dietetics, and hospital administration which he made to the medical press. These communications were largely in the form of letters, in which particular points were taken up or brief summaries were given of personal experience along certain ranges of diagnosis and treatment, although longer articles were occasionally published from his pen, such as a recent one in our columns upon cholelithiasis. Much of his writing was of practical value, and if his communications suffered in one respect from the desultory nature of their appearance, this method at any rate enabled him more than occasionally to give topical advice upon many varying problems. He was created K.B.E. in 1920, when he was chairman of the British Patriotic Administration Committee, and many without as well as within his profession know how zealously he worked.



SIR JOHN O'CONOR.

Sir John O'Conor married Grace Beatrice Richmond, daughter of Mr. James Oxley, of Frome, and she survives him with two daughters and a son who is a lieut.-commander in the Navy. Of two other sons, one died in infancy and the other on service during the late war.

ARTHUR JOHNSON GEDGE, M.R.C.S. ENG.

Dr. A. J. Gedge, whose death occurred at Havant, in Hampshire, on August 15th, was born 63 years ago, and was the son of the Rev. John Denny Gedge, vicar of Mildenhall and Methwold. He received his medical education at the London Hospital, where, after qualifying as L.S.A. in 1886, he held the appointments of house physician, house surgeon, and resident accoucheur. Having acquired further experience as house surgeon at the Eccles and Patricroft Hospital and on board the *Clulow*, one of the hospital ships belonging to the Mission to Deep Sea Fishermen, he settled in practice at Baldock in Hertfordshire, but 24 years ago moved to Havant, where the remainder of his life was to be spent. Dr. Gedge strongly advocated abstention from alcohol and was medical officer to the local Tent of Rechabites. He was a faithful churchman; a number of his patients and friends are arranging to place a window to his memory in the Parish Church, Havant. He will be much missed in local archæological circles for his sound antiquarian knowledge, which was always at the service of the Hayling Island Field Club. It was largely due to his private representations and to an appeal which he drafted that Portchester Castle was scheduled as an historic monument and saved from further dilapidation, and he was keenly interested in the excavation of the newly discovered Roman villa on Holt Down, between Horndean and Peters field.

"It has been one of the greatest privileges of my life," writes a medical colleague, "to know Arthu Johnson Gedge for 20 years. During that period never heard him say an unkind word of anybody His tastes were numerous. Archæology, antiques folklore, and country life being perhaps the principa things in which he interested himself apart from h professional reading, which had been wide and varied His keen sense of professional honour was such tha all his colleagues trusted him perfectly. He wa consistently cheerful during a lifetime of man difficulties (never referred to by himself); his patient loved and trusted him absolutely, and he has le behind him a fragrant and beautiful memory."

Dr. Gedge left a widow, two sons and one daughte

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a Congregatio held on Oct. 15th the following degrees were conferred:

M.D.—J. C. N. Harris (by proxy) and L. P. Lockhart.
M.B. and B.Chir.—H. J. Burrows, N. H. R. Hatfield, G. Chandler, and M. S. Dewhurst.
M.B.—A. C. Copley.

At recent examinations the following candidates w successful:—

Diplomas in Public Health and in Hygiene.—Part II.: L. A. Anderson, H. M. Ayres, Albert Gilbert, H. M. Osm M. H. M. Ragab, K. N. Segal, George Shehata, H. Sin Mary Y. M. Stevenson, and H. C. Wilkinson.

UNIVERSITY OF GLASGOW.—The following degr were conferred on Oct. 17th:—

D.Sc.—John Glaister, M.D.
M.D.—With honours: Amy M. Fleming and Georg Murdoch. *Ordinary Degree:* A. M. Scott.
M.B., Ch.B.—With Honours: W. A. Mackey, Margaret Thomas, W. S. Hodghton, A. K. Hill, and J. M'K. Brews *With Commendation:* A. W. Fraser, Matthew Bowm Margaret G. Crockett, G. H. Gibson, L. J. Lang, Rol M'Whirter, W. B. Kyles, John Fleming, Thomas Johnsto S. A. Maclean, H. P. Goldman, and L. L. Hurw *Ordinary Degree:* F. V. Adams, James Agnew, R. W. Agn Frances W. Anderson, W. W. Ballardie, Hugh Bankhe John Baxter, George Bryden, R. MacN. Buchanan, J. S Burnett, J. B. Cadas, J. M. Clow, Thomas Craig, Isabella Currie, John Darling, H. M. Davie, I. M'C. C. Dewar, J. Drummond, J. E. Dunn, L. C. Durie, C. A. Ferguson, H Ferguson, J. B. Fulton, R. D. Gilchrist, J. M'M. Gils J. S. Graham, J. C. Gunn, Thomas Hamilton, Da Hannah, Alexander Hart, J. A. Houston, William Hun Philip Jacobs, Robert Jamieson, R. S. Kennedy, W. M Ker, G. K. Kirkland, William Kirkwood, Annie La Malur Lakshmiamma, J. H. B. Livingston, Alexa M'Crorie, Allan Macdonald, James MacDonald, Will MacDonald, C. M. M'Intyre, Charles M'Kay, J. L. M'N H. D. Manderson, A. C. Morrison, Margaret Mulv Jessie W. Ogilvie, R. A. S. Peacock, Elizabeth Pollock, T. A. Pratt, A. R. Reid, J. B. Rennie, Da Robertson, J. K. Roger, B. B. Rosenheim, W. F. Se A. R. Shaw, James Simpson, H. S. Strachan, W. B. Sut land, George Swanson, Jean W. Symington, Annie Thompson, T. H. S. Tizzard, Matthew Tytler, Isabell Wiese, W. H. Wilkie, A. D. Williamson, Elizabeth R Wilson, J. W. Wilson, W. G. Wilson, and Elizabeth Young.

William A. Mackey gains the Brunton Memorial Prize awa to the most distinguished Graduate in Medicine of 1927.

Margaret W. Thomas gains the West of Scotland R.A. Memorial Prize, awarded to the candidate with the hig aggregate marks in Medicine, Surgery, and Midwifery in the M.B., Ch.B. Examination, 1927.

ST. THOMAS'S HOSPITAL DINNER.—The students' dinner will be held at St. Thomas's House, Lam Palace-road, on Friday next, Oct. 28th, at 7.30 for 8 Sir Charles Ballance in the chair.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a quarterly meeting of the Council on Oct. 13th, Sir Berkeley Moynihan, the President, in the chair, it was reported that the vacancy in the Council occasioned by the death of Mr. Thelwall Thomas would be filled at the election of members of Council in July next. The President further reported that a Sir Gilbert Blane gold medal had been awarded to Surgeon-Lieut. Commander Allan Watt McRorie, M.B., R.N.—Mr. C. J. S. Thompson, M.B.E., formerly director of the Wellcome Historical Medical Museum, was asked to act as honorary curator of the historical section of the museum (including surgical instruments and appliances), in succession to the late Mr. Alban Doran, F.R.C.S., for the ensuing year.

The result of the recent poll of the Fellows about altering the constitution of the College was announced as follows: The question asked was, "In your opinion is it desirable that members of the College should have direct representation upon the Council?" The voting was, "No," 846; "Yes," 234; majority against, 612.

The annual report of the Council, 1927, was approved and adopted, and will be placed before the Fellows and Members at the annual meeting on Thursday, Nov. 17th.—The President reported that Sir Holburt Waring had consented to deliver the next Hunterian oration, and it was decided to celebrate the bicentenary of the birth of John Hunter on Feb. 14th, 1928, either by bringing forward by one year the usual Hunterian festival, or in some other manner.

The under-mentioned diplomas were conferred by the Council:—

F.R.C.S.—Nils L. B. V. Eckhoff, M.R.C.S., L.R.C.P., Cape and Guys.

M.R.C.S.—G. M. Phadke, University College.

L.D.S.—M. Abrahamson, Middlesex and Royal Dental Hosps.

The *Thomas Vicary Lecture* will be delivered in the theatre of the College on Thursday, Nov. 3rd, at 5 P.M., by Dr. George Parker, whose subject will be the Early Development of Hospitals.—The *Bradshaw Lecture* will be delivered on Thursday, Nov. 10th, at the same place and hour by Sir Cuthbert Wallace. It is entitled Enlarged Prostate: A Review. Members of the profession who are not Members or Fellows of the College will be admitted to these lectures on presentation of their private visiting cards.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At examinations held recently the following candidates were granted the diploma in Public Health:—

Hassan Suhrawardy, William B. Moore, Angus E. W. McLachlan, James O. Hamilton, Jeannie Kean, Charles K. Robertson, John Douglas, Andrew McFarlane, and Archibald Gardiner.

The following candidate passed Part I.:—

Eleanor B. Bone.

THE Prix Hollandais, awarded for the best work of the year in physical anthropology, has gone to Miss Dorothy A. E. Garrod, whose volume on the Later Palæolithic Age in Britain was published in 1926 by the Clarendon Press. The prize is of the value of 7000 French francs, say £57.

UNIVERSITY COLLEGE HOSPITAL DINNER.—The annual dinner of past and present students was held at the Hotel Cecil on Oct. 14th, when Sir George Blacker presided over a large gathering. In the course of his report on the past year, the Dean, Dr. A. M. H. Gray, mentioned that the centenary of the medical faculty of University College fell in 1928. He said that, with its new obstetric and aural hospitals, University College Hospital now possessed 500 beds, and in buildings and equipment was second to no hospital in London. Among the investigations carried out in the medical school during the past year he mentioned the synthesis of thyroxin by Dr. C. R. Harington, a notable achievement in biochemistry. He also referred to the severe loss which the hospital had recently sustained in the deaths of its chairman and vice-chairman, Sir Ernest Hatch and Lord Oranmore and Browne.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—The annual meeting was held on Oct. 14th, Sir William Taylor was elected President in succession to Sir James Craig, whose term of office had expired. Sir William Taylor is Regius Professor of Surgery in the University of Dublin, and is one of the surgeons to Sir Patrick Dun's Hospital; he has been a Fellow of the Academy since 1898. The following were elected on the General Council: Sir James Craig, Mr. R. C. B. Maunsell, Sir John Moore, Dr. T. G. Moorhead, Dr. G. E. Nesbitt, and Prof. R. J. Rowlette. The following were elected presidents of the several sections: Medicine, Dr. G. E. Nesbitt; surgery, Mr. Andrew Fullerton; pathology, Mr. T. T. O'Farrell; obstetrics and gynæcology, Dr. G. FitzGibbon; anatomy and physiology, Prof. J. M. O'Connor; State medicine, Dr. J. W. Bigger.

UNIVERSITY OF LONDON: *University College Hospital.*—Three lectures on the History of Medicine (illustrated by lantern slides) will be delivered by Dr. Charles Singer on Mondays, Nov. 7th, 14th, and 21st, at 4.15 P.M., in the large lecture theatre No. 1, of the Medical School. The subjects will be respectively Syphilis, Influenza, and Typhoid Fever, and the lectures will be open to all medical students of the University.

UNIVERSITY OF OXFORD.—The new School of Biochemistry will be opened to-day (Friday), Oct. 21st, by Viscount Cave, Lord Chancellor of England and Chancellor of the University. The ceremony will be held in the Sheldonian Theatre at 3.30 P.M., after which, at about 4 P.M., the Chancellor will proceed to the new department which will be opened for inspection.

BROADCASTING AND PUBLIC HEALTH.—On Oct. 5th Dr. G. F. Buchan, ex-president of the Society of Medical Officers of Health, broadcasted an address from 2 LO on Health and Education. This is said to be the first time that a medical officer of health has broadcasted in this country.

INTERNATIONAL OTO-RHINO-LARYNGOLOGICAL CONGRESS.—The provisional programme has now been issued of this Congress to be held at Copenhagen from July 29th to August 1st, 1928, under the presidency of Prof. E. Schmiegelow. The Secretary-General is Dr. N. R. Blecvad, 3 Nytorv, Copenhagen, K.

AN ASTHMA RESEARCH COUNCIL.—A new organisation has been formed called the Asthma Research Council. The Earl of Limerick and Lord Greenway are to act as president and vice-president respectively, and the honorary secretary is Capt. F. L. M. Boothby. The offices are at 12, Bedford-street, Strand, London, and the Council is stated to be "anxious to get in touch with all asthma sufferers."

UNIVERSITY OF MANCHESTER.—Dr. R. B. Wild, who has recently retired from the Leech Chair of Materia Medica and Therapeutics, has made a gift of £250 for the endowment of a prize in pharmacology. Prof. J. S. B. Stopford has been appointed as representative of the University on the General Medical Council; Mr. C. A. McGaughey, M.R.C.V.S., has been appointed assistant lecturer and Dr. E. St. G. Gilmore demonstrator in bacteriology; and Dr. H. C. Sheehan has been appointed demonstrator in pathology.

DONATIONS AND BEQUESTS.—The late Baroness Marie von Schröder, of The Rookery, Worleston, Nantwich, left £500 each to the Nantwich Cottage Hospital and the Crewe Cottage Hospital—Mr. Joshua Fearnside Sinclair, of Otley, solicitor, left £500 to the Otley and District Nurses' Home, £300 to the Otley Ladies' Sick Nursing Visiting Society, and £1000 to the National Children's Home and Orphanage.—Mr. C. Collins, of Edgbaston, left the whole of his property, £13,963, to his wife for life, and on her death, after several legacies, the residue between the General Hospital, Queen's Hospital, Children's Hospital, General Dispensary, Women's Hospital, and the Eye Hospital, Birmingham, and the Blind Asylum, Edgbaston.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Monday, Oct. 24th, at 5 P.M., at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, Mr. Herbert Paterson will deliver a lecture entitled Surgical Hints. On the same afternoon, at 2 P.M., Mr. J. B. Hunter will give a surgical clinical demonstration at the Royal Northern Hospital, and on Tuesday, the 25th, at 3 P.M., there will be a medical clinical demonstration at the same hospital, by Dr. Bruce Williamson. At the Central London Ophthalmic Hospital, on Thursday, Oct. 27th, at 4 P.M., Mr. Cunningham will give an ophthalmic clinical demonstration. The lecture and the demonstrations will be open to members of the medical profession without fee. From Oct. 24th to Nov. 5th, there will be a special course in ophthalmology at the Royal Eye Hospital, with demonstrations daily at 3 P.M. Courses in the following subjects will be given during November: Medicine, Surgery, and the Specialties, at the Hampstead General Hospital, 4 to 6.30 P.M., Oct. 31st to Nov. 12th; a similar course at the London Temperance Hospital, Nov. 21st to Dec. 3rd; Medicine, Surgery, and Gynæcology at the Royal Waterloo Hospital, afternoons and some mornings, Nov. 14th to Dec. 3rd; Diseases of the Chest at the Brompton Hospital, all day, Nov. 7th to 12th; Neurology, at the West End Hospital for Nervous Diseases, Nov. 21st to Dec. 17th, daily at 5 P.M.; Proctology at St. Mark's Hospital, Nov. 28th to Dec. 3rd; Urology at St. Peter's Hospital, afternoons, Nov. 14th to 26th; and Venereal Diseases, at the London Lock Hospital, afternoons and some evenings, Oct. 31st to Nov. 26th. Copies of all syllabuses are obtainable from the secretary of the Fellowship at 1, Wimpole-street, London, W.

Dr. Joseph Priestley, on his retirement after 32 years' service as medical officer of health for Lambeth, is to receive a presentation from fellow practitioners of the locality. The ceremony will take place on Thursday, Oct. 27th, at the town hall.

HANBURY MEMORIAL MEDAL.—The gold medal from time to time awarded in memory of Daniel Hanbury for "high excellence in the prosecution or promotion of original research in the Chemistry or Natural History of Drugs" has been given this year to Mr. T. A. Henry, D.Sc., Director of the Wellcome Chemical Research Laboratories, London. Since 1881 there have been 21 recipients of the medal, seven of whom were British and six German. The trustees of the fund are the Council of the Pharmaceutical Society of Great Britain.

PURITY OF ICE-CREAM.—A deputation representing the Ice-Cream Association of Great Britain and Ireland waited on officials of the Ministry of Health on Oct. 11th and suggested that a legal definition of ice-cream should be laid down—namely, "a frozen product containing not less than 8 per cent. milk-fat and not less than 10 per cent. milk solids not fat." It was proposed that all manufacturers and vendors of ice-cream should be licensed by local authorities who should inspect their premises. The view of the association is said to be that those who want to sell a frozen confection which contains no cream should be compelled to use some description not containing the word "cream."

SURGICAL INSTRUMENT MANUFACTURERS' ASSOCIATION.—The annual dinner of this Association was held at the Holborn Restaurant on Oct. 14th, under the presidency of Mr. E. W. Mayer. The guests included Sir John Corcoran, Mr. Cecil Rowntree, F.R.C.S., and Mr. L. Ferris-Scott. Mr. Patrick C. Maw, proposing the health of The Association, regretted that they had failed to secure protection for their industry, but said that efforts were being made to secure an Order under the Merchandise Marks Act for the marking of all imported surgical instruments with the country of origin. Mr. Rowntree said that British surgical instruments were the best in the world; not only were they the best, but they were works of art which could compare with the artistic products of the forge and bench in any walk of life. Mr. Ferris-Scott remarked on the enormous debt which the medical profession owed to the surgical instrument makers of this country.

CONGRESS OF HYDROLOGY AT LYONS.—The Twelfth International Congress of Hydrology, Climatology, and Medical Geology was held at Lyons from Oct. 4th–12th. Large numbers of medical men, chiefly from France, took part in the proceedings. At the closing session, over which Mr. Herriot, Minister of Public Instruction and Mayor of Lyons, presided, Dr. Fortescue Fox, representing the British Government, referred to the English reputation for insularity and affirmed that it was now impossible for any country to live for itself alone. In science, at any rate, the English were internationalists. The branch of medicine with which the Congress was concerned was in a strange position, because, although it was the most ancient part of medical treatment, although it was widespread in all countries, although generations had proved its benefits, its intimate secrets had still to be discovered. The work of discovery had been begun, nowhere better than in France, but very much remained to establish the foundations of our knowledge and to make it generally available.

ROYAL VICTORIA HOSPITAL, BELFAST.—The present session opened on Oct. 14th, when an address was delivered by Mr. P. T. Crymble. Contrasting the mental outlook of the undergraduate and the graduate in medicine, he pointed out that the former had his course mapped out for him and a clear path to pursue, whereas the latter had various possibilities before him. General practice offered the easiest alternative, with a fair prospect of an early competence and the possibility of marriage. Specialism usually involved a long waiting period, but a higher qualification than that of M.B. was often advisable. The Services offered to many an attractive prospect—an immediate good income, a pension, and good social position—but it should not be overlooked that an income satisfactory to a single man of 24 was very inadequate for a married man of 45. He advised all his hearers to specialise to some extent upon some department of practice. One practitioner might become an expert radiographer, another might concentrate upon the digestive tract, another upon clinical bacteriology, another upon obstetrics. Even if they did not definitely specialise in such subjects their standards would be raised to a higher level. Mr. Crymble's address was enlivened by many happy strokes of wit, and was much enjoyed by the large audience. A cordial vote of thanks was passed to the lecturer on the motion of Colonel Andrew Fullerton, seconded by Dr. J. S. Morrow.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—On th ground that the constantly increasing work and scope this institution require the services of a younger and mo active man, the Earl of Denbigh has resigned the chairma ship, which he has held for a quarter of a century.

MANCHESTER AND SALFORD SKIN HOSPITAL.—Th Norris Midwood Memorial Wing of this institution, which h cost £14,000, was opened last week. The extension, whic contains a new X ray department, rooms for treatment b artificial sunlight, and additional acommodation for nurse increases the number of beds to 50. The wing is a memori to the late Mr. Norris Midwood, who was long a member the board.

MEDICAL MAYORS.—Dr. George Brown Hillma who has been elected Mayor of Wakefield, was educated the Leeds School of Medicine and has practised in the We Riding for 35 years. A member of the West Riding Coun Council, he also serves on the West Riding and Wakefie Insurance Committees, the East and West Riding Voluntar Hospitals Committee, and other public bodies. As chai man of the Medical Propaganda Subcommittee of th Yorkshire Council of the British Empire Cancer campaig he has become well known throughout the country f industry and enthusiasm.—Dr. Arthur Hastings Bosto has accepted the unanimous invitation of the Chichest City Council to serve as mayor during the coming yea His father, the late Dr. A. S. Bostock, was mayor Chichester in 1885, 1886, and 1891.

MR. CHAMBERLAIN ON HOSPITAL POLICY.—M Neville Chamberlain, the Minister of Health, has issued statement upon his hospital policy, in which he once mo points out the danger to the voluntary system of la of coöperation with other types of hospital. While the are thousands of empty beds in Poor-law hospitals, eve voluntary institution has a waiting-list. "In the nar of common sense, hospital accommodation should be treat as a whole so that there should be no waste." If the Poo law institutions became municipal hospitals the stig of pauperism would be removed and it would then not difficult to form some joint body, representing both typ which should decide upon the need of extension, the directi in which it is needed, and the place where it should provided. In this way the existing accommodation wo be used to the utmost extent by the interchange both patients and staff.—The Scottish Regional Committee the British Hospitals Association is asking the Secreta for Scotland to receive a deputation with a view to ascerta ing the policy of the Government in connexion with t proposed new Poor-law legislation for Scotland so far it affects the voluntary hospital system.

Medical Diary.

Information to be included in this column should reach in proper form on Tuesday, and cannot appear if it reac us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MONDAY, Oct. 24th.—8 P.M., ODONTOLOGY. Presiden Address by Mr. W. Rushton. Paper: Mr. F. Doubleday: Chronic Fuso-spirillary Infection of Periodontal Membrane and its Treatment.
TUESDAY.—5 P.M., MEDICINE. Paper: Dr. Vincent L (Philadelphia): The Technique and Usefulness Medical Biliary Drainage in Gall Tract Dise (Illustrated with lantern slides and moving pict film.)
WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. Pap Prof. O. Charnock Bradley: What is Comparat Medicine?
THURSDAY.—8.30 P.M., UROLOGY. Presidential Addr Mr. Frank Kidd: Purpura of the Urinary Tract.
FRIDAY.—5 P.M., DISEASE IN CHILDREN. (Cases at 4.30 P Dr. J. D. Rolleston: Hemiplegia following Sca Fever. Dr. E. A. Cockayne: Renal Dwarfism. W. M. Feldman: Pointing Empyema and Tubercu Rib. Prof. Dible and Dr. Chodak Gregory: Specim of Adenomatous Hypertrophy of Kidney. Other c will be shown. 8 P.M., EPIDEMIOLOGY. Paper: E. W. Goodall: The Epidemic Constitution.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, W.
THURSDAY, Oct. 27th.—8.30 P.M., Sir W. H. Willc Recent Advances in Toxicology and Forensic Medi (Presidential Address).

MEDICAL SOCIETY OF LONDON, 11, Chandos-str Cavendish-square, W.
MONDAY, Oct. 24th.—8.30 P.M., Dr. B. B. Vincent L U.S.A., will introduce a discussion on the Develop of the Duodenal Tube and its Practical Value Diagnosis and Treatment.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY, St. John's Hospital for Diseases of the Skin, 49, Leicester-square, W.C.
WEDNESDAY, Oct. 26th.—4.15 P.M., clinical cases and discussion on Pemphigus, to be opened by Dr. J. E. M. Wigley.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Oct. 24th, to SATURDAY, Oct. 29th.—FELLOWSHIP OF MEDICINE. Special lecture at the Medical Society, 11, Chandos-street, W., Mon., 5 P.M., Mr. Herbert J. Paterson: Surgical Hints.—ROYAL NORTHERN HOSPITAL, Holloway-road, N. Special surgical demonstration by Mr. J. B. Hunter at 2 P.M. on Mon. Special medical demonstration by Dr. Bruce Williamson at 3 P.M. on Tues.—CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd-street, W.C. Special ophthalmic demonstration by Mr. Cunningham at 4 P.M. on Thurs. (The above are open to the medical profession without fee.)—ROYAL EYE HOSPITAL, St. George's Circus, S.E. Series of demonstrations on the Diagnosis and Treatment of Diseases of the Eye by members of the staff in the afternoons at 3 P.M. Mon. to Fri.—PADDINGTON GREEN CHILDREN'S HOSPITAL AND VICTORIA HOSPITAL FOR CHILDREN. Combined course in Diseases of Children, occupying all day. Sessions at each hospital alternately.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Course in Gynæcology. Operations and lectures daily.—THE NATIONAL HOSPITAL, Queen-square, W.C. Special two months' course in Neurology. Further information from the Secretary, Mayfair 2236.

WEST LONDON HOSPITAL, POST-GRADUATE COLLEGE, Hammersmith, W.
MONDAY, Oct. 24th.—11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Armour: Operations. 4.30 P.M., Mr. Addison: Appendicitis (lecture).
TUESDAY.—10 A.M., Medical Registrar: Ward Demonstration. 2 P.M., Mr. Sinclair: Surgical Out-patients. 4.30 P.M., Dr. Shaw: Emphysema.
WEDNESDAY.—10 A.M., Dr. Owen: Medical Diseases of Children. 10 A.M., Dr. Burnford: Medical Wards.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Dr. Ironside: Medical Out-patients. 3 P.M., Sir H. Simson: Gynæcological Ward.
FRIDAY.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Mr. Addison: Operations. 2 P.M., Dr. Shaw: Medical Out-patients.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy and Ward List. 10 A.M., Dr. Owen: Medical Diseases of Children.
Operations, Medical, Surgical, and Special Out-patients, daily 10 A.M. to 5 P.M.: Saturdays, 10 A.M. to 1 P.M.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham, S.W.
THURSDAY, Oct. 27th.—4 P.M., Dr. Hector C. Cameron: Pneumococcal Infections in Childhood.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Oct. 24th.—2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.
WEDNESDAY.—2.30 P.M. to 5 P.M., Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M. Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics, 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.
There will also be a special demonstration of ear, nose, and throat cases at 2 P.M. on Tues., Oct. 25th, and of surgical cases at 2 P.M. on Thurs., Oct. 27th, by Mr. W. Ibbotson and Mr. H. W. Carson respectively.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Oct. 27th.—4 P.M., Mr. Doyne: Corneal Ulceration.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Oct. 26th.—4 P.M., Sir H. Gauvain: Tuberculosis as a Problem of Childhood.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Oct. 25th.—5 P.M., Dr. H. W. Barber: Immunity and Anaphylaxis.
THURSDAY.—5 P.M., Dr. W. Griffith: Principles of Treatment. General.

PEOPLE'S LEAGUE OF HEALTH, 12, Stratford-place, W.
WEDNESDAY, Oct. 26th.—4 P.M., Prof. F. T. G. Hobday: Some Diseases Conveyed to Man from Animals and their Prevention.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Oct. 25th.—4.15 P.M., Dr. C. H. Melland: Some Medico-Legal Cases.
FRIDAY.—4.15 P.M., Dr. J. Gray Clegg: Microscopy of the Living Eye.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, Oct. 28th.—3.30 P.M., Mr. Hay: Clinical Cases.

Appointments.

GORDON, A. KNYVETT, M.B., B.Chir. Camb., has been appointed Hon. Consulting Pathologist to the Victoria Hospital, Swindon.
KISSEN, H.S., M.B., Ch.B. Edin., Outdoor Medical Officer for the Springburn District of Glasgow.
MACMILLAN, D., M.D. Edin., Junior Assistant Physician at Crichton Royal, Dumfries.
MOORE, D. L. H., M.B., B.Ch. Dub., Certifying Surgeon under the Factory and Workshop Acts for the Exmouth District of the County of Devon.

Vacancies.

For further information refer to the advertisement columns.
Bermondsey Guardians, Ladywell Poor-law Institution, Ladywell-road, Lewisham, S.E.—M.O. £400.
Bermondsey Guardians, Shirley Schools, Wickham-road, nr. Croydon.—Part-time M.O. £350.
Birmingham and Midland Eye Hospital.—Res. Surg. O. £150.
Birmingham, Witton Babies Hospital.—Res. M.O. £150.
Birmingham, Woodlands Open Air Orthopædic Hospital.—Jun. H.S. At rate of £150.
Bolingbroke Hospital, Wandsworth Common, S.W.—H.P. At rate of £120.
Brighton, Royal Alexandra Hospital for Sick Children.—H.S. At rate of £120. H.P. At rate of £100.
Bristol, Brunswick Maternity Hospital, Brunswick-square.—Asst. Phys.
Burton-on-Trent, Bretby Hall Orthopædic Hospital.—Res. M.O £450.
Cambridge, Addenbrooke's Hospital.—Hon. Asst. P. to Out-patient Dept.
Cancer Hospital, Fulham-road, S.W.—H.S. At rate of £100.
Central London Ophthalmic Hospital, Judd-street, W.C.—Asst. Surg.
Colindale Hospital, Hendon.—Jun. Asst. M.O. £500.
Croydon General Hospital.—Cas. H.S. £125.
Derby, Derbyshire Royal Infirmary.—Ophth. H.S. £150.
Dumfries, Crichton Royal Mental Hospital.—Clin. Pathologist. £400.
Edinburgh Royal Infirmary, Eye Dept.—Sen. Clin. Asst., &c. £145.
Hospital of St. John and St. Elizabeth, 40, Grove End-road, N.W. Asst. S.
Liverpool City.—Medical Visitor under Lunacy Act.
Metropolitan Ear, Nose, and Throat Hospital, Fitzroy-square, W. H.S. £150. Also Anæsthetist.
Newark Hospital and Dispensary.—Res. H.S. At rate of £150.
Ovamboland, South-West Africa.—District S. £1000.
Portsmouth, St. Mary's Infirmary, &c.—Third Asst. Res. M.O. £250.
Royal London Ophthalmic Hospital, City-road, E.C.—Pathologist and Curator. £200. Also Dental Surg.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.S. At rate of £100. Also Asst. Radiologist. £50.
St. Leonard's Hospital, Shoreditch.—Asst. M.O. £350.
Salford City.—Asst. Maternity and Child Welfare M.O. £600.
South Wales Sanatorium, Talgarth, Breconshire.—Res. M.O. £350.
Swansea Hospital.—H.S. to Ophth. and Aural Depts. £150–£200.
Swindon, Wilts, Victoria Hospital.—Res. M.O. At rate of £100.
University College Hospital, Gower-street, W.C.—Asst. Radiologist. £200.
University of London.—Associate Examiners.
Wallingford, Berks Isolation Hospital.—M.O. £15 15*s.* and £1 10*s.* per case admitted to Hospital.
Willesden, General Hospital, Harlesden-road, N.W.—P. in charge of Dept. for Dis. of Skin.
Wolverhampton and Staffordshire Hospital.—Hon. Fracture and Orthopædic S.
The Chief Inspector of Factories announces a vacant appointment for a Certifying Factory Surgeon at Snodland (Kent).

Births, Marriages, and Deaths.

BIRTHS.

DUNCANSON.—On Oct. 11th, at Braxted-park, Streatham, S.W., the wife of Dr. J. Gray Duncanson, of a daughter.
MATSON.—On Oct. 13th, at Woking, the wife (*née* Viveash) of Robert C. Matson, M.R.C.S., L.R.C.P., Captain, R.A.M.C. (retd.), of Fir Ridge, Hook Heath, Woking—a son.
SLEIGH.—On Oct. 11th, the wife of Dr. J. C. Sleigh, Albany Cottage, Dedham, of a daughter.

DEATHS.

BRIDGES.—On Oct. 6th, at 2, Courtfield-road, S.W., Helen Constance (*née* Scott), the devoted wife of E. Chittenden Bridges, M.D.
DOWN.—On Oct. 14th, at 9, The Crescent, Plymouth, Edith Monica Down, M.B., B.S., eldest daughter of Dr. and Mrs. Elgar Down.
MACPHERSON.—On Oct. 15th, at Evelyn-gardens, S.W., Major-General Sir William Grant Macpherson, K.C.M.G., C.B., LL.D., aged 69.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE PHYSIOLOGICAL BASIS OF THE MINIMUM WAGE.*

BY V. H. MOTTRAM, M.A. CAMB.,
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF LONDON, AND HEAD OF THE PHYSIOLOGY LABORATORY, KING'S COLLEGE FOR WOMEN (HOUSEHOLD AND SOCIAL SCIENCE DEPARTMENT).

AT first sight the task of calculating the cost of living at a subsistence level appears simple. The amount disbursed for food in the working-class household varies from about 50 per cent. of the total income to 66 per cent., or even higher. As the income decreases the proportion which goes on food rises, till it reaches its highest level among the very poorest.[1] If the physiologist can calculate the minimum cost of a theoretically sufficient diet—one which yields sufficient calories, protein (both first-class and otherwise), fat, carbohydrates, salts, roughage, and vitamins A, B, C, D, and E—he has given a figure for by far the largest portion of the cost of subsistence. With the help of the economists, it should not be difficult to calculate the cost of the remaining moiety of expenses. The sum of the two would give the cost of subsistence—a cost upon which the minimum wage surely must be based.

Minimum Cost of Subsistence.

It is quite easy to calculate the minimum cost of a theoretically sufficient diet, and I imagine that economists, in collaboration with physiologists and medical men, would have little trouble in calculating the minimal cost of adequate heating, lighting, shelter, and clothing. The sum is the minimal cost of subsistence. But this is exactly where the trouble begins. Apart from the fact that it is debatable whether a minimum wage should ever be allowed to sink so low as the minimal cost of subsistence, and whether the individual or the family should count as the unit, it is clear that, while the armchair physiologist and economist may be able to calculate a theoretical minimum subsistence cost, it is the community which will have to decide whether their conclusions are just and practicable. Psychology invades the problem, for man is no Robot, whom you can stoke with the same monotonous fare day after day. He demands some modicum of variety.

Here, for example, is an attempt to calculate a subsistence level diet.[2] It contains 7¼ oz. of fresh herrings, 1 lb. 7 oz. of oatmeal, and 4 oz. cabbage per day. This diet is obtained by taking the cheapest source of animal protein (fresh herrings) and providing enough to give 30 g. per day. Then the remainder of the day's calorie needs is supplied by the cheapest source of calories (oatmeal), and 4 oz. of cabbage added to supply vitamin C. Theoretically this diet would yield over 3000 great calories, 100 g. of protein—30 per cent. of this being first-class protein—reasonable proportions of fat and carbohydrate (74 : 459), and vitamins A, B, C, D, and E. The cost of this diet is about 6*d.* per day, or, accurately, 3*s.* 4½*d.* per week. This is the lowest conceivable diet upon which subsistence with efficiency is possible.

But, of course, such a subsistence diet is impossible. No one could swallow 1½ lb. of oatmeal a day, nor tolerate the monotony of the diet, even supposing he had the physiological knowledge to purchase such a diet and the practical knowledge of how to cook and serve it so that it were not revolting. One thing which has become abundantly clear in physiological research is that appetite,[3] as apart from hunger, has much to do with the proper digestion, assimilation, and utilisation of food. The physiological engines of the body are guided partly by the psychological condition of their owner. Consequently no subsistence diet, however admirable from the theoretical point of view, such as the one given, can be accepted as practical.

Calculation from pre-War Data.

The next method of approximating to the cost of a practical minimum food expenditure is to take diets which in the past have been considered to be sufficient, based on investigation into the way in which the working classes live. It is obvious that you must respect their traditions, and, if necessary, develop or modify them by education as much as is possible. It is no use trying to impose a diet foreign to their traditions from without.

This has been done in the past by many investigators and more notably by Rowntree,[4] who has published data of suggested minimal diets for the working class. These data have been accepted, if not for practice, at any rate as a basis of discussion. The latest figures he gives are for 1914, and the cost of his dietary works out at about those of convicts and inmates of workhouses at the prevailing rates at the time when the estimates were made. We might take these figures and multiply them by an index to represent the rise in the cost of food and take the result (approximately 7*s.* 6*d.* per week) to represent the cost of a subsistence diet for an adult male—not, of course, a theoretical subsistence diet, but a diet upon which it is not wise to economise.

Unfortunately much has happened in the world of dietetics since 1914. Consequently it has seemed better to recalculate from the beginning so that the newer knowledge of the vitamins, the importance of first-class protein and of mineral matter and roughage, and the value of the imponderables in dietetics, such as flavour, service, and personal likes and dislikes as regards food, should be given due weight.

Calculation from Modern Data.

Let us make the assumption that an adult male needs from 3000 to 3500 great calories per day, which are to be obtained from the combustion of about 100 g. of protein (30 per cent. of which must be first-class protein), 50 to 100 g. of fat, and of 400 to 500 g. of carbohydrate. Further let us assume that this dietary must contain vitamins A, B, C, D, and E, some roughage and mineral matter—e.g., iron, phosphorus, calcium, chlorine, and iodine. Most investigators would agree that such a diet is adequate though no satisfactory estimates exist of the necessary amounts of vitamin-containing foods. In addition, the diet must be varied and palatable, and not depart markedly from what is acceptable to a working-class community.

Below is an attempt to construct a cheap and satisfactory dietary which will satisfy the criterions we have adopted above. It was obtained in the following way. The late Sir William Bayliss's[5] aphorism, "Take care of the calories and the proteins will take care of themselves," is roughly true and served as the starting-point. It was assumed that it would be possible to discover an adequate diet costing on the average about 3*d.* per 1000 calories. (Agricultural labourers in Essex manage on 3·3*d.* per 1000.) Foods were ranged in the order of their cost per 1000 calories and the main bulk of the diet chosen from those foods the cost of which was 6*d.* per 1000 or under. These included haricot beans, white flour, wholemeal, oatmeal, white and brown breads, vegetable and animal margarine, macaroni and spaghetti, dried peas, sago, sugar, dates, tapioca, currants, figs, potatoes, suet, treacle, neck of (imported) mutton. From inspection of this list it was clear that while it would be easy to obtain the calories, it would not be easy to get variety, first-class protein and the vitamins, particularly A, C, and D. Consequently, therefore, there was added to it fresh herrings (for first-class protein and vitamins A and D), cheese (first-class proteins, vitamins A and (?) D), cabbage, tomato, lemon, lettuce or watercress (to supply vitamin C, mineral salts and roughage), beef and bacon (to give variety) and milk. Cocoa and tea were adopted as beverages.

From such a list of foods my colleague, Miss Jessie Lindsay, who is in charge of the Household Work Department of this College, aided by Miss Tress, worked out a series of menus for a week which, when analysed, gave 12 oz. meat, 2¾ pints of milk, 8¾ oz. sugar, 14¾ oz. treacle, 8¾ lb. of bread and flour, 4 oz. cheese, 8 oz. margarine, 3½ lb. of potatoes, 1 lb. 5 oz. fresh fruit and vegetables, 13½ oz. suet and dripping, 14¼ oz. oatmeal, macaroni, &c., 1 oz. cocoa, ¼ lb. tea, 1 lb. herrings, 1½ lb. of dried fruit, and 9 oz. pulses.

These figures closely approximate to the distribution of foodstuffs found in actual use by A. B. Hill, by Rowntree, and by the 1918 Agricultural Wages Board Inquiry.[6] The meat is slightly reduced below Hill's and Rowntree's estimates, and considerably below the Wages Board Inquiry, while the milk is increased and the fish, fats, cereal products, and dried fruits largely increased. This has been done to obtain the benefit of the protein and calorigenic value of milk,[7] the protein and vitamin A and D values of herrings, and the high calorigenic values of the cereals and the dried fruits.

When this dietary is analysed for proteins, fats, carbohydrates and calories the yield is, per day, approximately 94 g. of protein (of which 29 g. is first-class protein), 115 g. of fat, 545 g. of carbohydrate, and 3350 great calories. Vitamins A and D are represented in the meat, the herrings, the suet, the milk, and probably in the dripping; vitamin B in the oatmeal, bread and vegetables; and vitamin C in the tomato, lemon, and potatoes.

Such a diet as regards proteins is about adequate, while in fat, carbohydrate, and calories it is adequate. As regards vitamin C, perhaps it is adequate (one tomato, one lemon, and ½ lb. cabbage per week). Its cost, at the lowest prices prevailing at the moment, is 6*s.* 3*d.* [These figures are for London, October, 1927.]

A Reasonable Dietary.

Of course, the dietary would not suit all tastes. It is a north country rather than a south country diet, but

* Introducing a discussion at the Conference on Family Endowment, Oct. 15th, 1927.

the types of food used—e.g., oatmeal—and in the amount of cooking required. It would not be easy to cook it on a gas-ring shared by one or two other families. Further, some of the dishes to be prepared—e.g., macaroni cheese—are not popular in the working-class quarter in which inquiries have been made, and some foods, such as dried fruits, though popular, are not consumed in the quantities suggested. Unfortunately, almost any alteration to meet such prejudices would at once raise the cost, excepting a diminution of the dried fruits and the substitution for them of other foods. Oatmeal and macaroni are among the cheapest sources of calories, so that substituting them by anything but bread and margarine would raise the price and decrease the variety; while cutting down the dried fruit would have the disadvantage of loss of flavour from a dietary which tends to monotony. Other cheap cuts of meat—e.g., neck of mutton, flank of beef—could be substituted for the cut used (shoulder steak) with no loss in economy.

Apart from these criticisms, which more reasonable housing and education might remove, the dietary is a reasonable one; it has variety; it provides the requisites and departs but little from foods actually in use among the labouring classes. Its price tallies with that of the most economical and at the same time efficient diet which we have met: one among the 98 family budgets investigated by A. B. Hill.[6] (The actual figures of these budgets are not given in the communication referred to, but may be obtained through the courtesy of the editor of the *Journal of Hygiene*.) Among these 98 families there are eight whose expenditure on food is successful in obtaining an adequate diet. The prices paid for food per "man value" had a large range—i.e., from 6*s*. 3*d*. to 12*s*. 1*d*. It will be noted that one family was able—even though its man value was 4·86—to obtain a diet at the same figure as the one we suggest. The next above works out at 7*s*. per man value.

We may assume, therefore, that with skilful purchasing at the cheapest market, based either on a long experience or on a knowledge of dietetics, a dietary can be obtained at as low a cost as 6*s*. 3*d*. per week per adult male, so long as the occupation followed is not a very strenuous one. Below such an expenditure it is unlikely that bodily efficiency could be purchased. This sum, therefore, sets the limit from which we may proceed to estimate what minimal subsistence will cost. It must be realised, however: (1) that this figure was arrived at when food prices were low, and that any attempt to put it into practice must allow for fluctuations in the prices of foods; and (2) that it demands skill in laying out of money which only one or two housewives in a hundred appear to have. Although this figure is used throughout the rest of the discussion, my own prejudice is in favour of raising it to 7*s*. per week.

Relation of Food to Total Expenditure.

The next step is to assess what relation the money spent on food should bear to the total income. It is tempting for the physiologist to say that we ought to be able to discover the cost, at present conditions of housing, &c., in any district, of the minimum of light, air, warmth, and clothing which hygiene demands, and thus give an estimate of the cost of subsistence based entirely on physiological principles. By adding the cost of the minimal requirements of light, air, heating, and clothing to the cost of the minimal requirements of food we get the cost of subsistence with efficiency. For the present, however, it may be doubted whether this is possible, partly because one has a shrewd suspicion that the housing accommodation to meet the demands of hygiene simply does not exist.

The utmost that can be done is to multiply the cost of the minimal dietary by a definite factor, based on the average relation of the money spent as food to the total income. In actual investigations the figure runs from about 50 per cent. to 75 per cent. As was said in the opening sentences, the lower percentage is found among those whose wage is relatively good, while the higher percentage is found among the poorest. A. B. Hill's figures for the whole of the families investigated average at 68·8 per cent. We might take, as has been done in the past, a factor such as 66·7 per cent. This is sufficiently close to Hill's actual findings as well as to the findings of many other investigators in the list. This would bring the minimum subsistence figure to 6*s*. 3*d*. $\times \frac{3}{2}$ or to 9*s*. 4½*d*.

The obvious criticism of this method is that though by careful scientific discussion of a dietary, expenditure on it can be cut down without detriment to health, the amount to be spent on rent, clothing, light, and heat is not capable of such reduction. No amount of consideration will cut down the price of oil and coals. Consequently to multiply the cost of a minimal efficient diet by 150 per cent. and say that that figure should indicate the cost of subsistence is manifestly unfair. We are left with the unsatisfactory method of making a guess, though it be a guess based on definite facts. My guess is that it will be fair to assume that the food budget, reduced as it is by scientific considerations to its lowest limit, should represent 60 per cent. of the expenditure for subsistence. This gives an estimate of 10*s*. 5*d*. as the lower limit of the cost of living for the adult male. If the higher figure of 7*s*. a week for food be adopted, the basic minimum becomes 11*s*. 8*d*.

This figure is provisional only. It is based on assumptions which may turn out to be untrue. It must be increased if longer hours per day are worked, or more arduous work undertaken. It must vary with the varying levels of prices. It will alter from place to place and time to time, and it will be affected by what the public conscience demands in the way of housing, lighting, heating, sanitation, &c.

The figure, 10*s*. 5*d*. (or, if we take the more cautious estimate, 11*s*. 8*d*.), is the basic figure for the adult male. The problem arises: what of the wife and children of the adult male? As long as the unit in the country is supposed to be the family and not the individual, so long must the basic minimum be raised from its adult male value to the value equivalent to a family expressed as adult males. Thus a family of father, mother, and one child under 6 counts as 1+0·83+0·5 adult males=2·33.

A Statistical Fiction.

There is a fiction of a "standard family" which consists of father, mother, and three children, and is supposed to be approximately equivalent to four adult males. For such a family the income per week should not fall below 4 × 10*s*. 5*d*., or 41*s*. 8*d*.

The "standard family" is not even a convenient abstraction, for in no way does it correspond to reality. In the Essex budgets[6] the man value of the family (on a rather low standard of estimation[8]) was on the average of 98 families as high as 4·9, instead of the "standard family" of 4. Of the 63 families receiving less than the average income per "man," six only had "standard families"; the rest had larger families. No family obtained a diet which the physiologist would pass as adequate. Of 35 families receiving more than the average wage per man, 27 were below the physiological minimum, while only eight exceeded it. Six of these successful families counted for much less than the "standard family"—1·83 to 3·23—and one of the two families of more than standard size was living rent free. It is fairly clear from consideration of even these figures only that the standard family is a myth, and that a large family usually coincides with poor living. (Incidentally the almost complete inability of this group of families to obtain satisfactory food on an income per man value averaging 8*s*. 0¾*d*. is evidence that the figure we have chosen—viz., 10*s*. 5*d*.—is no wild Utopian figure.)

Summary.

Any attempt to calculate from physiological principles the minimum wage which should be paid on the assumption that the family is the unit, must take into account the size of the family. The needs of the family—more particularly their food needs—vary with the size of the family. Whether it is feasible to adjust a minimum wage so that it is adapted to the size of each individual family, and if feasible, whether right and proper, are questions into which economists and politicians must probe and the electorate settle. The following statements summarise the position so far as it concerns the physiologist:—

1. A basic minimum diet for an adult male costs at the present time, and in the cheapest London markets, at least 6*s*. 3*d*. per week.

2. If we assume that 60 per cent. of the income of a person at subsistence level should go on food, the minimal expenditure per week per adult male should not go below 10*s*. 5*d*. The actual figure must vary with market fluctuations of price.

3. Should we proceed to calculate a minimum wage on the assumption that each male wage-earner is the head of a standard family equal to four adults, we should fix such wage at 41*s*. 8*d*. per week. As, however, the standard family is a myth, and the assumption of its existence would push many families below the poverty line, any calculation of a minimum wage based on physiological principles must take into account the man value of each individual family.

FOOD POISONING.

THE MALCOLM MORRIS MEMORIAL LECTURE.

THE lecture was delivered this year, by arrangement with the Chadwick trustees, at the B.M.A. House, Tavistock-square, on Oct. 17th, when Dr. W. G. SAVAGE (M.O.H. for Somerset) dealt with the subject of Food Poisoning. Sir WILLIAM COLLINS presided.

Food poisoning, Dr. Savage said, had been a question of considerable interest from the earliest days, though of late years, owing to the greater variety of foods, it had assumed a different form. The necessity for conserving food for long periods and the desire of the public to have its palate tickled with food made in different ways had helped to keep up the amount of food poisoning, despite the efforts continually being made to improve public health. The simplest type of food poisoning was that caused by a definitely poisoned animal or plant having been consumed. In this country there was not much illness caused by eating poisoned animals, but mushroom and other forms of poisoning were fairly common. A fairly simple kind was that by chemical substances which had been accidentally introduced into food, such as apples which had been sprayed with an arsenical compound. In 1922 200 people suffered from poisoning which was traced to apples having been cooked for some hours in a zinc container, the acid having dissolved sufficient of the zinc to produce the poison. Recently four members of a family partook of breast of mutton and afterwards suffered from belladonna poisoning. It was found that mixed with the sage for the stuffing were some belladonna leaves. Outbreaks of chemical poisoning, however, constituted but a very small part of the whole. Most were due to bacteria. Seventeen persons who partook of some brawn were ill, and three died, and it was discovered that the pig in question had suffered so badly from a diseased leg that it could not be walked to market. Three of the patients had eaten only the vegetables which were cooked in the same vessel.

Ptomaine Poisoning a Misnomer.

Dr. Savage said a good deal of misconception prevailed concerning ptomaine poisoning. It arose from the idea that the cause of the illness was the fact that the food was tainted or decomposed. Ptomaine poisoning was really a misnomer. Certain chemists, working on the subject, allowed food to putrefy to an objectionable degree, and were able to extract from it chemical substances, to which they gave the general name ptomaines. When these were injected (as opposed to fed) into animals violent symptoms ensued, and this was held to prove that decomposed food caused, when ingested, the poisoning known as ptomaine poisoning. Ptomaines, however, it was now clear, had nothing to do with the problem at all. In most cases of food poisoning the food itself was perfectly good physically, but poisonous bacilli had gained access to it without causing any naked-eye changes, nor alterations in the smell or taste. Many food-poisoning outbreaks were conveyed by such food as fruits which did not decompose. Usually the contamination of foods could be traced to the handling they received in dirty and unwholesome surroundings before the consumer received them. At least three-fourths of the outbreaks of food poisoning in this country were due to bacilli of the Salmonella group. Concerning this group, three points were important: (1) they multiplied with great rapidity in food, particularly during hot weather; (2) during their growth on food they did not produce in it physical changes which were discernible to the unaided eye; (3) they produced toxins in the process of growth which were very irritant. In rabbits extreme irritation of the stomach wall was evident within six hours of eating the food so contaminated. These food cases occurred at all times of the year, but, naturally, most in the hottest months, the upward curve usually commencing in April.

The Kinds of Food-Vehicle.

With regard to the kinds of food which acted as the vehicles for the Salmonella bacteria, he had been through the details of 200 outbreaks, and worked out the percentages. Thirty per cent. were due to the eating of canned foods; 7 per cent. milk, 8 per cent. milk products (mostly ice-cream and cheese), 27 per cent. made-up meats, 4 per cent. manipulated food like stuffed meat, 16 per cent. in fresh meat, 4 per cent. fruit or vegetables, 3 per cent. other foods not here mentioned. In no less than 72 per cent. the poisoning was traced to foods which had been man-handled in some way—canned foods, sausages, brawn, "faggots," chopped meat. Many of the incriminated foods were those which, having been mixed, were heated and allowed gradually to cool, brawn and ice-cream forming a large class in these. It was most probable that the contamination took place during the cooling if the surroundings were dirty and dusty. While the material was hot, any bacilli alighting on it would probably be killed off, but at subsequent stages in the cooling the temperature would be congenial, and rapid multiplication would occur. An outbreak in 1923, in which many hundreds of people we ill—though only one died—was traced to ice-cream havi cooled in a filthy place, and been sold through the stree from three hand barrows. Salmonella bacilli were isolate A very important feature about Salmonella bacilli was tha alone among microbes, their toxin was heat-resisting. T toxin could be boiled for an hour or more and yet its leth character was not disturbed.

The cases of poisoning due to the eating of canned me were of exactly similar character; their incubation peri was short—i.e., two to four hours—and the symptor were acute vomiting, diarrhœa, and acute abdominal pai The acuteness, however, seldom lasted more than 24 hou and the deaths from it were very few. When a fatal resu ensued the person was usually already the subject of sor disease such as diabetes. The mere distension of a t containing food was not a sure indication of the presen in it of poisonous gases.

Attacks of botulism were quite infrequent in this countr but not so rare in the United States. Still, at Loch Mar (Ross-shire) a bad outbreak of botulism occurred in 192 Eight people started on a fishing expedition equipped wi sandwiches containing wild duck paste preserved in gla jars. Some time after eating them the members of t party suffered from symptoms in nerves, eye, and thro and examination of scraps remaining in a glass jar reveal the *B. botulinus*. The disease was well known in Germar and in Russia was said to be on the increase, due th principally to fish. In the United States it was chie traced to preserved fish and olives, and the profession th energetically set to work to trace the disease to its sour and stamp it out.

The Question of Prevention.

With regard to the important subject of prevention, was now clear that the Salmonella bacilli were not norn denizens of the human intestine, but they had been fou in diseased animals, therefore outbreaks might start fr the eating of the flesh of diseased animals. In Germa where the system of meat-inspection was closer than ou it had been definitely proved that botulism could ar from drinking the milk of a diseased cow. It was not lik to be spread by human carriers. *B. botulinus* occur in the soil. The main preventive, of course, was care attention to sterilisation and the prevention of dust inf tion. It was essential to try to hunt out the reserv of the offending bacilli and destroy them, as in the case the anopheles in malaria; and the heat needed to dest any bacilli without prejudicing the nutritive value of food must be ascertained. Scrupulous cleanliness co not be too much insisted on. Section 12 of the Regulati applying to slaughter-houses was of much importan seeing that it prohibited the carrying on of any process those places, such, for instance, as the making of tri sausages, and pickling meat. Rats and mice must exterminated from the surroundings of food preparati He did not think the legislature exercised sufficient con over the preparation and manufacture of made-up foo there was, he contended, urgent need for the registrat of premises where such processes were carried out, w periodic inspection, carrying with it the power to close s as were not satisfactory. In a general way he would it was unwise to eat made-up food of which one kn nothing, especially bearing in mind that in most cases c taminated food did not carry on its face any evidence of fact. Unfortunately there was still a good deal of misc ception on the subject. Dr. Savage hoped that one resul this popular lecture would be an increased willingness on part of the lay public to help medical officers and others in good work for the community in which they were engage

TREATMENT OF PSORIASIS WITH THYMUS.

ANY success claimed in the treatment of psoriasis deser careful investigation. In the *Medical Journal and Re* of August 17th Dr. F. F. Ward, of New York, recomme hypodermic injections of thymus, a suggestion doubt springing originally from the work of Brock, of Hambu who has reported on the effect of irradiating the thy for this disease. The claims which Brock has put forw have not been confirmed by the experience of other work those now advanced by Dr. Ward can easily be put to test, for preparations of thymus gland for subcutaneou intramuscular injection are on the English market. Ward used a preparation made by Harrower, and inje 1 c.cm. into the buttock three times weekly. Benefit observed in a month, and cure was complete in his case in six months. In only one case did the treatm fail, and it is affirmed that no local or general reactions be feared, but the number of cases is not stated, and question of relapse is not discussed. Every dermatolo knows that injection of a staphylococcus vaccine, a mi *Bacillus coli* vaccine, boiled milk, and many other for proteins will temporarily cause involution of psoriasis les in some cases, though these effects are extremely uncerta

ON

CHRONIC GASTRITIS:

ITS RELATION TO ACHYLIA AND ULCER.

elivered at the London Hospital Medical College on May 20th, 1927,

BY KNUD FABER, M.D., LL.D.,

OFESSOR OF CLINICAL MEDICINE AT THE UNIVERSITY OF COPENHAGEN.

FEW conceptions of disease have suffered such issitudes as that of gastritis. Broussais brought it the front 100 years ago as the alleged cause of arly every pathological phenomenon, and Andral d Louis considered it extremely common. The neral error was, however, to take the autopsy dings of congestion, discoloration, and softening as ns of inflammation. That these changes really re the simple results of digestion and putrefaction d been already demonstrated in 1838 by Carswell, University College, London. Yet the authority of kitansky was so great that a macroscopic diagnosis s thought quite enough, and "catarrhal inflamma- n" of the stomach—*Magenkatarrh*—was a favourite gnosis with clinicians in the middle of last century. early as 1829, Barras, in Paris, had differentiated vous gastralgia and dyspepsia from gastritis; and conception of purely functional disturbance in st patients gained more and more adherents in nce. Confusion and uncertainty reigned every- ere. While microscopy formed a basis for the dy of the lesions of other organs, such as the neys and liver, it failed with the stomach, because rapidly developing post-mortem changes precluded ninute microscopic examination of the mucosa. this reason the excellent work of Handfield es and Wilson Fox, in the middle of the century, disregarded.

When physiological examination of the stomach by ans of the stomach-tube and test-meals was oduced—on the initiative of Kussmaul and be—much important information was gained but little understood. The two outstanding disturb- es of secretion, hyperchlorhydria and anacidity, e demonstrated and erroneously elevated to the us of diseases; they ought really to have been arded in the same way as the subjective symptoms, cause of which had to be investigated in each vidual case]. When no secretory disturbance found, the diagnosis of nervous dyspepsia was le; and this term was gradually extended to ude the hyperchlorhydria and the anacidity, re no definite ulcer or cancer could be made out. eed, hyperchlorhydria was considered more a se than an effect of ulcer. Gastritis and catarrh he stomach were less and less discussed and nosed, because mucus was rarely demonstrated he stomach contents, and mucus was considered criterion of catarrhal inflammation.

pinion changed when it became possible to erve the stomach by injecting fixation fluids ediately after death. In France Hayem (circ. 8)) injected a solution of potassium bichromate the stomach, and described in detail the minute omical changes. To him gastritis was a very uent and predominant lesion in gastric pathology; he was not able, even in France, to dispel the blished opinion that functional disturbances e the most frequent. In 1900 Faber and Bloch oduced the method of injecting 10 per cent. alin into the abdomen immediately after death; is way they obtained an excellent fixation of the ach mucosa. It was soon clear that inflammatory ges were frequent and important, and at the hern Congress for Internal Medicine (1904) deavoured to restore chronic gastritis to its former eminence, especially as the cause of achylia. Lately we have gained additional information on this subject by examining specimens from resections of the stomach. Konjetzny, and his pupils in particular, have enlarged our knowledge and established the importance of pyloric gastritis.

For these reasons I consider the present time suitable to outline the main points of our present position.

It is well to emphasise at once that by the term "gastritis" we now mean something different from the "catarrhal inflammation" of earlier times. Certainly the stomach has a superficial mucus-secreting epithelial layer; but, apart from this, its mucous membrane consists of a compact layer of glands with specific secretion. Hence an inflammation of the gastric mucosa would be better compared with an inflammation of some other large glandular organ—e.g., the kidney or liver. Samuel Fenwick has already drawn such a parallel between gastritis, nephritis, and hepatitis. Anatomically, however, the stomach differs from these organs in that its glandular layer is extended over a large surface and consequently may be injured in two ways: (1) via the blood (toxic and hæmatogenous agents), as can the kidneys and liver; and (2) directly, by the effect of injurious agents on the mucous membrane. The pathological phenomena caused by the gastritis are likewise of two kinds. They are partly symptoms of insufficiency—i.e., impairment of the secretory faculty from diffuse lesions of the glandular parenchyma, and partly surface lesions, erosions, and ulcerations. This applies particularly to that form of gastritis so frequently localised in the pyloric region.

The matter may conveniently be discussed in two sections, corresponding to these two main forms of gastritis.

I. PATHOGENESIS OF ACHYLIA.

The stomach-tube showed that complete anacidity is quite frequent; it was at first thought to be due to a complete atrophy of the stomach mucosa and its glands, an anadenia to which great importance was attached.

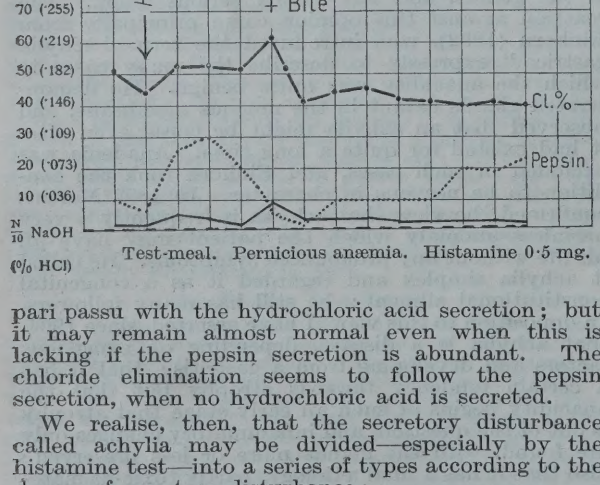
Samuel Fenwick, in 1870, was the first to demonstrate the connexion between pernicious anæmia and disease of the stomach. He laid stress on glandular atrophy as the chief characteristic; the view became general that complete anacidity was due to atrophy of the glands, and was a very serious lesion. The reaction against this opinion came principally from Einhorn (1892), who introduced the term "achylia gastrica" expressly to describe the many cases in which the anacidity was quite benign. He demonstrated glands extant in the mucous membrane, and observed that an achylia might be cured even after it had existed for quite a long time. Anadenia was excluded in such cases, and Einhorn took the condition to be nervous in character. In 1897 Martius confirmed the view that achylia is frequently a very harmless anomaly which the patient may have all his life without any pronounced symptoms. He called it achylia simplex and regarded it as a congenital constitutional ailment; he still has many followers. In opposition to this view, I have asserted, since 1904, that achylia is a disease, depending on exogenous factors and developing from a gastritis; that it has a certain tendency towards atrophy but that the anacidity begins at such an early stage that atrophy is out of the question, and inflammatory changes only are found, with the glands more or less preserved; also that it has a dual ætiology, partly toxic-hæmatogenous and partly direct injury.

Two principal considerations led Einhorn and Martius to formulate the clinical picture of nervous achylia gastrica, or the constitutional achylia simplex. One was their belief that they had found a complete cessation of gastric secretion, acid as well as peptic. The other was their discovery of this complete cessation even when the glands were anatomically preserved.

Further investigation, however, has shown that the first of these arguments does not hold good. On the contrary, even in protracted and total anacidity the secretion of pepsin hardly ever ceases altogether. The absence of pepsin, so often recorded, is due to filtration of the stomach contents before examination. The pepsin is adsorbed to the food particles and, if it is present in slight amount only, it is kept back by the filter together with the food remnants. Furthermore, an admixture of duodenal contents with the gastric juice will destroy the peptic action. In our clinic (A. Norgaard) exact analyses have always proved the presence of pepsin, although in very varying quantity, from normal to a mere trace. If under "achylia" we include cases showing no free acid and a low total acidity after Ewald's test, they can be grouped according to the degree of secretory disturbance. This has been particularly obvious since the introduction of fractional analysis, which shows that many cases have faint and delayed acid secretion, although by Ewald's test-meal they would be diagnosed as achylia. The frequency of this finding depends largely on the test-meal given. With oatmeal gruel, as at Guy's Hospital, or alcohol, as in Germany, the delayed faint secretion is seen less often than with crushed cracker. In the injection of histamine we have a new diagnostic method, which gives rise to as marked a secretion as the cracker test-meal and a more intense one than the other two meals. "False achylia," therefore, is more frequently found by this method than by using oatmeal gruel or alcohol.

The various forms of achylia are further differentiated by estimating the pepsin secretion. In some cases it remains almost unchanged, in spite of a total anacidity; in other cases it is lowered considerably; but, as mentioned, it is hardly ever completely interrupted, even in an old achylia with pernicious anæmia (Figs. 1 and 2). The total chloride elimination, after histamine injections or the alcohol test, varies similarly. Normally the amount increases

FIG. 1.



Test-meal. Pernicious anæmia. Histamine 0·5 mg.

pari passu with the hydrochloric acid secretion; but it may remain almost normal even when this is lacking if the pepsin secretion is abundant. The chloride elimination seems to follow the pepsin secretion, when no hydrochloric acid is secreted.

We realise, then, that the secretory disturbance called achylia may be divided—especially by the histamine test—into a series of types according to the degree of secretory disturbance:—

1. False achylia in which—on fractional analysis—we find a scant and tardy secretion of hydrochloric acid.

2. True total anacidity, but with preserved pepsin secretion and chloride elimination.

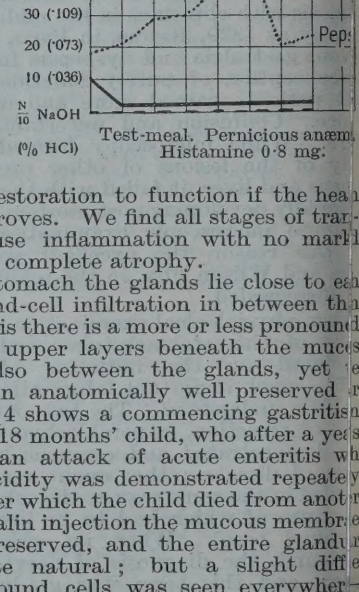
3. True anacidity with more or less impairment of the pepsin and chloride production. (Constant complete cessation of all secretion was never observed by us when the test for pepsin was carried out on the unfiltered fluid.)

Such differences in degree of functional disturbanc do not fit in well with the conception of a total achyli from defective innervation, or from a constitution congenital deficiency of secretion They correspon much better with the picture of an organic lesion different stages. In those cases of temporary nervou cessation of secretion which are sometimes shown b Ewald's test, it seems to be the rule that a histamir injection and subsequent fractional withdrawal giv normal curves of acid secretion.

Anatomical Investigation.

Similar results are shown by anatomical examin tion of the stomachs of patients with achylia. By t fixation method mentioned we have been able to stu these anatomical changes in well-fixed specimens. We find that a complete atrophy of the mucous membrane occurs exceptionally in the most advanced cases as an end-result of the gastritis. Usually its anatomical development proceeds slowly; and there may be a complete anacidity for a long time, though the glands of the mucous membrane are still intact and apparently capable of restoration to function if the hea of the mucosa improves. We find all stages of trar tion, from a diffuse inflammation with no mark glandular lesion to complete atrophy.

FIG. 2.



Test-meal. Pernicious anæm. Histamine 0·8 mg.

In the normal stomach the glands lie close to ea other with no round-cell infiltration in between th (Fig. 3). In gastritis there is a more or less pronoun infiltration of the upper layers beneath the muc epithelium and also between the glands, yet glands may remain anatomically well preserved a long time. Fig. 4 shows a commencing gastritis the stomach of an 18 months' child, who after a ye good health had an attack of acute enteritis wh achylia. The anacidity was demonstrated repeate for six months, after which the child died from anot cause. After formalin injection the mucous membr was found well preserved, and the entire glandu layer looked quite natural; but a slight diff infiltration with round cells was seen everywher a mild pangastritis. Fig. 5 shows a rather fr gastritis with achylia in a young girl who d symptoms for about six months. The glands here well preserved.

As the inflammation progresses, the glands be to show signs of injury (Figs. 6 and 7). They bec less numerous and appear separated from each ot by inflammatory products; they then atrophy u they become mere vestiges, finally disappea altogether (Fig. 8). The mucous membrane t consists of granulation tissue covered by the gas surface epithelium, a complete "anadenia." So times other changes are seen. The follicle-like ma of round cells may develop into typical lymp follicles, resulting in a "follicular gastritis." other cases cysts form in the degenerating glan occasionally this may be the predominant feat Not uncommonly the surface epithelium of stomach is converted into intestinal epitheli characterised in particular by goblet cells with mu such as are never found in the normal stom Occasionally there may even be typical glands Lieberkühn with Paneth cells.

Thus there is gradual transition from the slig injured stomach to the stomach showing ma

natomical changes with destruction of the entire ecretory apparatus. The stage of complete atrophy reached only when the gastritis has persisted for a long time, as in elderly or middle-aged individuals who have probably suffered from achylia for a good many years.

That the glands themselves may at times be anatomically intact, although their secretion has ceased, is illustrated in Fig. 9. The patient had had symptoms of cancer for six months, and had a complete achylia. In a piece of mucous membrane, removed at operation, the glands were so well preserved that it was possible to demonstrate secretory channels, Altmann's granules, &c.

Ætiology of Achylia.

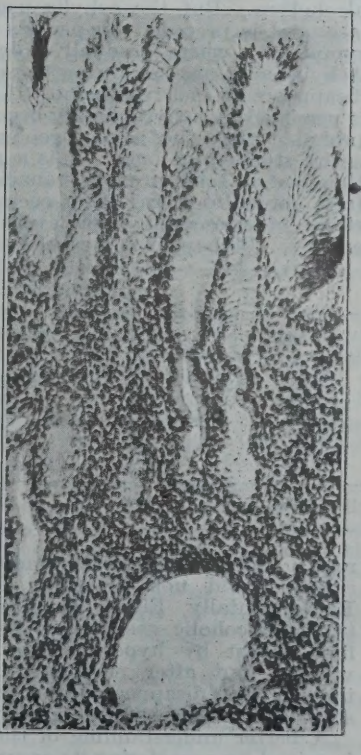
Gastritis nowadays has been generally accepted as the cause of a certain number of cases of achylia; but many authorities still hold that the so-called "constitutional achylia" is fairly common. Two arguments are always cited in favour of this view: (1) An achylia of no definite ætiological importance is frequently met with in patients of all ages who give no history of alcohol or other strongly irritating food. (2) Achylia may exist for a long time without any stomach symptoms.

The dual ætiology of gastritis must be remembered in considering the former of these. Direct irritation was formerly considered the sole cause of gastritis, and the hæmatogenous factor was overlooked. The hæmatogenous factor can best be demonstrated in children, in whom anacidity is quite common. Some exogenous cause is nearly always evident — e.g., parenteral febrile

FIG. 6.

Gastritis with achylia in a man 40 years old.

FIG. 7.



Chronic alcoholic gastritis with achylia in a man aged 51. Commencing atrophy of the glands, and some cysts.

diseases and intestinal lesions, especially infectious enteritis. In Copenhagen, especially at Bloch's pediatric clinic, it was found that an achylia very frequently developed during and after acute infectious diseases such as influenza, tonsillitis, pneumonia, bronchitis, and especially after infectious enteritis. In several cases a normal secretion had been demonstrated before the disease, and a lowered secretion for a long time after the disease. Out of 64 infants with intestinal lesions Bloch found a lowered secretion in about half (33); in 15 a complete anacidity persisted for weeks or up to 11 months. At autopsy on children dead from diphtheria and measles Jerusalem found anatomical signs of acute gastritis; and by intravenous injection of diphtheria toxin Einar Thomsen, in Copenhagen, has been able to produce a violent acute gastritis with complete achylia. Thus hæmatogenous toxic gastritis with anacidity is frequent in children. It is usually transient, but is occasionally very protracted, perhaps persisting for life. The hypothesis of a constitutional achylia postulates a certain number of cases of achylia in perfectly healthy infants; 127 infants examined all showed acid secretion. In adults, in the same manner, an achylia develops and sometimes persists after acute infections of the intestines, such as dysentery, typhoid, and paratyphoid fevers. Achylia is very frequent in pulmonary tuberculosis, occurring, as is well known, in 33 per cent. of the cases. Finally, a diminution of secretion, amounting at times to achylia, is seen in the toxæmias of pregnancy, especially eclampsia.

These ætiological factors explain the otherwise mysterious origin of various forms of achylia. The cause is often quite remote; it may be traced to childhood, or may remain unrecognised. The absence of conspicuous causative factors is no argument in favour of achylia being a constitutional congenital lesion.

In contrast to the hæmatogenous toxic ætiology of gastritis is the well-known direct irritation of the stomach mucosa by poorly prepared food, alcohol, certain drugs, &c. Alcoholic gastritis is the typical example. Vogelius found achylia in 50–60 per cent. of cases with advanced chronic alcoholism. But the achylia usually develops quite late, and is preceded by periods of marked stomach symptoms with gradually decreasing secretion. Achylia may appear during these exacerbations, but disappears on diet treatment. If the abuse of alcohol is persisted in, achylia finally becomes constant. It is probable that the hæmatogenous form attacks the entire stomach at once; it is a pangastritis, and for this reason soon produces anacidity. The gastritis from direct food irritation seems to have a longer stage of preserved, and eventually of increased, acidity. Perhaps it is localised at first in the pyloric

TABLE I.

region and later expands gradually over the entire corpus; and not till then does secretion cease. Experimentally Einar Thomsen has produced a typical alcoholic gastritis in dogs. The lesion was first shown by hypersecretion and increased acid values; but after protracted ingestion of alcohol the secretion disappeared and the mucous membrane showed a diffuse extreme gastritis.

A better understanding of the ætiology of achylia is gained by considering its occurrence at the different periods of life. It is quite frequent in children; but in them the secretion usually, if not always, seems to return. In adults its frequency increases rapid with advancing age; in old people it is so freque that Dedichen, in Oslo, found it in 66 per cent. apparently healthy people of 67–92 years. Meule gracht, in Copenhagen, found it in 75 per cent. individuals past 70. In both instances the stu was made on inmates of Old Folks' Homes, w presumably had taken poor care of their teeth a had probably often taken coarse food and alcoh The age-grouping of 400 cases of achylia from o medical clinic was as shown in Table I.

The greatest number occurs in the decade 50–6 and this holds good also, when all cases of fa achylia are separated out, including those whose to acidity with phenolphthalein—after the ordina Ewald's test-meal—was 20 or more. The maximu of false achylia occurs at an earlier date, in the deca 40–50.

A clearer understanding is gained by compari the age-grouping of our 306 cases of achylia wi the age-grouping of 1000 patients admitted consec tively to the hospital. (Table II.)

TABLE II.

The markedly increased frequency of achy in the aged does not support the hypothesis o congenital constitutional cause, but is consist with the anatomical pictures. Throughout life stomach is exposed to injurious agents, either direc or indirectly via the blood. This aggravates existing gastritis, which finally extends over the en stomach and involves such great changes of mucous membrane that achylia is established. older the individual, the more rarely achylia i temporary phenomenon, and the more freque do the anatomical changes terminate in comp atrophy. Partial false achylia is also relatively n frequent in younger patients.

Symptoms of Achylia.

The other argument in favour of a constituti achylia is the relative frequency with which it ex without symptoms. The symptoms of patients v achylia are of two kinds. In one group they partly very serious, and seem to be directly relate the acid insufficiency. They are indirect, inasmuc they apparently originate from the changed condit within the intestinal tract, when gastric secre and subsequent peptic digestion and food disinfec come to an end. As is well known, these sympt are frequent diarrhœa, anæmia, ending as pernic anæmia, combined toxic sclerosis of the Frequently the grave sequelæ of achylia form terminal phase of gastritis, in the same way uræmia forms the end-result of a chronic neph which otherwise, perhaps, gave rise to very symptoms. These, however, are not the sympt whose absence is used as an argument for constituti achylia.

The symptoms missing in some patients with ac are the proper dyspeptic symptoms, as we know th for instance, in alcoholic gastritis. In this condi however, it is well known that pronounced subje symptoms can disappear with the discontinuan alcohol, although a solidly established achylia persist for life, without giving rise to any symp whatever. This is even more common in hæmatoge achylia. The real dyspeptic phenomena—cardi vomiting, eructations, &c., and increased mucus pr

tion—seem to depend more on the inflammation itself than on the lack of secretion. When the gastritis is at rest, there may be an entire lack of symptoms, even though achylia persists. Gastric digestion is replaced by pancreatic digestion, but all the anatomical signs of diffuse gastritis are still present. An achylia acquired in early life can be present for many years without giving symptoms. This is most often seen in hæmatogenous gastritis.

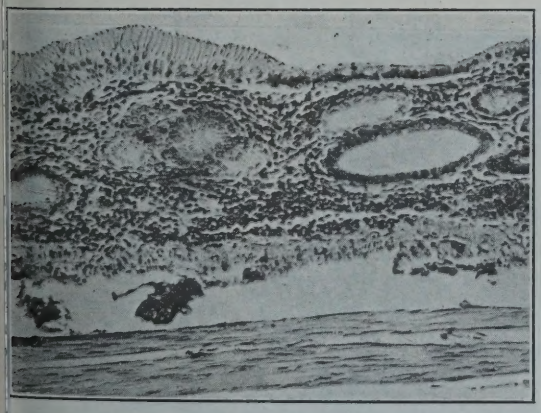
Neither deficient ætiology nor lack of symptoms warrant us in assuming the existence of a congenital constitutional achylia. All the cases are explained most readily and naturally by taking exogenous gastritis as the cause. This does not exclude the possibility that some individuals are more disposed to the disease than others, but as yet there is no material to warrant the conclusion that it is hereditary or familial as, for instance, polydactylism, Huntington's chorea, and the like. It is only natural that such a common disease as achylia should be found in several members of the same family, but this is no proof of heredity. At most it is a sign of increased susceptibility.

II. Acid Gastritis, Pylorus Gastritis.

Since chronic achylia is usually due to gastritis, it is clear that the great significance once attached to this lesion was fully justified. Indeed, the clinical importance of the lesion extends far beyond the achylia.

Increased secretion, hyperchlorhydria, has fared similarly to achylia. At first various authors, especially Korczynski and Jaworski, claimed that an acid gastritis was the cause of the hypersecretion; and Hayem described a special parenchymatous acid gastritis, but its anatomical characteristics could not be upheld. Later the doctrine of hyperchlorhydria as an independent functional, essentially nervous, ailment became the predominant view for a long time. Then it was noticed how often a painful hyperchlorhydria and Reichmann's symptom-complex coexisted with ulcer of the stomach and

FIG. 8.

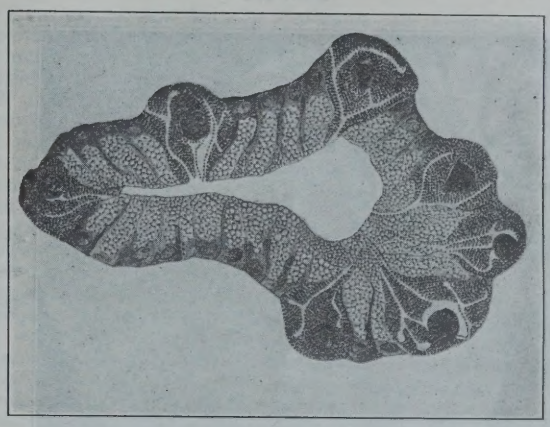


Complete atrophy of the mucous membrane of the stomach. No secreting glands. From a man, 42 years old, who had had gastric symptoms for ten years.

duodenum, and they were taken as caused by the ulcers. That gastritis might be the cause of hyperchlorhydria was less and less thought of.

At the outset it seems probable that a gastritis may exist with the acid secretion intact or increased. We have already mentioned that in many patients the stage of gastritis with complete achylia must have been preceded by a stage, possibly of long duration, in which the acid secretion continued. In alcoholic gastritis a protracted stage of intact or increased acid secretion may often be demonstrated clinically as well as experimentally, and something similar may be presumed to occur in other irritation-gastrites. It is undecided, however, how often a hyperchlorhydria can be referred to a gastritis. The reason for an intact secretion in gastritis may be twofold: the lesion of the mucous membrane may be so mild that no insufficiency ensues, or, more commonly, only a part of the mucous membrane has been attacked. The pyloric region in particular is very often the site of a marked gastritis, while the mucous membrane of the fundus or corpus is but slightly attacked, if at all, and the gastritis may be limited in this way for years, even decades. It is principally

FIG. 9.



Gastric gland, with well-preserved acid cells, in a case of cancer of the stomach which had given symptoms for half a year. Complete anacidity. (Altmann's stain. Einar Thomsen del.)

by the systematic examination of the pyloric part of the stomach after surgical resection that attention has been called to this pyloric gastritis and to its great frequency and great clinical importance. It is only natural that irritation from food—mechanical, toxic, or infectious—should assert itself most effectively in the pyloric region. Here the stomach contents are pressed most forcibly against the wall in a purely mechanical way, while the stomach is working in the effort to pump its contents through the pyloric channel.

Such a localised pyloric gastritis contrasts with the pangastritis of hæmatogenous origin ætiologically as well as symptomatically and anatomically, and deserves most careful attention. It is a juxtapyloric lesion, limited for a long time to the antrum pylori of the stomach and the adjacent part of the duodenum; and its symptoms may be explained by its localisation just as they are conditioned largely by the function of the pylorus.

There is a symptom complex which the Frenchmen Soupault and Mathieu named *syndrome pylorique*. Later on Moynihan gave its principal symptom the name of "hunger pains," which are characteristic of juxtapyloric ulceration, and which he took to be chiefly a symptom of duodenal ulcer. The principal feature of the pyloric syndrome is the late pains or "hunger pains" which set in when the stomach is nearly emptied and persist till more food is taken. Next in importance is increased acidity and, especially, the so-called digestive hypersecretion, which manifests itself after a test-meal in the copious contents of the stomach and, finally, delayed emptying, more or less a gastric stasis. These symptoms are now regarded as conclusive for the diagnosis of chronic ulcer, particularly when larger or smaller hæmorrhages supervene.

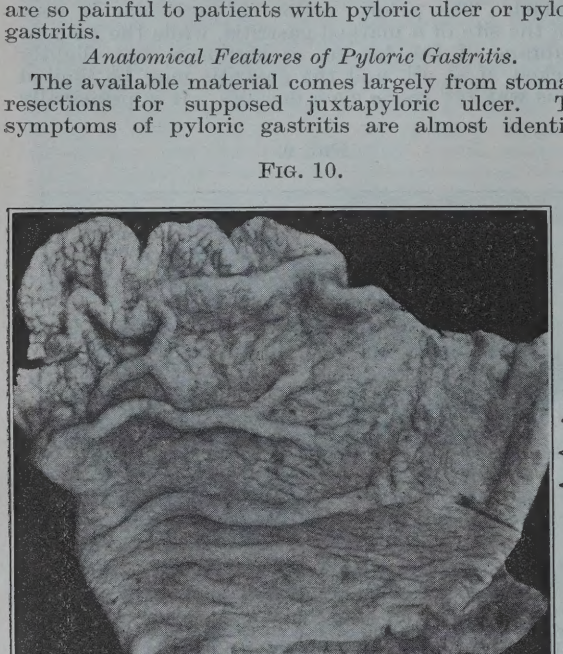
Lately, however, it has become more and more evident that our view must undergo some modification. Since Konjetzny, different clinics have published a steadily increasing number of observations showing that these characteristic symptoms are found not only in juxtapyloric ulcer but also in juxtapyloric

gastritis, especially when the gastritis is complicated by small erosions. The explanation is obvious, for the symptoms must be interpreted as signs of lesions in this particular region. Carlsson demonstrated that periodical contractions take place in the empty stomach. It is these contractions which are so painful to patients with pyloric ulcer or pyloric gastritis.

Anatomical Features of Pyloric Gastritis.

The available material comes largely from stomach resections for supposed juxtapyloric ulcer. The symptoms of pyloric gastritis are almost identical

FIG. 10.



Pyloric part of the stomach, showing gastritis and small erosions. The arrows point to the three erosions.

with those of pyloric ulcer, and a gastro-enterostomy will relieve them in both cases. In the absence of real ulcer, macroscopic examinations of such specimens of the pyloric region frequently shows no change, or at most an accentuation of the mammillated condition of the surface. Many cases, however, show scattered tiny ulcerations or erosions of the mucous membrane (Fig. 10). Frequently these are made more conspicuous by a surrounding elevated fold of mucosa. Sometimes they are very numerous and give rise to the characteristic picture of an ulcerative gastritis. Microscopically the mucosa shows the usual gastric changes: intense infiltration with round cells, numerous large accumulations of cells, and greater or lesser degeneration of the glands, and eventually cystic dilatation. The small erosions or acute ulcers of mucosa are particularly characteristic. The macroscopic ones involve most of the mucosa and are surrounded by densely infiltrated tissue. Some microscopic erosions of the mucous membrane are also found (Fig. 11). These inflammatory features are seen in the pyloric part of the duodenum as well as in the stomach. When the specimens show chronic ulcers, these are not as simple as is often thought. In fresh material the ulcers are more intensely inflamed, and the inflammatory phenomena are not limited to the immediate surroundings but extend over the entire mucosa of the part. Thus the chronic ulcer is surrounded by a marked pyloric gastritis, and sometimes small erosions are seen besides. The conclusion is unavoidable that one or several small erosions in ulcerative gastritis are gradually converted into the typical chronic ulcer, presumably by the joint action of the corroding gastric juice and the mechanical effect of the food passing through the pyloric channel.

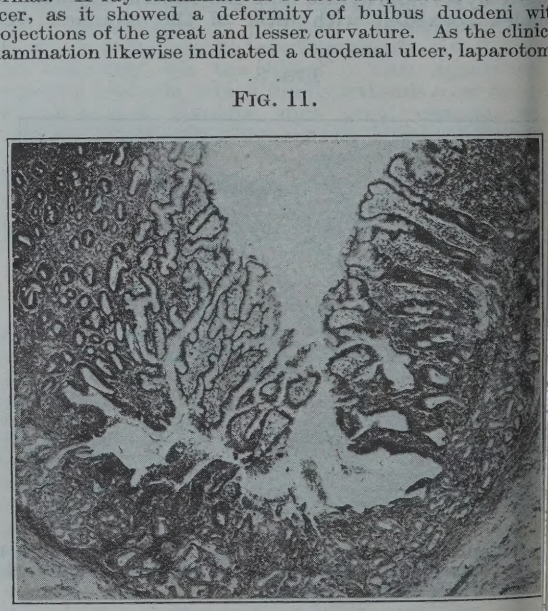
By way of clinical illustration of this lesion I mention two cases, each of which is very enlightening.

Case 1 is that of a young man, aged 25, who for ten years had had pronounced gastric symptoms and had four times been subjected to severe dietetic treatment for ulcer, each time with good but transitory result. The symptoms were hunger pains, appearing about one and a half hours after meals and lasting till the next meal, which relieved them; frequent vomiting; and a dozen small hæmatemeses, rarely more than 1–2 tablespoonfuls. At the hospital frequent occult bleedings in fæces, once melæna. Hyperchlorhydria was demonstrated repeatedly; on Ewald's test-meal, free acid 93, total acidity 106. Fractional withdrawal likewise showed high figures, rapid emptying of food, protracted marked secretion of acid, which still persisted four hours after, and bile influx after two and a half hours. X ray showed a doubtful deformity of bulbus duodeni. The diagnosis seemed clear, and Prof. Schaldemose did a resection of the pyloric part of the stomach and duodenum.

Examination of resected part revealed:—Macroscopical: *No chronic ulcus simplex*, but in the antrum of stomach three to four diminutive erosions, which did not penetrate the mucous membrane and were outlined by slightly elevated edges (Fig. 10). Microscopical: Extremely intense inflammation of the entire resected area and small breaks in the continuity of mucosa with strongly infiltrated surrounding (Fig. 11). In other words, *gastritis* with erosions. The disease had lasted for ten years and had very definite classical symptoms. The small erosions cannot be considered chronic; they are more transitory and changing manifestations of the inflammation. The fundamental (primary) lesion is a marked chronic gastritis, localised to the pyloric portion of the stomach.

Case 2 is that of a man, aged 35, who since his eighteenth year—that is for 17 years—has had periodic attacks of cardialgia, typical hunger pains two hours after meals and at night, relieved by eating. A hæmorrhage in 1924, both hæmatemesis and melæna, wherefore ulcer treatment at hospital. The pains were temporarily relieved but returned in periods. In 1926 confinement to bed and dietetic treatment. In January, 1927, violent pains and marked melæna together with minor hæmatemeses. Admitted to hospital in poor condition; hæmoglobin 72 per cent. The bleeding ceased under ulcer treatment, and the symptoms disappeared save for some delayed pains after light diet. The gastric secretion had previously shown hyperacidity; now it became normal. X ray examinations roused suspicion of duodenal ulcer, as it showed a deformity of bulbus duodeni with projections of the great and lesser curvature. As the clinical examination likewise indicated a duodenal ulcer, laparotomy

FIG. 11.



One of the small erosions seen in Fig. 10.

was done; and as no definite ulcer could be made out the pyloric part of stomach and duodenum were resected. No ulcer was found. In the duodenum there were two pockets resembling diverticula, and small scars between. Unfortunately, death from embolism took place one week later. The other part of the stomach revealed no ulcer. Microscopic examination showed diffuse inflammation of stomach as well as duodenum, but limited to the pyloric region (Fig. 12). The mucous membrane of the corpus was normal, without indication of inflammation.

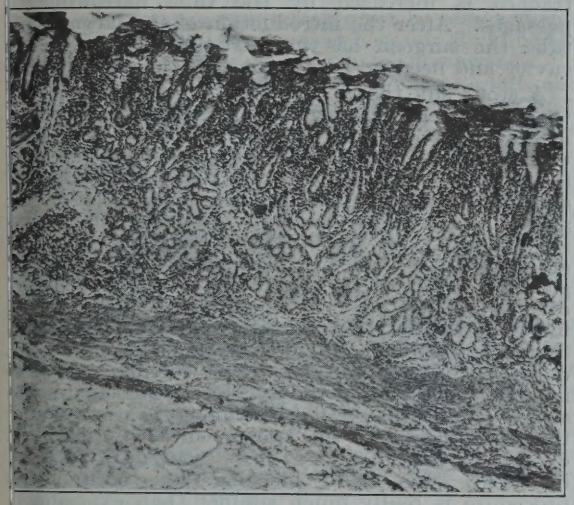
Here we have another case in which the diagnosis of chronic duodenal ulcer seemed certain, and where

he anatomical examination showed no ulcer but a ery marked gastritis localised to the pyloric region. he repeated profuse hæmorrhages and the small cars show that there has been ulceration; but the lcers must have been small and quickly healed acute ulcers." The fundamental (primary) gastritis, n the other hand, has persisted for decades.

CONCLUSIONS.

We realise, then, that the very oldest hypothesis, dvanced by Cruveilhier, is once more coming in the ont; that it is in the gastritis we must seek the rigin of the chronic ulcer; and that the frequent lcerative pyloric gastritis is the cause of the juxta-yloric ulcers. Gastritis is likely to assume that

FIG. 12.



Pyloric gastritis.

dominant position in the pathology of the omach which has been assigned to it from time to me in the past, only to be subordinated to the ory of nervous functional disturbance and chronic mple ulcer.

The whole development of our pathological views this field is a striking illustration of the steady and st important scientific work done in the clinic. e method has ever been that of correlating clinical mptoms with anatomical changes and physiological nctional disturbances. But this progress has been ssible only by long and steady study of patients. e must employ the same exactness in our investiga-ns as do the theoretical explorers; but the bedside st ever be our principal field of research. It oves us humbly to submit to the manifestations of ture in our patients and to seek to grasp the many tures they present. In this manner only do we vance towards our goal, to understand nature and n endeavour to control her.

Clinical Lecture

ON THE TREATMENT OF

CANCER OF THE TONGUE.

Delivered at the Post-Graduate Meeting at St. Mary's Hospital, London, on Oct. 3rd, 1927,

BY DUNCAN C. L. FITZWILLIAMS, C.M.G., M.D., F.R.C.S. EDIN., F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL.

CANCER of the tongue deserves our attention in the first place because of its very rapid course. There is no organ in which the disease is anything like as rapidly fatal as it is in the tongue. Butlin gives 12 months as the average time of survival of the unoperated cases. For the breast the average time of survival of the unoperated case is nearly three times that length. Then in the tongue it is the primary growth, as a rule, that brings about the death of the patient. Such cases have an intensely painful ending. One is able to forget for a time disease in a breast, a gall-bladder, or a uterus, but at no time can one be unmindful of a sore tongue. The patient must constantly breathe and swallow, and the pain therefore is always there. And, finally, there is something which recommends a study of this disease to our close attention, and that is the very poor surgical results we have obtained up to the present time. There is no site in the body in which cancer regularly appears which gives us worse results. Now our methods of treatment have advanced so far, that in future we are going to get almost as good results in the case of the tongue as we do in the case of the breast.

PRECURSORS OF CANCER.

We all recognise that leucoplakia is often a precursor of cancer. Now it does not matter what is the cause of leucoplakia, be it smoking, alcohol, or syphilis, the effect is the same. It used to be fashionable, and perhaps it still is, to say that syphilis is a precursor of cancer. It is not, but its effects on the mucous membrane, the fibrosis after gummata, and the other changes it brings about certainly predispose to the disease, it matters not what is their cause, and that is the only relation syphilis bears to cancer. If the leucoplakia is slight it can be ignored to a very great extent, all we can do is to keep an eye upon it; if, on the other hand, it is severe we can carry out one of the many excellent procedures for the removal of the affected mucous membrane.

Apart from the rarer ways in which cancer of the tongue may start, we can say that the commencement is always in a chronic ulcer, fissure, or sore of some sort, or as a wart, or as a nodule under the mucous membrane. Now we know that the sore and the wart to begin with are in almost every case innocent at first, but they may at any moment develop that peculiar growth of epithelium which determines their cancerous nature. Immediate excision of a wart will prevent cancer developing; similar treatment in any case where there is any sort of a sore on the tongue which shows the slightest sign of becoming chronic, or of not healing on the removal of any visible cause such as a sharp or septic tooth. It can be done under a local anæsthetic, and these little wounds will heal at once. It is always advisable to have the piece of tissue carefully examined by the pathologist. This seems quite a simple and obvious procedure, but it is one which is seldom carried out, and the removal of a chronic sore from the tongue is a very rare occurrence.

SPREAD.

Now once the cancer has started, spread is very rapid. The spread takes place locally and to the glands. Locally the spread is peculiar as it is not apparent. The ulcer may remain quite small, but if sections of the tongue be cut it will be found that the

spread is into the depths of the tongue, down the lymphatics which run along the muscular fibres towards the hyoid bone. Superficially the spread is so very limited ordinarily, we say that if we keep half an inch of sound tissue between the knife and the ulcer that is sufficient, but hitherto we have never laid stress upon the depth we must go, and in depth we must go as far as we can. It is the failure to realise this that is the cause of the local recurrences within the mouth.

Spread to the glands takes place at a very early period, far earlier than in the case of the breast. Why this is so, is apparent when you think of the two organs.

Cancer affects the breast at a time when the organ is past its period of activity; it is an extinct and resting organ; it lies between no muscles which could press upon it and drive out the lymph, which carry away the carcinomatous cells. Infection even of the main axillary glands is therefore comparatively late. In the tongue the condition of things is quite otherwise. There is no period of life in which the organ is past work; it is always actively used for speaking, mastication, and swallowing. It is a purely muscular organ, and each contraction pumps the cells along the lymph channels to the glands, so that their infection must be very early brought about. Not only so, but as the net work of lymphatics is so ample in the neck, the infection is often very widespread at an early date.

OPERATIVE TREATMENT.

In dealing with the treatment of cancer of the tongue these things have to be taken into consideration. The ordinarily performed operation is badly planned; inadequate to the last degree, its results are disheartening; it should be given up.

In the case of a bad leak of water the first thing to do is to turn off the water at the main and then deal with the water which has escaped. In cancer we want to remove the source from which the cancer cells are flowing; we therefore have to deal with the primary growth first; later we can deal with the glands into which the cells have escaped. I state this because lately it has become more and more the fashion to deal with the glands first and then to remove the growth at a later date. Now if you remove the glands first the lymph flows from the cancer just the same, and in the weeks which intervene between the two operations the cells of the growth are carried by devious passages to other glands on the same and on opposite sides of the neck.

The only reason why the operation is done in the wrong order is that intra-oral operations are most distressing, inflammation in a part such as the mouth which cannot be kept at rest is very painful, and the whole procedure is so trying that one is afraid that the patient will not face the second and equally necessary operation of removal of the glands. Most of this unpleasantness can, however, be done away with, as I shall show, so that even this reason no longer carries weight.

If the operation is to be done in two stages the neck should be left severely alone, and therefore ligature of the lingual artery is to be avoided; it is an obsolete procedure never needed, and should no longer be performed. The incision in the neck and the clearing away of a few glands round the carotid is not the radical clearance of the glands which modern thought demands, and merely lays down fibrous tissue which renders subsequent dissection very difficult. A radical clearance of the glands with the certainty of infection of the area from the mouth is not to be thought of.

The First Operation.

At the first operation, therefore, all that is to be done is to remove the growth, and this should be done in the following manner. I shall omit the preliminaries which it is necessary to follow, and the measures taken to reduce oral sepsis.

The patient is anæsthetised in the ordinary way. A small stab wound is then made through the crico-thyroid membrane and a laryngotomy tube inserted and the anæsthetic is subsequently given through this. The smaller the stab wound and the tighter that the tube fits the better; the pressure will prevent all bleeding. On no account should intratracheal ether be given. The danger of the operation being broncho-pneumonia, what better method can be thought of for producing it than rubbing a catheter over a septic cancerous ulcer and then passing it down into the trachea? The introduction of the tube, too, is not always so easy in a tongue which cannot be drawn freely from the mouth, and considerable bleeding from the ulcer may occur in its introduction. The tube is often inserted before the patient is deeply under, and struggling on the part of an old and often broken-down patient is not the best preliminary to a trying operation. Moreover, the pharynx cannot be plugged, and the danger of fluids passing into the trachea is increased by the tube narrowing the passages. After the introduction of the laryngotomy tube the surgeon has unrestricted use of the oral cavity and need no longer consider the anæsthetist.

A stout silk thread is placed through the front of the tongue and another can, if necessary, be placed behind the growth and used as tractors. The pharynx is then plugged with marine sponges to which a string is attached; no fluids can then pass into the pharynx and the danger of broncho-pneumonia is past. The growth, as we have already said, does not spread superficially, and half to three-quarters of an inch are considered sufficient distance to keep from the growth. The mucous membrane below the growth is divided as far back at the anterior pillar of the fauces and the stylo-glossus muscles which constitute that pillar exposed and cut through. This having been done, the tongue can be drawn further out of the mouth. This will put the hyoglossus muscle upon the stretch. A director or flat instrument is inserted under this structure and the muscle divided. This will expose the lingual artery; it is secured, divided, and ligatured. No more bleeding can occur. The procedure is really much simpler than exposing the artery in the neck. Definite flaps of mucous membrane are then fashioned so as to leave sufficient to cover the stump of the tongue, and the growth is removed bearing in mind the depth to which the growth may have penetrated.

Having stayed all bleeding the flaps of mucous membrane are sewn with catgut over the raw surface which as a rule can be covered completely. The sponges are removed from the pharynx, the patient allowed to come round sufficiently from the anæsthetic to enable him to cough—a most important point—as after the coughing reflex is established and nothing is likely to pass down the wrong way. For this reason morphia should be avoided as it dulls the coughing reflex. The laryngotomy tube can then be removed and a small dressing placed over the tiny wound. The patient lies in bed half on his face, so that saliva will flow naturally out of his mouth, and on no account will any swabbing of the interior of the mouth be allowed for fear of disturbing the stitches. For the first few days plentiful rectal saline should be given, but I do not need to go into the nursing details with you.

The recovery is most rapid; there is no raw ulcerating surface in the mouth to heal, there is little inflammation, and consequently little pain. In fact the operation has been robbed of most of its unpleasant features.

That, shortly, is the operation, and I need not elaborate it to point out that both sides of the tongue can be removed at the same time. I must emphasise, however, that the tongue should never be split in bilateral removal. You are removing it because both sides are affected; if you split it as used to be recommended, you must cut through the cancerous area and cells will escape.

The Second Operation.

Two to three weeks later the glands of the neck are attacked. During those weeks nothing is to be

feared from them; if badly infected they are blocked and no lymph is passing through, in any case the source from which the lymph flows has been removed and no fresh cells have been implanted. But for the continual growth of the cells they are as they were at the time the tongue was dealt with.

An incision is made down the whole length of the anterior edge of the sterno-mastoid muscle. From the middle of this incision a second one passes up to beneath the point of the chin. Further incisions can later be made at each end if needed.

The first incision is deepened so as to expose the external carotid artery which is secured and divided between two ligatures. This greatly simplifies the procedure. The whole of the gland bearing fascia at the side of the neck, together with the submaxillary gland and the sterno-mastoid muscle, is removed. If the glands are badly infected they will be adherent to the internal jugular vein which must be removed too. In this case the dissection is best begun in dividing the sterno-mastoid above and working downwards. If the glands are not adherent, the vein can be left, and it does not matter at which end one begins. In deep dissections of the neck high up much more room may be obtained if the angle of the jaw is sawn through and removed. Handling of the glands should be carefully avoided. They should not be touched, nor held, as pinching, squeezing with forceps, or dividing with the knife favour the escape of cancerous cells which would be sown on the raw surfaces and so cause recurrence. All the glands from the anterior and most of the posterior triangles can thus be removed.

I am not in favour of block dissection of both sides of the neck. It is, in my opinion, sufficient to remove those from the affected side and to watch the opposite side. The glands become infected direct from the tongue, one becomes infected and blocked, and as no further lymph flows through it no cells can be carried from it. The lymph being deflected through other glands, other glands become infected, but all directly from the original growth, not from previously infected glands. It is sufficient, therefore, to watch the opposite side and examine it systematically once a month and deal with infection if it arises.

That, shortly, is the modern method of dealing with cancer of the tongue by means of operation.

APPLICATION OF RADIUM.

Of late, however, another method of treatment has been used with great success, and that is the treatment of primary growth by radium.

The method of procedure is as follows: Novocaine is injected into the lingual nerve on both sides as it lies under the mucous membrane on the inner side of the jaw. This is a simple and satisfactory proceeding. There are very many ways of applying radium. Here are the tiny glass needles containing emanations which are inserted and left in permanently. There are the fairly large doses of radium enclosed in tubes of platinum to screen them, which are left in for perhaps 24 hours; and there are the small needles of platinum containing doses of 0·2 mg. which are inserted and left in for a week or more. Of these methods the last seems to answer in much the most satisfactory manner. It is the method which has been used by Prof. Regaud in Paris for some years, and anyone who has seen his results will be convinced of its merit. The needles can be an inch or an inch and a half or two inches long. Each needle is threaded with a piece of fine wire and a piece of Japanese silkworm-gut. They should be inserted at about half inch intervals round the growth and should be pushed straight in towards the root of the tongue. When driven home the silkworm-gut is threaded on a needle and a stitch put through the mucous membrane of the tongue, tied, and cut short. Each needle is treated in the same manner. The wire threads are twisted up and threaded through a thin piece of rubber tubing which is brought out of the mouth and secured to the cheek with plaster. In this way the needles are doubly anchored and should be examined daily to see that they are not working loose. Each needle is worth some £300 to £400, so that precautions are necessary.

The needles are left in for at least a week and are then removed. A little inflammation is seen in a few days and usually small areas of necrosis appear where each needle was inserted. The ulcer shrinks and its surface becomes covered with a white slough, and soon begins to heal over. The induration and stiffness of the tongue begin to disappear, and in successful cases the whole growth may have dissolved in five to six weeks. If the dose has not been sufficient a second may be needed, but will have less effect than the first dose. Overdoses may produce a most persistent form of tissue necrosis and transform the carcinomatous ulcer into a most intractable radium sore which may be painful. Necrosis of part of the jaw sometimes takes place, and the patient should be warned that his moustache will fall off, at all events on that side; this will save him the trouble of shaving for some time.

Attempts have been made to destroy the cancerous glands of the neck by radium either inserted or applied over certain coverings to the outer side of the neck. The glands can be made to get smaller and to disappear, but in my experience only for the time being. I have had cases where large masses of glands on both sides of the neck have completely disappeared for more than a year. Probably a combination of the two methods is at the moment the ideal one. Even at Prof. Regaud's clinic block dissections are the rule.

You will expect me to mention the method of treatment by diathermy, and I will do so, but merely to warn you to avoid it if possible, except in inoperable cases where you cannot get at the growth, and probably in those cases radium is a better weapon to use. It is curious how even surgeons can be swayed by fashions and vogues. Diathermy is one of them. It came in some years ago and had a great vogue; this is quite past among those who have used it much. It is invaluable in certain cases and almost fatal in others. There is nothing mysterious in it; a cold current passes into the tissues; the instrument does not get hot, it is the tissue resistance which creates the heat, and this cooks the tissue. Great experience is needed to get the best results. The cooked tissue then rots off, and in a septic cavity such as the mouth you can imagine the state of affairs after a few days. The same thing can be produced by tying a piece of cooked steak firmly to a tooth and allowing it to rot away. It is no wonder that septic pneumonia frequently accompanies it. It is often, too, very painful, as in all gangrenous processes a line of demarcation must form between the living and the dead and the resulting inflammation is difficult to bear in a part like the mouth, which cannot be kept at rest.

RESULTS.

As to the results it is difficult to speak with certainty as these methods have not been tried very long. There is no doubt, however, that we have improved our position out of all recognition in the last few years. There is not much difference now between the results obtained by operation alone and those obtained by radium and operation. The former are still slightly the better. We can reasonably expect 25 to 30 per cent. of three-year cures at the moment, but here, as elsewhere, everything depends upon the time at which the cases are diagnosed and treated. In really early cases I think 40 to 50 per cent. of three-year cures should easily be obtained, and 25 to 30 per cent. five-year cures. This is a great advance on the previous figures.

PAYING PATIENTS IN HOSPITALS.—The Special Committee of King Edward's Hospital Fund, which is inquiring into the subject of hospital accommodation for paying patients, has just taken the evidence of Dr. S. S. Goldwater, director of the Mount Sinai Hospital in New York.—The governors of Swansea Hospital have decided not to admit or assist with advice or treatment any person who is "able to pay fully for the same."

DETERMINATION OF COMPATIBILITY IN BLOODS.*

BY S. C. DYKE, D.M. OXF., M.R.C.P. LOND.,
CONSULTING PATHOLOGIST TO THE WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL.

IN the following remarks the classification of the blood groups devised by Moss [1] is used throughout. Group I. consists of bloods wherein the red cells carry both the A and B agglutinable factors of von Dungern,[2] Group II. of those wherein the red cells carry A alone, Group III. of those carrying B alone, and Group IV. of those wherein the red cells have no agglutinable factor. The term agglutinable factor is hereafter replaced by the term "agglutinogen," now in general use in America. This term is open to obvious objections, but is less cumbersome than the alternative expression.

In the selection of donors for transfusion the first step is the identification of those individuals whose blood is compatible with that of the proposed recipient. A compatible blood may be defined as one which can be introduced into the circulation of an individual without giving rise to disturbances due to differences in the agglutinogen-agglutinin formulæ of the two bloods. There are other reasons for results unpleasant to the recipient following blood transfusion. Various diseases, such as syphilis or malaria, may be and have been inoculated with blood from an infected donor; in another category fall the immediate unpleasant or even fatal results which may follow too great or too rapid a transfusion. Still another class of reaction, and one very commonly seen, is that depending on the use of water which, though sterile, is not free from bacterial protein. Certain unpleasant reactions are ascribed to the use of sodium citrate as an anticoagulant, though my own experience would lead me to believe that the water is more often at fault than the citrate dissolved in it. However, I am only concerned here with the means of identifying those bloods which, when introduced into the circulation of another individual, will produce no ill-effects due to interaction between the agglutinogen-agglutinin complex of the two bloods.

As is well known, the transfusion of an incompatible blood is invariably followed by hæmolysis, which shows itself, if the recipient lives, by jaundice, hæmoglobinuria, and the return of the blood count within a few hours to the level at which it stood before the transfusion. Hæmolysis may be regarded as the criterion of incompatibility, and it is necessary to select donors whose bloods are so constituted as to be incapable of causing hæmolysis in the circulation of the recipient. The selection of donors, then, resolves itself into the question of how to identify those bloods which are incapable of reacting with the blood of the recipient in such a manner as to produce hæmolysis. Hæmolysis is a reaction that is comparatively rarely seen outside the body. Agglutination, however, is common. Landsteiner and Leiner [3] produced satisfying evidence that hæmolysis and agglutination are components of the same reaction; they showed that hæmolysis is always preceded by agglutination, and that in the absence of active complement the reaction will not proceed beyond this first step. Jones [4] has made new observations in this direction and confirmed the old. In tests outside the body the criterion of incompatibility between two bloods must be either hæmolysis or agglutination on bringing them together. Experience, for the most part gained during the war, has clearly shown that a blood, the serum of which is capable in vitro of agglutinating the red cells of the recipient, may be infused without harmful results. Hæmolysis with its attendant evils follows upon the injection of a blood the red cells of which are in vitro capable of being agglutinated by the serum of the recipient. This phenomenon is probably explained by the fact that on infusion the plasma of the donor's blood is so immediately and so greatly diluted by the recipient's plasma that the titre of such agglutinins as it may contain is reduced to an ineffective level. The potentialities for hæmolysis and its attendant evils are present; in actual practice it rarely, if ever, occurs. In practice, therefore, an incompatible blood may be described as one, the cells of which are capable of agglutination in vitro by the serum of the proposed recipient, and the selection of a donor resolves itself into the question of the identification of those individuals whose red cells are incapable of agglutination in vitro by the serum of the proposed recipient.

Until recently this appeared to present no difficulties. The theory of von Dungern offered a universally accepted explanation of the blood groups; anyone possessed of sera of Group II. and III. could place any given blood in any one of Moss's four groups, and the compatibility relationships between the four groups appeared to be perfectly understood. In Moss' Group IV. there was believed to exist a class of persons ordained and ordered of God to give their bloods to anyone without putting pathologists to any trouble beyond that of identifying them once and for all.

The Multiplication of Agglutinogens.

These beliefs had only just been accepted when their bases were questioned almost simultaneously by Coca and Klein [5] and by Guthrie and Huck.[6] Both these pairs of workers studied bloods the reactions of which they believed to be explainable only by postulating a further agglutinogen with its appropriate agglutinin. Guthrie and Huck called their newly found agglutinogen "C"; Coca and Klein described theirs as "X." More recently Landsteiner and Witt [6a] and Simson [7] have also described bloods which do not fit into any of Moss's groups and the constitution of which they believe can only be explained by the presence of yet another agglutinogen. Finally Guthrie and Huck have increased the complexity of the matter still further by describing "D" and "Q" agglutinogens. Even one further agglutinogen makes the whole constitution of the blood groups highly involved; the number of possible permutations and combinations of three agglutinogens and three agglutinins is large enough.

The publication of the work of Guthrie and Huck and of Coca and Klein led various pathologists to reinvestigate von Dungern's hypothesis as to the existence of only two agglutinable factors. In this country Jones and Glynn [8] have devised a quantitative method for studying the titre of agglutinogen-agglutinin reactions, and on this basis have searchingly investigated the interactions of 40 individual bloods. They found six bloods giving anomalous reactions, but saw no reason for the postulation of further agglutinogens, other than the original A and B of von Dungern. Similar conclusions as to the sufficiency of von Dungern's original hypothesis have been reached by Mino,[9] Lattes and Cavazutti,[10] Hubener,[11] Schiff,[12] and Flagairolle,[13] and also by myself.[14] Lattes and Cavazutti summarise the causes which they believe have led various workers to postulate the existence of agglutinogens other than A and B as follows: (1) low agglutinogen-agglutinin titre; (2) pseudo-agglutination; (3) failure of complete adsorption in adsorption experiments.

My own experience leads me to believe that the first and third factors are capable of explaining most of the results which have led to the postulation of agglutinogens other than A and B. The existence of great differences in titre both of agglutinogen and agglutinin was, I believe, first pointed out by myself in 1923.[15] I have recently satisfied myself that in some bloods in which both agglutinogens were present the agglutinogen titre of one might be so low as to escape detection altogether except by adsorptic methods, and that in such bloods the agglutinin homologous to the low titre agglutinogen might be present. As an example I may cite one of the six anomalous bloods recently described by myself.

* An address delivered before the summer meeting of the British Pathologists Association.

Blood No. 6.—Red cells were agglutinated by ten Group III. sera. They failed to agglutinate with the two sera of Group II., but were powerfully agglutinated by two other sera of Group II. The serum of this blood failed to agglutinate all cells of Group II. or III. with the exception of one specimen of Group III., with which it gave a trace of agglutination. Absorption of a Group IV. serum by the cells of this blood resulted in the complete removal of both agglutinins *a* and *b*, as shown by subsequent tests against cells of Groups II. and III. The red cells of this blood evidently contained both the agglutinable factors A and B, and so far as the cells were concerned it was therefore of Group I. The failure on the part of two of the Group II. sera to reveal the factor B may be accounted for by a low titre of the agglutinin *b* in these sera and a low concentration of the factor B in the cells. That these sera were deficient in the agglutinin *b* was shown by titrating them against several samples of red cells of Group III. In no instance did agglutination take place in dilutions over 1 in 10 of the serum. In spite of the Group I. constitution of its red cells the serum of this blood contained agglutinin *b*, and in respect of its serum it belonged to Group II. The fact that auto-agglutination of the red cells did not occur in this blood was presumably due, as in the further cases described, to the relatively low titre of the agglutinin and the small proportion of the corresponding agglutinable factor in the cells.

By ordinary grouping methods this blood, though actually Group I., was relegated to Group II. It is significant that these as modifications of Group II. that most of the anomalous blood have been described.

The implications of the observations of Jones and Lynn, Mino, Schiff, and myself may be summarised in the statement that many bloods apparently of Group II. or III. really belong to Group I. The rarity of Group I. individuals in the general population would, on this view, be apparent rather than real. This is supported by the fact, pointed out by myself and Hodge,[12] that Group I. bloods are apparently much rarer than they should be on strict Mendelian grounds.

Unreliability of Grouping Tests.

It is obvious, therefore, that in the present state of knowledge no reliance can be placed upon grouping tests alone as a criterion of compatibility. If the views of Guthrie and Huck and those who think with them are correct, almost infinite numbers of groups must exist, and universal donors must be few and difficult to identify. If, on the other hand, the view be accepted that anomalies are explicable on differences of agglutinogen-agglutinin titre alone, simple agglutination by itself can no longer be regarded as a satisfactory means of assigning an individual to any group. Elaborate adsorption tests are demanded, for which there is usually no time when a donor is being selected.

Furthermore, the grouping of a blood demands the possession of known group sera of high titre, which are not easily obtained. In Group II. the difficulty is not great, but in Group III. it is a different matter. In this respect my own experience is illuminating. For several years I obtained all the Group III. serum which I required from a single donor. This serum was exceptionally high titre, and by using it in a long series of experimental agglutinations and adsorptions I was able to satisfy myself that it was reliable. While using this serum for grouping I chose all donors on the grounds of group affinities, without recourse to direct matching. In a large number of transfusions no incompatibility trouble occurred. About two years ago this source of Group III. serum failed me; I obtained the serum from two other sources and carried on as before, selecting donors on the strength of their group alone and without matching. Before long two cases occurred in which it was obvious that incompatible donors had been used. In both there was complete hæmolysis of all the infused blood, though happily without serious effects so far as the patients were concerned. Investigation of the two Group III. sera used showed that the titre of each was far below that of my original serum of this group. The donors and recipients in both these cases were supposedly of Group IV. I have no doubt now that in both these cases the donors were actually of Group II., but that the agglutinogen titre of their cells was so low as to result in no agglutination when brought into contact with the Group III. serum used.

Direct Matching of Blood.

In view of the difficulty of obtaining Group III. sera of known high titre, I came to the conclusion that the only safe and satisfactory way of determining compatibility is by direct matching of blood. Since adopting this measure there has been no further hæmolysis after transfusion, and such reactions as have occurred have only been of the type attributable either to too great or too speedy infusion of blood or to the use of contaminated distilled water.

The actual technique of typing used is that which I devised some years ago in investigating blood groups, and is practically the same as that adopted as a standard by the American Society of Immunologists.

A few c.cm. of blood are drawn direct from the recipient by venipuncture into a centrifuge tube. Clotting is hastened by placing it in the incubator, and the serum is spun out and then pipetted off into a sterile test-tube and kept in the ice-chest until required. When repeated transfusions are anticipated a few drops of chloroform are added; the serum will then retain its agglutinating properties for years. Blood is obtained from the proposed donors by capillary puncture in the finger or ear by a bayonet-pointed surgical needle. This blood is diluted to the extent of 1 in 100 with normal saline in an ordinary Thoma red cell pipette. This dilution represents the optimum degree for the blood of normal adults. For anæmic persons a lesser degree of dilution may be advisable, but such persons should obviously not be used for donors. Once the blood is drawn into the pipette and mixed with the saline it may stand for many hours without deterioration. Each pipette of diluted red cells is marked with a number corresponding to the entry in the laboratory day-book of the donor's name and address.

For the actual matching one plane and one hollow-ground slide are prepared and each is marked with the identification number of the blood to be tested. On the plane slide is placed one drop of the recipient's serum, and to this is added one drop of the donor's red cell emulsion. Serum and cells are thoroughly mixed with a clean platinum loop. With the loop a drop of the serum cell mixture is transferred to a cover slip and a hanging-drop preparation made in the usual manner. Both the plane and the hollow-ground slide preparations are allowed to stand for ten minutes at room temperature with occasional shaking before a reading is made.

Usually if agglutination is to take place this can be detected within a few minutes on the plane slide by the naked eye. Minor degrees of agglutination are, however, easily missed and the slides are always examined microscopically. No decision as to compatibility is given until the preparation has stood for one half hour at room temperature. The hanging-drop preparations should always be put up because in some cases, particularly when the temperature of the laboratory is high, evaporation may have proceeded to such a degree at the end of half an hour as to render the readings of the plane slide preparation doubtful.

In fresh serum agglutination may not infrequently be replaced by hæmolysis. This phenomenon is readily appreciated under the microscope, though it may escape observation on naked-eye examination alone. As pointed out above, its significance is the same as that of agglutination so far as the compatibility of a proposed donor's blood is concerned.

The dilution of the donor's plasma in the above technique has the advantage of inhibiting rouleau formation. The possible presence of auto-, hetero-, and pseudo-agglutinins has been a bugbear to many workers in this field. It has been shown by many authors that such interfering agglutinins when present exercise their effects only at low temperatures (Landsteiner and Witt [17]). It is for this reason that the preparations are left at room temperature and not placed in the ice-chest, as recommended by Guthrie and Huck and some other workers. Greater safety might be achieved by placing the preparations in the warm incubator, but I have not found this necessary.

This technique is, I believe, as simple as possible, and at the same time as safe, or possibly even safer, than the more elaborate procedures involving macroscopic agglutination or the washing of the donors' red cells. For the reasons given I do not think it necessary to test the red cells of the recipient against the serum of the donor. It is theoretically conceivable that trouble might arise from neglect of this precaution, but in practice I have never known it happen.

Conclusions.

In the selection of a donor for transfusion the one essential test is that of the recipient's serum against the red cells of the proposed donor, and this test should be carried out carefully and according to a standard technique. On considerations of scientific interest it is very desirable that grouping tests should be performed on recipient and donor alike, but little importance should be attached to them until we are more certain as to the constitution of the groups. In transfusion services the mere fact that a person is known to be of Group IV. can never justify the assumption that his blood will suit any and every recipient. Matching tests are as necessary for "Universal Donors" as for other individuals. It is probable that the blood of individuals of Group IV. will be compatible with that of more recipients than that of persons belonging to other groups, and they are therefore desirable persons to have on the roster of a transfusion service. With the recognition of the fact that matching must always precede a transfusion there is, however, no necessity for the exclusion of persons belonging to other groups from such a service.

INTERMITTENT CLAUDICATION AND ITS TREATMENT BY DIATHERMY.

BY A. WILSON GILL, M.D. EDIN., M.R.C.P. LOND.,
HONORARY ASSISTANT PHYSICIAN, NORTH STAFFORDSHIRE ROYAL INFIRMARY;
AND
L. NEWELL MOSS, M.R.C.S. ENG., D.M.R.E. CAMB.,
LATE HOUSE PHYSICIAN TO THE INFIRMARY.

THE term "intermittent claudication" was first employed by H. Bouley in 1831 for a condition of lameness in horses where partial stenosis of the abdominal aorta and iliac arteries was present. Charcot, in 1858, fully described similar symptoms in a man where, as a result of a gunshot wound, an arteriovenous aneurysm was produced and the arterial trunk was in part obliterated. He therefore associated the symptoms with ischæmia, and there is much to support this explanation.

Patients seen in clinics generally show some atheroma and hypertension and are between the ages of 40 and 60. Most of them have other indications of bad circulation, such as angina pains, dead fingers, dyspnœa, &c. In several cases, however, the evidence of arterio-sclerosis is not very obvious and many cases have no hypertension. The ischæmic theory is further supported by the rapid recovery after a short rest and by the observations of D'André Thomas and Lévi-Valensi showing that during the attacks there is a diminution of temperature in the affected part. Babinski and Heitz showed that immersion in hot water during the attack increased the pulse oscillations and cut short the duration of the pain. Th disease most commonly affects the lower extremities but also occurs in the arms and back and, les commonly, in the vessels of the brain.

The early symptoms of the crural type are tired ness, light cramp in the calves, and sensations c heat and cold, usually in the toes but sometime throughout the leg. The usual symptoms of claudica tion of the nervous centres include temporar paralyses, headaches, fatigue, inability for effor alterations in character, attacks suggestive c migraine, changes in memory, aphasia, amblyopi and blindness, and narcolepsy. In all cases th symptoms are increased by exertion, by load, uneve ground, indigestion, and hurry; they are usuall worse in winter. The condition in the leg sooner c later increases in intensity until agonising cram develops; some cases progress to gangrene. In th brain some permanent organic change, such a hemiplegia, is liable to occur. Other cases develo the full clinical picture from the first without an preliminary warning.

As a rule, the affected extremity shows som mottling of the skin or vein streaks, a variation i local temperature, and a diminution or abolition the pulse in the distal arteries. Shrinking of th retinal vessels has occasionally been noted in th cerebral attacks. Other cases fail to show an objective signs, and pulsation remains present. The facts favour the explanation of a definite anatomic stenosis, probably with a vasomotor element causi temporary spasm of the arterioles.

In 1905 Ramsey Hunt wrote: "Three facto must be recognised in the production of claudicati ischæmia—one, constant and organic in natu diminishing the calibre of the vessels; and tv factors, inconstant and functional, the tendency vasomotor spasm and the increased demand up the circulation of the part during activity." Comro objects to the name in so far that the term "int mittent" is misleading. He points out that or the symptoms are intermittent, the anatomi stenosis which is responsible for the excruciati pains being constant. He therefore suggests t term "paroxysmal." Other terms suggested ha been dysbasia intermittens angiosclerotica (E 1898), angina cruris (Walton and Paul, 1902), a paroxysmal angiospasm dolorosa.

Ætiology.

Much doubt still exists as to the ætiology. H was the first to stress the importance of tobacc of 172 cases only 7·4 per cent. were non-smokers a 50 per cent. were heavy smokers. Most writers ag with this statement, although Vaquez,[2] as recently 1925, stated that too much stress had been laid tobacco as a factor. Guilleminot[3] thinks toba very important, and quotes Meyer's statement th a diagnosis of intermittent claudication in a n smoker is wrong. Parkes Weber[4] states that in disease thrombo-angiitis obliterans, common in m Jews, of which intermittent claudication is a sympto "he has never come across an instance of this dise in a woman, nor yet in a man who has not, or h not been a free cigarette smoker."

Other ætiological factors include alcohol, syphi gout, and diabetes. Déjerine believed that syph was nearly always an important factor, although L and Déscoust[5] found no improvement from a syphilitic treatment and could trace no importanc diet. Recently influenza has been blamed as the or provocative cause. Other considerations are stress and strain of life, infectious disease, tea coffee, &c.

Philips and Tunick[6] found a persistent leucocyt in many cases of thrombo-angiitis obliterans, sugg ing a chronic infection, although they also belie that tobacco produced alterations in the blo vessels, either directly by making them m susceptible to inflammation and thrombosis indirectly by effects on the vasomotor appara Meyer in several cases found a hyperglycæmia.

The essential cause of the disease, therefore, like that of thrombo-angiitis obliterans, remains unknown.

The following case shows the disease primarily affecting the lower limbs, progressing to gangrene, and secondarily involving the cerebral vessels, with frequent attacks of hemiplegia and aphasia. The cerebral attacks are similar to those of two cases of transitory hemiplegia occurring at ages 57 and 71, reported by Langwill [7]; in neither was there any evidence of hypertonus or arterio-sclerosis.

A married Englishman, aged 59, a jeweller's assistant, first consulted one of us (A. W. G.) in August, 1924, complaining of a feeling of cramp in the left foot and calf on walking short distances, passing off after a brief rest, and recurring after another short distance.

Despite treatment as hereinafter described, the condition steadily became more severe until Oct. 5th, when he had intense pain in the left leg and took to his bed. On Oct. 6th the left leg below the knee was cold and dead and no pulsation could be felt in the femoral or popliteal arteries or in the dorsalis pedis artery. The leg was wrapped in cotton-wool and surrounded with hot-water bottles, but there was no return of pulsation. He was confined to bed for several weeks, and in January, 1925, definite dry gangrene commenced in the great toe, and on Feb. 26th the leg was amputated at the seat of election by Mr. Reginald Alcock. Unfortunately, no pathological examination was made of the blood-vessels of the leg removed. Healing was rapid except for the subsequent removal of a small sequestrum.

He remained well and had no further trouble until the night of June 14th, 1926. He awoke suddenly with a feeling that his whole body was dead. He could only move his head and upper part of the trunk. His mental faculties remained unimpaired and there was no pain though he was acutely anxious. He failed to get out of bed and could not cry for help, but after a few minutes the attack suddenly passed off and he was able without difficulty to move freely. His alarm passed away and he returned to bed and slept well till the morning.

On June 19th he had a similar attack and a third attack in the forenoon of June 20th while at rest in bed. The fourth attack occurred during dinner the same evening; the weakness was particularly marked over the right arm and leg and there was complete aphasia, except for an inarticulate noise, but consciousness remained throughout. This attack lasted about five minutes and was followed by six similar attacks the same evening, all beginning with a slight warning, so that the patient could declare that an attack was coming. A minute afterwards the face became pale and more or less complete hemiplegia set in, involving the right side of the face, arm, and leg. He remained conscious but was obviously alarmed, and endeavoured to speak and answer questions but only achieved an unintelligible jargon. The attacks passed off completely except for a sense of weakness and weight in the right arm, and he began to notice that the finer movements of his fingers were at fault and writing became difficult. His script was shaky, uneven, and difficult, similar to that of writer's cramp, so that even tremendous mental effort failed to complete a word. The movements of the right leg were free while lying on the bed or sitting in a chair, but when standing no degree of effort could move the leg even when he was supported by crutches.

During the attack the right plantar reflex became a doubtful extensor and was quite definitely flexor after the attack. The ankle-jerk was present, but the knee-jerk could not be elicited owing to bony ankylosis of the joint.

On July 7th, 1926, he was admitted to the North Staffordshire Royal Infirmary where he remained an in-patient until August 7th.

Previous History.—As a child he had a tuberculous right knee which has been completely ankylosed for many years as a result of fixation treatment. This is his only illness. He has led a quiet life, having his meals at regular hours and in no hurry. He drinks a pint of ale daily and a very occasional glass of spirits. There is no history of syphilis. He smokes ten cigarettes daily and about 2 oz. of tobacco in pipe per week. He was able to walk good distances and did a 10-mile walk every Sunday.

Family History.—His father died, aged 81, from cancer of the stomach. His mother died, aged 87, from cerebral thrombosis after repeated minor attacks of hemiplegia. His wife is healthy and has had no miscarriages. There are two daughters and one son alive and all in good health.

Condition on Admission.—His general nutrition was good. There was no anæmia. Apart from the amputation of the left leg and the ankylosis of the right knee, there was little to note on external examination. The teeth were bad, showing much dental caries and pyorrhœa. The heart showed no enlargement; the action was regular, 72 per minute, and no bruits were heard. The systolic blood pressure was usually about 130 mm. of mercury. No atheroma was noticed. The electrocardiogram showed no special features. The lungs and abdomen appeared normal. The cranial nerves were all intact and no weakness of the eye muscles was noted. Examination of the retinæ was done by Mr. S. McMurray who reported: "There is no evidence of arterio-sclerosis of the retinal vessels." There were no sensory changes to touch, heat or cold, and no astereognosis. The plantar reflex was flexor. The ankle-jerk was present and no ankle-clonus could be elicited. The abdominal reflexes could not be obtained. The arms were thin and there was some slight wasting of both thenar eminences and of the interossei muscles. The grip of the right hand was enfeebled. There were no tremors and no paralysis. The Wassermann reaction of the blood was negative.

The blood picture was: red cells, 7,200,000; white cells, 27,100; hæmoglobin, 65 per cent. Differential count: polymorphs, 79 per cent.; mononuclears, 1 per cent.; lymphocytes, 19 per cent.; basophils, 1 per cent. There were no changes in the shape of the red corpuscles. The blood-sugar was 0·18 per cent. The urine was clear, contained no sugar or albumin, and no renal casts. The blood-urea was 108 mg. per cent., and the urea-concentration test was normal.

Treatment.

The treatment of intermittent claudication in the past has been far from satisfactory, and has depended largely on the free use of vasodilator drugs and other remedies to act on the vasomotor spasm and relieve the ischæmia. Byrom Bramwell [8] remarked in 1907 that in cases which are not syphilitic "very little can, so far as we at present know, be done to cure the disease."

Recently diathermy has been tried fairly extensively and apparently with great success, because of its vasodilator effects on the small arteries and capillaries. According to Roeser,[10] diathermy is capable in some cases of checking the spread of the arterial block, and as the effects are rapid and there are no contra-indications to its use he advises its early application in all cases. This is important, as Lian and Descoust believe the good effects may be permanent.

General hygienic treatment should be carried out. Removal of septic teeth and other septic foci is essential as toxic absorption may be a factor in the production of the endarteritis which is probably always present. Abstinence from tobacco should be insisted upon, although it is difficult to believe that it had an important bearing in this case. Avoidance of exposure to cold and diminution of protein intake are recommended.

In this case all such treatment had been advised and followed since the condition was diagnosed in 1924, and regular treatment by potassium iodide, potassium nitrate, and nitrites had been carried out. Bier's congestive treatment seemed to give no relief. He was asked to drink 2 quarts of modified Ringer's solution daily, as recommended by Portis.[9] This solution is made by dissolving gr. 10 of potassium chloride, gr. 10 of calcium chloride, 6 drachms of sodium chloride, gr. 10 of sodium bicarbonate, and gr. 50 of dextrin in a gallon of distilled water. This treatment, however, was so distasteful to the patient that he did not persist for more than two weeks, although he has taken smaller quantities from time to time. After the amputation he was confined to bed, ensuring rest, but on several occasions he developed a sharp stinging pain in the left thigh with a large area of superficial blotchy redness on the outer side of the thigh; this yielded to local treatment by ichthyol ointment and warm applications.

The onset of the cerebral attacks decided us to try diathermy, especially as we were familiar with the good effects in cases of hypertension. Following the advice of Roeser,[10] Giraud,[11] Vaquez, and others, we gave exposures lasting 30 minutes, the maximum current used being 1000 milliampères. At first twice a week was considered sufficient, but later he was readmitted to the Royal Infirmary on Nov. 6th, and had this séance repeated daily for 20 days as recommended by Roeser and others. Lian and

Descoust emphasise that strong currents are not necessary and advise 1200–1500 milliampères.

If the plates are sufficiently large there should be a sensation of heat without burning or pain, and the blood thus warmed carries the superfluous heat to the rest of the body. There is probably, therefore, nothing to be gained by having one plaque over the seat of the arterial block. On one occasion we tried one plate over the left motor area, and this was the only occasion on which considerable headache followed the treatment. Improvement was noticed from the first, not only in the general well-being but also in the local effects. The writer's cramp speedily improved so that he could write with his usual facility in a short time, and his ability to walk was speedily restored. Pulsation in the femoral artery remained absent. Up to the present no further attacks have occurred, and the general health remains at a high level.

AN OUTBREAK OF SPOROTRICHOSIS AMONG SOUTH AFRICAN NATIVE MINERS:

BY ADRIANUS PIJPER, M.D. LEIDEN,
PATHOLOGIST TO THE PRETORIA HOSPITAL;
AND
B. DAVIDINE PULLINGER, M.B., B.S. LOND.

SPOROTRICHOSIS usually occurs in isolated forms. We met it as an outbreak comprising 14 persons. This lends interest to the cases, apart from the fact that this is the first time that sporotrichosis has been recorded in South Africa. We have formerly called attention to the relative frequency of nocardia infections in South Africa as compared with infections by fungi of larger calibre.[1] Our own fruitless efforts to find a case of sporotrichosis, extending over many years, had led us to believe that the disease was non-existent in the country.

The Lesions.

For a few months the mine medical officer had noticed that there was an increasing number of natives suffering from various kinds of sores which did not yield to ordinary treatment. Routine laboratory reports on material from these cases mentioned only the presence of staphylococci. One of us (B. D. P.), on a chance visit to the mine, made a tentative diagnosis of sporotrichosis, which was fully confirmed when material from one open sore was sent to our laboratory, and on a suitable medium produced a typical growth of fungus after five days. This culture was badly contaminated by cocci and fungi from the air. A special visit was then paid to the mine, and 14 suspected natives were examined. In five cases culture of the fungus was attempted, and was successful every time, twice by aspiration of pus through the unbroken skin, twice from the contents of an opened abscess, and once from an ulcer. The other cases did not possess suitable material for cultivation and were diagnosed as sporotrichosis because their symptoms were so very similar to those five, because they yielded rapidly to treatment with potassium iodide, and also because their blood serum gave satisfactory agglutination and complement-fixation tests. Wassermann reaction was positive in two cases only; one of these gave a positive culture, and the other one gave a particularly high agglutination reaction.

A "primary sore" was found in nearly all cases in the form of a localised ulceration on a finger or on the shin. Sometimes this ulceration showed slight signs of healing. Ten of the fourteen cases had all their lesions confined to one arm, sometimes as high up as the shoulder region. The other four had primary sores on the shin, in one case a very large dry granulating surface, and their lesions extended up the leg, sometimes reaching the buttock. These lesions, extending from the primary sores up the arms and legs, were easily palpable, taking the form of a lymphangitis with nodules in various places. Incision of the nodules, which felt like lymph glands or small abscesses, produced pus or serous fluid, but no healing followed this surgical treatment.

At the time of our examination two natives had been in hospital in connexion with the affection for five months. The other cases were of shorter duration, from a few weeks to four months. Apart from their lesions the patients were in good condition.

After administration of potassium iodide in the usual high doses all the natives returned to their work within two to three weeks.

Cultures and Serology.

All five cultures obtained proved identical. Their characteristics were briefly as follows:—

There was practically no growth in the incubator. This provided a method to ensure that cultures are pure, for contaminations which remain hidden at

FIG. 1.

Cultures of the fungus on Sabouraud's glucose-agar two months old.

room temperature will show at blood heat. It is surprising how often apparently pure cultures are found to contain staphylococci. This is important because we have found that the fewer staphylococci there are present, the longer it takes for the brown pigment of the fungus to appear. We therefore believe that the degree of staphylococcal contamination present in an individual strain of *Rhinocladium* (*Sporotrichum*) *beurmanni* is responsible for its falling into any one of the three sub-groups, α, β, and γ, as described by Gougerot,[2] and which are differentiated only by the rapidity with which pigmentation takes place. Our description applies to perfectly pure cultures.

Sabouraud glucose-agar (Fig. 1).—Growth starts after a few days, as a convoluted centre with marked areola, and it spreads until it reaches the glass. The areola becomes

[1] Jour. Trop. Med. and Hyg., June 15th, 1927.

[2] Gougerot: Kolle und Wassermann's Handbuch der Pathogenen Mikroorganismen, Bd. v., 1913.

very broad, up to 1 cm. Pigment is slow in coming; after a fortnight the growth is hardly tinged. After six weeks it is like very weak coffee, with milk; after two months it is typical café-au-lait, and still older cultures become chocolate-brown. The medium, however, darkens more quickly than the growth, and is dark brown after two months, becoming pitch black after that. Sections through cultures show that there is at least as much growth within the medium as on the surface. The surface growth is not coherent. The central parts always remain very convoluted and the highest crests rise 3 mm. over the surface. They are surrounded by a flat zone, and then follows the fringe of areola.

Milieu d'épreuve.—Growth very rich, convolutions often rising higher than on Sabouraud glucose-agar. Pigment develops sooner, both in culture and medium.

Potato and glycerin-potato.—After a fortnight quite white corrugated growth, covered with fine spicula, surrounded by areola. Medium and growth become brown after one month, and nearly black after two months.

FIG. 2.

Photograph of hanging-drop culture of fungus ten days old.

Beerwort-agar.—Aspect of growth as above, but pigmentation sets in much sooner, the crests turning quite black in a fortnight.

Carrot.—Very rich growth, very thick convolutions, keeping white for at least two weeks and then showing patches where dark black spicula arise. Carrot does not deepen much in colour.

Ordinary agar and milieu de conservation.—Poor growth, keeping flat, but convolutions visible, quickly turning brown.

Glycerin-agar.—Rich growth, keeping white for over a fortnight.

Blood-agar.—Good growth, darkening rapidly, no hæmolysis.

Dextrin-agar.—Rich growth, keeping just tinged for a long time. The medium shows no signs of clearing.

Litmus milk.—Keeps fluid, with dark brown skin on top, white sediment, and bluish colour.

Glucose-peptone-water.—Surface skins form which sink and form again. Colour, white to light brown. Medium remains slightly acid, but does not become pigmented.

Coagulated blood-serum.—Hardly any growth, and no liquefaction.

Starch-paste.—Growth keeps white for a fortnight, then liquefaction occurs.

Coagulated egg-white.—Good growth, without liquefaction. Growth keeps white for a fortnight.

Carbohydrates.—Good growth, but no change in the usual media containing glucose, lævulose, maltose, galactose, saccharose, lactose, mannite, dulcite, dextrin, raffinose, arabinose, adonite, inulin, sorbite. Usually white tufts at bottom, sometimes white skins on top. No pigmentation of medium.

Gelatin and *glucose-gelatin.*—Observations extending over two weeks. No liquefaction in either. Faint yellow tinge of growth on gelatin, no zona, convolutions present, trace of brown pigment diffusing into medium. Dark brown pigmentation on glucose-gelatin, brown pigment diffusing into medium.

Hanging-drop cultures (Fig. 2).—Branching threads, but dichotomy, thickness 1·3 to 2 micron. Conidia formed regularly along the threads, and also in bunches at ends of threads. No true conidiophores. The conidia measure 2 to 4 micron, and have a short pedicle, which remains attached to them. It also happens that the thread shows a protuberance where the spore is situated. After many weeks the threads are completely surrounded by the spores.

From this description it follows that the fungus isolated by us is *Sporotrichum*, or, to adopt Vuillemin's nomenclature, which we think is preferable,[3] *Rhinocladium beurmanni*. It differs only in one point, the non-liquefaction of glucose-gelatin. This may be due to our excluding all contaminations, especially of the staphylococcal kind (see above).

We are aware of the inherent fallacies of serological diagnoses in fungal infections, caused by their lack of specificity. We do not regard such tests as decisive, but as helpful. Positive agglutination reactions in serum dilutions varying from 1 : 80 to 1 : 320 were obtained with a suspension of spores in all cases where no attempt at cultivation had been made. Serums from various other patients gave negative results by this method. Complement-fixation tests were undertaken with an antigen consisting of the spores of a fungus which had been isolated from the nails of a patient with onychomycosis. This fungus, which has not been definitely classified yet, is at least closely related to the sporotrichons. Positive results were given by 7 out of 11 cases tested. Here also control sera gave negative results.

Animal Experiments.

These were undertaken to test the pathogenicity of the cultures. Three male white rats were injected intraperitoneally with a suspension of spores, and killed a fortnight later. They showed lesions in the abdominal wall at the site of injection, which had become hard and hyperæmic. Nodules were always found in the omentum in varying numbers. Liver and spleen were apparently normal, the chief lesions always being found in the scrotal sac. This was injected and showed nodules, and in one animal the testes were enlarged. Nodules were also found in the connective tissue round the testicles. On microscopic examination typically shaped spores were found in all these lesions, mixed with leucocytes, and surrounded by rings of fibrous connective tissue. Retro-cultures succeeded from all the lesions.

Discussion.

In South Africa sporotrichosis so far has been unknown. No pathologist lays claim ever to have isolated the fungus, although clinicians may have applied the term loosely to undiagnosed cases. It is strange that our own prolonged search should suddenly result in the discovery of an outbreak comprising 14 cases. The natives affected had nothing in common which differentiated them from the numerous other natives inhabiting the mine compound. They belonged to different tribes, had been in the service of the mine for periods from two to nine months, were engaged on different kinds of work in the mine, on different levels and in different shafts. They did not mix more with one another than with the other inhabitants of the mine. No simple clue was evident as to the origin of the infection. The seventy miles which separate the mine from the laboratory prevented further investigations.

We wish to thank Dr. A. J. Orenstein, superintendent of sanitation, Rand Mines, Ltd., and Dr. M. M. Pam, assistant medical officer, Modder East Mine, for giving us access to the clinical material.

[3] Brumpt: Précis de Parasitologie, 1922.

NEW POOR-LAW HOSPITAL AT STOKE-ON-TRENT.—The Stoke-on-Trent Board of Guardians recently unanimously approved a scheme for providing a new Poor-law hospital at a cost of £200,000. It will afford accommodation for 180 medical and surgical cases, with a central administrative block, an isolation block with 50 beds, a children's block with 44 beds, and a nurses' home with accommodation for 150 nurses. The special committee which recommended the scheme stated that, large as it is, it will be inadequate for the needs of the district, though it will do something to relieve existing difficulties. Dr. G. Gordon Lewis, the board's medical officer, stated that hospital accommodation in Stoke-on-Trent is quite inadequate, and added that it was "a disgrace that in a town with a population of 300,000 there is no provision for patients suffering from surgical tuberculosis."

Clinical and Laboratory Notes.

A CASE OF DIABETES WITH RENAL GLYCOSURIA.

BY C. VOIGT, M.D. LIVERP., D.T.M.,
SUDAN MEDICAL SERVICE; LATE HON. ASSISTANT PHYSICIAN, WIGAN ROYAL INFIRMARY.

AMONG cases of true diabetes it is, of course, not unusual to notice certain ones in which the sugar tends to appear in the urine at either a high or a low level of blood-sugar concentration. In view of the danger of an unrecognised low renal threshold to the successful control of diabetes by means of insulin, the following case may be of interest.

A railway worker, aged 38, said that in the last few weeks he had had to give up his employment on account of failing sight. He complained of (1) this failing sight, which he had noticed first about 12 weeks before; (2) thirst, which had troubled him for about six months; and (3) profound general weakness for the last three weeks. He was married and had one healthy child. His family history and previous history were irrelevant.

Upon admission to hospital he was found to have a blood glucose content of 626 mg. per 100 c.cm. There was marked ketonuria. Examination of the eyes revealed nothing of moment.

Insulin treatment was started, and while next day the fasting blood-sugar was found to be 110 mg. it was noted that there was still much sugar in the urine. In the sample passed half an hour after this blood sample was collected there was found to be 4 per cent., and in one passed one and a half hours after 3·6 per cent. of glucose. A confirmatory blood estimation was therefore made, and showed 125 mg. per 100 c.cm. A sample of urine half an hour later contained 3 per cent. of glucose. The following investigation was subsequently done.

Urine.—The 24 hours' sample never contained protein or casts. The diastatic index was 10; chlorides, 0·5 per cent. (total 10·95 g.). Urea nitrogen, 1·45 per cent. (total 30·74 g.).

Blood.—The serum Wassermann reaction was completely negative. The fasting chemistry was uric acid, 3 mg. per 100 c.cm.; urea nitrogen, 20 mg. per 100 c.cm.

Renal Efficiency.—(1) Urea concentration: second hour, 2·6 per cent., third hour, 2·9 per cent. (2) Phenolsulphonphthalein excretion: appearance time (intravenous injection), five minutes. First hour, total specimen, 45·5 per cent.; second hour, 30·7 per cent., making 76·2 per cent. in all. (3) The Mosenthal test gave the following:—

—	Test quantity.	Sp.G.	Glucose (per cent.).	Corrected Sp.G.
8 A.M.	3 oz.	1040	1·8	1035
10 ,, ...	5 ,,	1040	2·3	1030
Noon	5 ,,	1038	2·4	1030
2 P.M.	3 ,,	1042	1·6	1037
4 ,, ...	3 ,,	1040	8·3	1023
6 ,, ...	5 ,,	1042	10·0	1009
8 ,, ...	4·8 ,,	1043	1·0	1040
10 ,, ...	7 ,,	1040	8·3	1023
Next day, 8 A.M.	8 ,,	1040	12·5	1004

Total quantity, 73·8 oz. (2189·6 c.cm.). Chlorides, 500 mg. per 100 c.cm. (total 10·95 g.). Urea nitrogen, 1·45 per cent. (total 30·74 g.).

The two charts show the investigation of the renal threshold point for glucose. In the case of Chart A the use of artificial light was unavoidable, and this no doubt spoiled the sharpness of the result by making it difficult to detect slight reduction of Fehling's solution by the urine. The actual concentration at which, in this case, glucose begins to pass through the kidney seems to be about 80 or 90 mg. per 100 c.cm. of blood, and the patient will always have sugar in the urine, unless he is given a dose of insulin sufficient to bring his blood-sugar dangerously low. Exactly five minutes, in fact, after the sample of blood was taken (which in the investigation of Feb. 25th was found to contain only 0·063 per cent. of glucose), and while the urine was still glucose-free, this patient did begin to manifest the sympathetic over-action characteristic of hypoglycæmia.

A fractional gastric analysis revealed a tot absence of free hydrochloric acid, the total acidit reaching only 17·5 (at two and a quarter hours Bile appeared first at two and a quarter hours, an starch persisted up to two and three-quarter hour Radiographic examination of the stomach an

CHART A.

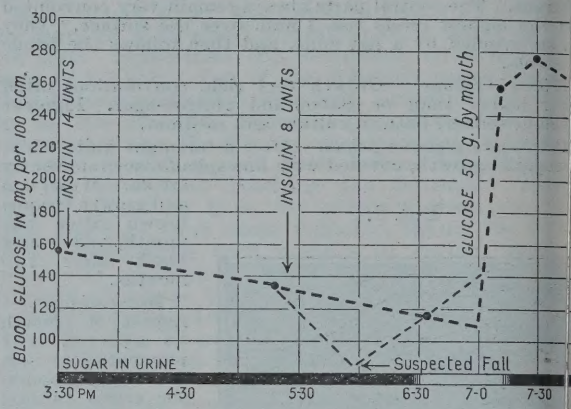

CHART B.

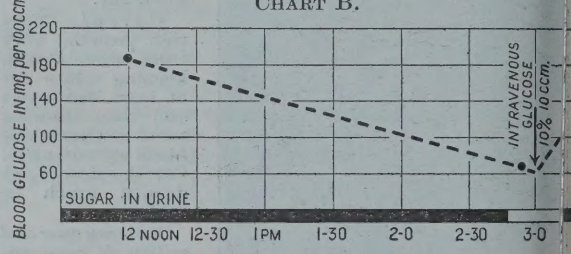


duodenum showed normal appearances, motili and emptying. A radiogram of the pituitary fo showed nothing of interest. The patient never l suffered from any dyspepsia or troublesome he aches. The systolic blood pressure was 138 m and the diastolic 90 mm.

Discussion.

It seems more than unsatisfactory to accept s very low renal thresholds for glucose—and m others raised to such levels as 210 mg. per 100 c.cm as inexplicable peculiarities, notwithstanding remarkable uniformity of the normal. Slight d in excretion of urea is certainly encountered in sc of cases where other tests acquit the kidney of inefficiency, as in the case under consideration, I have not observed such delay in uncomplica renal glycosuria. K. S. Hetzel [1] has an ingen explanation of the causation of hyperglycæmia acromegaly, and suggests that pituitary over-ac may, by direct action upon the kidney, raise threshold point. I could find no evidence of pituit insufficiency in my patient. Blood pressure read were not low, nor was the specific gravity, caref corrected for contained glucose, of the urinary sam throughout the day; nor had he any headac Admittedly, these points are not conclusive.

Since it seemed probable that the achlorhydria preceded the hyperglycæmia, the patient—after t weeks' treatment aiming at correction of ketos was put upon acid hydrochlor. dil. (ℳxx with w at meals), to see whether acid would have any e upon the glycosuria, perhaps by changing, how slightly, the hydrogen-ion concentration of the ser No change was noted. Possibly the lack of free hy chloric acid may have something to do with permeability of the kidney for even the most fe concentrated solutions of glucose—perhaps by turbing the balance of ferments in the alimen tract. T. I. Bennett and E. C. Dodds [2] have sh

[1] THE LANCET, 1926, i., 440. [2] Ibid., 1925, i., 429

hat glucose solutions are retained and diluted in the tomach. In this case there is evidence that carbo-ydrates are not hurried through a rapidly emptying omach; on the other hand, many processes in the ut will be modified by the want of the normal imulus of acid leaving the stomach. It may be structive to make gastric analyses in available cases renal glycosuria, and to investigate renal threshold oints of patients showing total achlorhydria.

A CASE OF HIRSCHSPRUNG'S DISEASE IN OLD AGE.

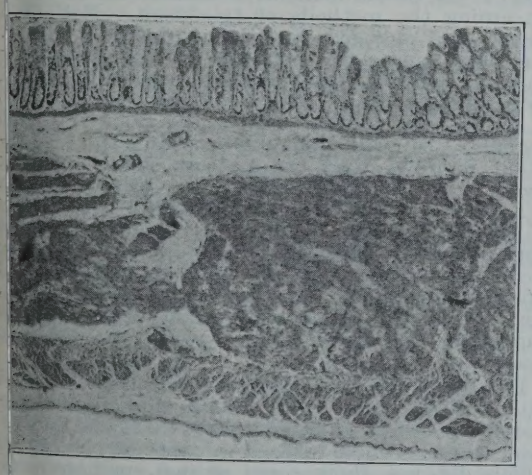
BY S. HAROLD COOKSON, M.D., B.SC. BIRM., M.R.C.P. LOND.,
MEDICAL REGISTRAR, MIDDLESEX HOSPITAL.

THE following case has interesting features.

In September, 1926, a man of 69 was admitted to the ddlesex Hospital with the major complaint of swelling the abdomen. He gave a history of good health, except constipation which had troubled him for some years; e years before admission he had a "very bad stoppage the bowels" for which the doctor thought an operation uld be necessary. Since then he had been taking large antities of purgatives. Four months before admission noticed that his abdomen was swelling, and this gradually reased, to be followed soon after by swelling of the legs, rtness of breath, and general weakness. His appetite s good, and as to habits he took alcohol moderately, glasses of beer per day, but smoked 1½ oz. of tobacco ly.

On examination he was found to be a very obese man; was not cyanosed but had to sit propped up in bed owing dyspnœa. The legs were slightly œdematous and the domen was very distended but not quite symmetrical. upper part of the abdomen and left flank were most minent. On percussion, dullness was only found in the flank; this did not shift with change in the patient's titude and there was no thrill. No definite tumour was

FIG. 1.



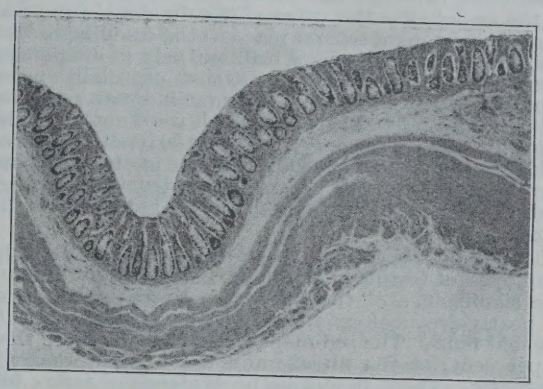
ction of descending colon from the case reported, showing thickening of muscular layer. (*Microphotographs from the Bland-Sutton Institute of Pathology.*)

able in the abdomen, and per rectum there was balloon-ut otherwise nothing abnormal. The heart was concealed ung and no apex-beat or cardiac dullness were to be out. The accessible arteries were only slightly ened and the blood pressure was 150/105. The physical in the lungs were those of emphysema and chronic chitis. The urine was normal and the central nervous m was intact. The blood Wassermann reaction was tive and the blood count and blood nitrogen figures within normal limits. After a few days in hospital lyspnœa and œdema of the legs increased, while three s after admission the abdominal girth was 53½ in.—is to say, 4½ in. greater than on admission. Constipation severe throughout the period of observation. After he had been in hospital a month the patient died suddenly while trying to defæcate after a turpentine enema.

At autopsy the large intestine was found greatly distended throughout; the diameter was maximal in the pelvic colon, where it was 6 inches. The walls were very thick, especially in the sigmoid and rectum; the latter was distended and occupied the greater part of the pelvic cavity. A large quantity of fluid and gas was contained in the colon. No evidence of organic obstruction was present in any part of the gut and the remainder of the alimentary canal was normal. The heart weighed 16 oz.; all its cavities were dilated; the muscle was fibrous; it showed brown atrophy, and the coronary arteries extensive atheroma. The cause of death was found in a large pulmonary embolus, the source of which was not traced.

The enormous hypertrophy of the musculature can be seen in Fig. 1, and by comparison with Fig. 2 it will be seen that its thickness is three to four times that of the normal. The mucosa is unaffected.

FIG. 2.



Section of normal descending colon to show th ckness of muscular layer.

The interest of this case lies in the age of the subject. The condition is commonest in childhood and under the age of 10 years its incidence is 1 in 10,000. It is very rare over 30, and as far as I have been able to discover no case has been recorded over 40.[1] Bartle [2] records the case of a patient with megacolon who survived till the age of 29, and then, like the present one, died suddenly while trying to defæcate. Of the many theories which are held on the cause of the disease, that suggested by A. F. Hurst seems the most satisfactory. He suggests that it is due to an achalasia, or failure to relax, of either the anal or pelvirectal sphincter. In the former case the dilatation involves the whole colon, while in the latter it occurs above the pelvirectal junction. The case reported falls in the first category, as the rectum showed considerable hypertrophy and dilatation. The defect, on this view, is analogous to achalasia of the cardia, which leads to œsophageal dilatation. As in the latter condition the treatment consists in periodic stretching of the sphincter concerned, supplemented by enemata, abdominal massage, and exercises. Pituitrin injections and a low carbohydrate diet are also recommended.[2]

At what age, in the present case, the neuromuscular incoördination, which seems to be the likely cause, developed is a matter for speculation. All that can be definitely stated is that constipation was severe for the last five years of the patient's life; on the other hand, abdominal swelling had only been noticed for four months. The patient was an obese man, however, and it is not unreasonable to suppose that the colon had been dilating and producing a slow abdominal enlargement for years without attracting his attention. Also the degree of hypertrophy present in the colon muscle is not developed in a few months.

I am indebted to Dr. R. A. Young for permission to publish this case.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

AT a meeting of this Society, held on Oct. 24th, Mr. HERBERT W. CARSON, the President, in the chair, a paper was read by Dr. VINCENT LYON (Philadelphia) on the development of the

Duodenal Tube and its Practical Value

in diagnosis and treatment. Dr. Lyon began by paying tribute to the work done on the subject in the past by British and American workers. As a diagnostic agent, he said, the duodenal tube was of less service in some regions than were other methods, but in all it afforded evidence not procurable by other means. In the œsophagus the value of the duodenal tube was limited and took a second place to the œsophagoscope and bougie; but it was of brilliant help in diagnosing stomach and duodenal conditions, especially when supplemented by X rays. It might indicate gastritis, catarrh, and reflex disorders which were not recognisable by the rays only. Particularly it rendered evident early primary alterations in the mucous membrane—i.e., long before gross structural change had developed to an extent to be recognisable by X rays.

Dr. Lyon proceeded to describe the method he employed of testing the 12-hour fasting residuum and the significance of the findings. Normally this was of pearly-grey colour and of the consistency of thin mucoid fluid. The sediment should not be more than 5 per cent. of the filtrate and the odour pleasantly aromatic. There should be no evidence of reflux bile colouring unless there was a pronounced gag reflex in swallowing the tube. Bile in the fasting stomach day after day was often the cause of morning nausea and a bitter taste at breakfast and anorexia. There should be no gross bleeding, and when such was present it suggested the presence of cancer, ulcer, papilloma, or syphilis.

Before, however, drawing conclusions from the presence of occult blood a careful examination should be made of mouth, gums, and pharyngeal mucous membrane. The fasting acidity was variable in degree, and it was doubtful whether there was a dependable normal to work upon. Many factors might influence it, such as sleeplessness, much alcohol taken the night before, worry, &c. The microscopy of the fasting residuum was also of much importance, especially was its analysis on a quantitative scale. If food abnormally retained contained meat fibre, starch cells, or fat globules, this showed either motor delay or unusually deep rugæ.

In the duodenal zone the duodenal tube possessed great diagnostic value in the majority of cases; he based this statement on many thousands of cases. It was a relatively easy matter for a soft rubber tube of small calibre to be carried through the pylorus into the duodenum, and he found no difficulty in intubating the duodenum in 20 minutes in a normal case; longer must be taken for a pathological one. Normally the pylorus rhythmically opened and closed four or five times each minute, and when the end of the tube was impinging on the pylorus and with the patient swallowing each minute, it would soon be able to enter the duodenum, and it then lay in the second portion of the duodenum in close relation to the common bile and pancreatic duct. As much duodenal contents as possible should be secured and its colour and characteristics noted, its mucoid content and degree of flocculation.

Practically all the text-books stated that the mucous membrane of the small intestine was lined only by columnar epithelium, but he and his colleagues had been impressed by the fact that the commonest cellular exfoliation from the duodenum was oval or cuboidal, not columnar. With the tube in the duodenum the occurrence of microscopical bloo or occult blood was highly suggestive of duoden ulcer or carcinoma of the head of the pancreas. H and his colleagues had made several classes of duoden condition, such as the simple catarrhal, the exfoliativ the ulcerative, the infective. It had been found tha in the sick cat and dog the motor power of the gal bladder was distinctly diminished.

A differentiation should be made between cyst and common duct catarrh, and there ought to be careful microscopical examination made of the bi fractions secured. He considered that the mo important finding was an oleaginous material, whic melted out in globules and was found in minute lake Chemically it was not a true fat, but a fat ester cholesterol. In acute, subacute, and chronic chol cystitis there was an increase in the bile-staine material. In calculus cholecystitis the bile was oft loaded with crystals—i.e., cholesterol, calcium, an bilirubin. Some gravel stones had been recovered biliary drainage.

Over a large number of cases the duodenal tul diagnosis was found to be correct in 88 per cen Only positive findings were of diagnostic value. some cases the mucous membrane had been complete denuded, and in them the diagnosis of non-calcul cholecystitis must be made by physical and X r examinations and by X ray examinations, as well by a chemical study of the blood. When bett physiological and chemical methods had been devis for the quantitative estimation of normal a pathological findings and evidence in regard to t bile, a greatly renewed impetus would have tak place, and many at present baffling problems wou probably be elucidated.

In the medical variety and that due to parasit also that due to toxæmia associated with hepati and cirrhosis of the liver, the use of the duodenal tu was of great value. It was also of great help treating persistent hiccough. Also its employment biliary tract drainage and in duodenal lavage v worthy of a trial. In regard to the treatment of pep ulcer, in the States there was considerable discont concerning the methods of treatment. Methods surgery had changed, but the morbidity continu Ten years must elapse before it could be known h many patients who had undergone treatment develo pernicious anæmia or other complications, as a res of radical technique. It was the poor who m frequently suffered from peptic ulcer, and the c dition required that the patient should have weeks of total disability and a year of partial ret to normal activity. An investigation of the ætiol of the ulcer, the mechanical or chemical agency work, any ulcer diathesis, syphilis, &c., would ena the disease rather than the ulcer to be treated. I infective, foci should be searched for and dealt w such as in the antra and dental areas. It important to avoid any routine rule-of-thu treatment.

Dr. Lyon and his colleagues had been impre with the frequency with which they found in abdominal lesions; indeed it was rare to find duod ulcer alone. There were few cases of cholecys which did not show some erosion, perhaps ac ulceration, in the duodenal aspect. During effort deal with ulcer one might be aggravating a ch cystitis. Speaking generally, Dr. Lyon said the met was found to be sound, and the results achieved f the use of the tube were superior to any they previously obtained. No suitable cases for treatment had, so far, required operation. Eff were made to get the patient to understand the na of his disease, and the tendency to relapse; it w necessary he should realise that a careful life he forth was required of him as in the case of a phthi patient.

Discussion.

The PRESIDENT narrated a case which had rec been under his care, that of a man aged 62, who admitted six months ago with an ulcer of the l

urvature, with the typical symptoms—pain, vomiting, nd loss of weight. There was a 12 years' history of rouble, and during the four months before coming to ospital his symptoms had been continuous. X ray xamination showed two ulcers, both on the lesser urvature. One of them had a crater towards the ylorus, the other being a small bud higher up. This, e thought, made it impossible to treat the case by adical measures. He therefore adopted feeding hrough the duodenal tube. He was fed through that, ith short interruptions, for ten weeks, and the ccessive skiagrams (shown on the screen) demonrated the gradual disappearance of the ulcer. From ie time of the institution of that treatment the man ost all his symptoms, and for four months after he ent out there had been no return of them; he mained in perfect health and was putting on weight.

Dr. ERNEST YOUNG said that for the last four and a alf years he had been using the duodenal tube for arious disorders of the gastro-intestinal tract, his 3 cases embracing gastric and duodenal ulcers, onic stomach, chronic colitis, nervous vomiting, and pe-worm trouble. The most important service of ie tube was in gastric and duodenal ulcer; in these nditions it had yielded him better results than had ny other form of medical treatment. He demonrated the apparatus he used. The tube was retained the patient for a period of one to three weeks. eding took place through the tube for 18 days, ght liquid feeds being given through it daily at o-hour intervals, which enabled adequate nourishent to be kept up. The object was to secure rest to e ulcerated site. The food could be varied, and if cessary an aperient could be given in the same way, a little morphia for sleeplessness. On the fourteenth y the patient was allowed out in the armchair for short time, and when the tube was withdrawn dinary solid food was at once resumed. Vegetable d other fibrous food should be first passed through sieve when using the tube, to avoid its blockage. e gave details of cases, and said that if there was a apse of the ulcerative condition after the medical atment, he refused to institute a second course, mmending, instead, operation.

Mr. A. J. WALTON said an important matter was e diagnosis of the presence of gall-stones. His perience was that the cholesterol found had always en deposited from a diseased gall-bladder, not by process of crystallisation. He had therefore been erested to hear Dr. Lyon say that crystals had en recovered by the tube in gall-stones. If that were epted, it would be a strong argument for medical her than surgical treatment. As to the surgical atment of ulcers, he thought every surgeon would ree that the surgical treatment of gastric and odenal ulcers must be only a temporary phase; to k out such a lesion was but a gross form of treatnt. He agreed that the results of it had been isfactory, but thought it was destined at a future e to be abandoned. It was difficult to determine at was the value of medical treatment, because it s necessary to ascertain what were the permanent ults of treatment. All persons could be relieved of ir ulcer symptoms by medical treatment, but how g would they last in the conditions they had to urn to? Very few could alter their occupations l conditions of life; therefore efforts must be made so alter the patient's physiological conditions that tendency to ulcération would be overcome. He ught that some of the forms of treatment now pted were too advanced, and he had taken a stand inst the ruthless performance of partial gastrectomy small ulcers of the lesser curvature. He favoured re local procedures. Only by following up the es could one determine accurately the end-results. instituted such a department at the London spital in 1919, and he gave the general statistics ich had resulted.

Dr. T. IZOD BENNETT was able to confirm all that Lyon said, from the diagnostic point of view, as the value of the duodenal tube, and particularly in case of gastric carcinoma. He had not had much experience of the tube for diagnosing lesions below the pylorus. Several cases had occurred in his own practice in which the tube enabled a diagnosis to be made of a pancreatic as opposed to a biliary lesion. The pylorus he looked upon as a valuable dam, separating the upper from the lower portions of the intestinal tract, and he always felt diffidence about penetrating that dam.

Dr. J. A. RYLE emphasised the importance of ascertaining as much as possible about normal conditions before drawing conclusions concerning the abnormal. Also it was very important to get the previous story of the particular ulcer in question, and the various treatments to which it had already been subjected. Diagnosis at a much earlier stage, which the profession as a whole should give more attention to, would render surgery far less necessary. Rarely did one see a case of gastric or duodenal ulcer with a history of less than six months.

Dr. STANLEY WYARD agreed with all that had been said in the discussion as to the value of medical treatment in the kind of cases under consideration, but he had been impressed by the risk of perforation or hæmorrhage during the progress of the medical treatment. For duodenal and gastric ulcer in the neighbourhood of the pylorus, therefore, he thought surgery offered the greater safety to the patient.

Dr. LYON replied in detail on the points raised.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ELECTRO-THERAPEUTICS.

THE opening meeting of this Section was held on Oct. 21st, when Sir HENRY GAUVAIN gave an address on

Electro-therapeutics and the Future of Medicine.

He took his election to the presidency of the Section, he said, as a sign that members regarded the science of electrotherapy as embracing the full range of electromagnetic vibrations as a means of alleviating human suffering. Recent progress and achievement in this branch of scientific medicine compared favourably with that of any other. The developments which could be reasonably anticipated in the immediate and remote future made an irresistible appeal to the imagination. Few dreamers 100 years ago could have conceived that by submitting a subject to forces impalpable and invisible the inner structures of tissues and disease processes could be shown, rickety bones restored to normal, one person made bald, another enabled to grow luxurious locks. Imagination based on ascertained facts pointed the way to new discoveries. Where were the new forces leading us? Three practitioners of the specialty would indicate the advances which had recently taken place, dealing with the practical application of radiological methods to the diagnosis and treatment of two of the most serious afflictions of mankind—tuberculosis and cancer. The President thought it was imperative that all medical practitioners should have a perfect and thorough, if elementary, knowledge of the principles and practice of electrotherapy. He doubted whether its importance and potentialities were adequately recognised by the profession as a whole. The time had surely now come when systematic instruction in these methods should be given to all medical students. For this to be practicable, the status and influence of radiologists on hospital staffs should be further raised; they should rank equal to the physicians and surgeons, with their own wards, beds, and teaching facilities. The advance of this special branch in hospitals had been unduly delayed, to the detriment of the patient.

X Rays in Diagnosis and Treatment.

Dr. DUNHAM (Cincinnati, U.S.A.), a corresponding member, first paid a tribute to the good work done by the President in the field of phototherapy and electro-

therapeutics. The speaker's own work in this domain began in 1890 at St. George's Hospital, London, and he arrived at the view that if the radiologist wished to help the clinician he must translate X ray densities into terms of pathology. It was his experience that in order to do this with any accuracy, stereoscopic views must be taken. To understand the processes at work in diseased lungs, both a macroscopic and microscopic study must be made. Stereoscopy enabled the observer to detect the exact site of varying densities of shadow, and periodic skiagrams gave a clear idea of the progress of a given case. He illustrated this in a series of slides of several cases. Tuberculosis of the lung was clearly a disease of successive infections; one got well but another broke down. It was the business of the radiologist to keep a careful watch on these areas. In America there was so much anxiety to make the earliest possible diagnosis from the X ray plate that all did not realise the value of the rays as a guide to the continued care and treatment of the case. The worst thing the radiologist could do was to give to the clinician a haphazard guess. It was difficult to arrive at a diagnosis of miliary tuberculosis without a careful consideration of the history of the case. The clinician, on his part, should take the physical signs and translate them back to pathology, thus establishing common ground.

Dr. J. GRAVESEN (Denmark), who also was elected a corresponding member, gave an epidiascopic demonstration entitled

The Qualitative Radiological Diagnosis of Pulmonary Tuberculosis.

In recent years, he said, some very good results had been achieved in his clinic in cases of pulmonary tuberculosis. During the last 20 years, collapse therapy had developed to a very considerable extent; it was originally suggested in the form of artificial pneumothorax, and recently a chemo-specific remedy, sanocrysin, had greatly strengthened the means available for combating the disease. The two methods combined were responsible for a great reduction in the number of cases in which failure had to be confessed, and at the same time had considerably shortened the period of treatment in many instances. Sanocrysin was indicated in cases in which certain anatomical conditions were present—e.g., when the affection was of a fresh, exudative nature. Benefit could not be expected from it in all kinds of cases, and the failure to realise this was responsible for the diverse opinions which had been expressed about the remedy. In late cases, especially those showing cavitation and in which fibrosis had already occurred, the results from the use of sanocrysin were practically nil. Collapse therapy was applicable to the cases in which sanocrysin did not act. These facts rendered all the more necessary the careful use of every means towards a correct diagnosis of the actual type of case being dealt with. The diagnosis should not only include the degree of extension of the disease, it should give an impression of how the lungs looked, from the anatomical standpoint. X rays, stereoscopically used, gave the best help towards a qualitative diagnosis of this disease, and hence were the best guide to the right treatment in a given case. Dr. Gravesen showed an instructive series of slides, taken at different dates, to demonstrate successful results achieved by the two kinds of treatment in the types of case for which they were respectively suitable.

Cancer of the Breast.

Prof. HANS ISELIN (Bâle) contributed a paper on the treatment of cancer of the breast by X rays after operation. He said his efforts in this connexion were carried on from 1906 to 1913, and when Mr. Sampson Handley said he had obtained no very successful results in the treatment of cancer of the breast by X rays, the speaker had been for five years treating in this way inoperable primary tumours and inoperable recurrent growths. In the application of the rays to small operable recurrences and gland metastases he had already been obtaining go results. The most dangerous form of cancer, considered, was scirrhus, and the least dangerous w medullary carcinoma. The best results obtained fr operation were in a series of 62 cases, in which had 48 per cent. of cures. Obviously surgeons h not been satisfied with the cures they had be securing, seeing that they were anxious to ins that an arbitrary period of three years' freed from the disease should entitle them to make cla to a lasting cure. Only slowly did X ray treatme find a place in surgical practice. He had hims observed fatal recurrence of malignant disease af eight years, even after 16 years immunity. Ev with the help of X rays a lasting cure of cancer of t breast was relatively rare. Heidenhain had sho that in order to remove not only the tumour b also the cancerous lymph tracts and glands, a radi operation was necessary. The spread of the can in the direction of the normal lymph stream was o the beginning of the trouble. The writer of the pa did not remove the pectoral muscles in relativ hopeful cases, but confined his attention to extens removal of the fascia. Cancer of the breast was, declared, very suitable for X ray treatment. As growth might spread in all directions, mere irradiat of the affected breast was not sufficient, it must supplemented by prophylactic treatment of the wh area. But he had never been a believer in intens treatment by the rays, and did not employ in cases under consideration what was known as carcinoma dose. He had applied X rays in putrefy cancer, as a cautery, without using a filter. whole of the cancerous area, so far as it could be se was removed by operation and the walls afterwa exposed to X rays; the wound was covered w skin flaps. The patient died shortly afterwa however, from cellulitis of the floor of the mou Autopsy showed there was no cancer remaining, the irradiation had acted badly on the patient unduly lowering her vitality. As soon as a pati was somewhat rested after the operation, X applications were commenced, even as early as first week. After the exposures ceased the pat was still kept under observation. The general c dition should be carefully considered before decid on irradiation. The use of the aluminium filter no longer regarded as old-fashioned, and was ag coming into prominence. In conclusion, Prof. Is said irradiation had improved the bad prognosi cancer of the breast by 50 per cent.

On the motion of Sir PERCIVAL HARTLEY, secon by Dr. CLIVE RIVIERE, a cordial vote of thanks accorded to the speakers.

LONDON CLINICAL SOCIETY.

EXHIBITION OF CASES AND SPECIMENS.

A CLINICAL meeting of this Society took plac Oct. 20th at the London Temperance Hosp when the chair was occupied by Mr. HERE PATERSON, the President.

A Case of Aneurysm.

Dr. P. K. BYRNE showed a man, aged 63, complained that for some time he had been sho breath on moderate exertion. He was somev stout, and had at first attributed his breathless to that fact. Two months ago a severe pain on left side woke him up, and he feared he was a to die. There had not been a repetition of severe pain. However, his panel doctor, on consulted, ordered him to take a holiday, an that appeared not to have benefited him he can the hospital. He was found to have marked puls on the left side of the chest, and a definite tra tug. There was much difference of opinion a the staff as to the condition of the vocal cords. pulse on the left side was less than on the Wassermann was positive. Since iodide of potas had been commenced there was much improve

Dr. H. H. SANGUINETTI raised the question whether the more modern and thorough methods of treating syphilis had modified for the better the prognosis of aneurysm, or was it still found that cases of the kind inevitably came to a tragic termination?

Dr. DOROTHY LOGAN related a case she saw some time ago in which a gumma in front of the aorta had eroded through the sternum and weakened the aortic wall, so producing what was practically an aneurysm. Active treatment resulted in a very satisfactory clearing up of the condition, and the threatened complete break-through was thus averted.

Dr. E. G. FRENCH said he thought there was no doubt that the modern treatment of syphilis did improve cases of aneurysm. He treated a number in the Army, with beneficial results, and he had had several cases in private of which he could say the same. A particular case was that of an inspector of police who had a marked aneurysm. After three courses of antisyphilitic treatment he got remarkably well, and was able to go up and down stairs. Modern treatment should always be given in cardiovascular cases in moderate doses. Many seemed afraid to give this treatment, but he was sure it was safe.

The PRESIDENT remarked that when once the artery had sustained a certain degree of damage no amount of treatment would make a success of the case, as destroyed tissue could not be replaced, and dilatation would continue.

Dr. MATHER CORDINER showed a number of skiagrams bearing on the subject of the

Radiological Diagnosis of Chronic Appendicitis.

He said he had had a number of cases of appendicitis in which the clinical signs and symptoms did not point to the appendix as the seat of the trouble. In four instances the symptoms seemed to point clearly to gall-stones, or cholecystitis; radiograms, however, clearly indicated that the appendix was diseased. In those cases the gall-bladder seemed to have been secondarily infected from the appendix, so setting up a catarrhal cholecystitis. In three cases the appendix was found in the region of the gall-bladder, and there was an undescended cæcum. One skiagram showed an undescended cæcum, and an appendix on the left side of the spinal column. Another showed calcareous infiltration of ileocolic glands. He had found this condition in 15 per cent. of his cases of appendicitis. In this condition the seat of tenderness was not at McBurney's spot. In some cases of appendicitis the stomach was similar to that seen in association with duodenal ulcer; it showed hyperperistalsis.

Mr. H. P. WINSBURY WHITE asked what symptoms Dr. Cordiner found to be associated with calcareous ileocæcal glands. Patients complained of pains which were very suggestive of colic, and it was difficult to know whether the patient had intestinal or renal colic. The clinical findings associated with such a pathological condition of glands were very obscure.

Dr. A. J. CLARKE asked as to the history usually given by patients with this kind of appendicitis. Had they had dyspeptic symptoms for some time previously, and developed appendicitis on those?

The PRESIDENT said he had found that children who had recurrent attacks of vomiting without pain were very apt, in later life, to develop either appendicitis or gall-stones; the latter was often an effect secondary to the diseased appendix. He did not agree with the exhibitor as to the kind of stomach associated with chronic appendicitis: what he had found in these cases was a dilated badly contracting stomach. Of course the abdomen should not be opened unless the X ray picture confirmed the opinion already formed.

Dr. CORDINER, in reply, said that in most of the cases there was a sudden attack of uncontrollable vomiting. All the symptoms cleared up after the appendix was removed. The position of the appendix varied in different persons, and radiography was necessary to a correct location.

Dr. FRENCH showed two cases of

Chancre of the Lip.

The first case was that of a woman, who was kissed by a man, and three weeks afterwards a sore appeared on her lower lip. When she came to hospital the submental glands were marked, and the chancre had a glazed appearance. Mr. Sanguinetti confirmed the diagnosis. She was given ten weekly injections of 0·45 g. of neokharsivan, increased to 0·6 g. and a gramme of mercury cream. The chancre cleared up in three weeks, and the Wassermann had become negative. The second young woman had a chancre of the upper lip, and she said she had been to a dance and her partner bit her upper lip. On that site she developed a chancre. She had had only a week of treatment, yet there was but little left of the chancre at the time the case was exhibited, but there was typical ulceration of the fauces. She was being kept on 0·45 g. injections and mercury. He had found that extragenital chancres were accompanied by more severe systemic disturbance than genital ones: possibly the inguinal glands had more power to protect the system than had the submental. A third patient, a married woman, had, when seen, already developed a secondary papular rash.

If cases of syphilis were seen early, perhaps one course, such as that he outlined, would cure the patient, but a Wassermann test should be carried out every two months. If it continued to be negative for a year, the patient could be declared safe in the matter of infection, and could, of course, be allowed to marry. When secondaries were present, however, the patient had severe systemic disease, and more prolonged treatment would be required than in such cases as the first two. In the case of women, should they become pregnant after having had syphilis, even though the Wassermann had persistently remained negative, it was wise to give courses of "606" until term, as otherwise they had proved capable of producing a syphilitic infant. It was not easy to say why this was so.

Case of Swelling of the Breast.

Mr. A. D. JONES showed, for the President, a woman, aged 69, who complained of a swelling in the left breast, which she said she had noticed three weeks ago for the first time. It had been discharging for a week, she was losing weight, and there was some pain in the swelling. The breast was definitely cystic, but deeper an indurated mass could be felt. Operation was proposed, but had been deferred because she had extensive dermatitis. No glands could be felt in the axilla. It had been suggested that the case might be one of Brodie's sero-cystic tumour, but Mr. Jones inclined to the view that the condition was malignant—a carcinoma which was breaking down and discharging—though the absence of palpable glands was somewhat against this. He did not doubt that the swelling had been present longer than the woman stated. The right breast was normal. A dermatologist had given his opinion that the lesion was not a gumma.

Mr. SANGUINETTI suggested that syphilis of the breast might be more common than was usually supposed. He did not regard the present case as one of carcinoma.

The PRESIDENT said that the only specimen of gumma of the breast in the museum of the Temperance Hospital had been regarded for some time as sarcoma. It was a very hard growth, it had grown rapidly, and there were no enlarged glands. Brodie's sero-cystic disease was, of course, malignant. It was unusual to find sarcoma of the size in this woman with no glands, and breaking down as this was. He could not feel positive it was not gumma.

Hydronephrosis in a Child.

Mr. WINSBURY WHITE showed a specimen of the left kidney with the whole of the ureter attached, which was removed from a boy aged 2½ years. The ureter was dilated and there was some dilatation of the kidney; a stricture was seen at the lower end of

the ureter, and another stricture at the top. The mother brought the child to the hospital because on several occasions there was blood in the urine. At first he had been unable to ascertain by the cystoscope which kidney the blood was coming from, but ultimately it was seen to arise from the left ureter. The passage of a ureteric catheter under the guidance of X rays showed that the condition was a megalo-ureter with hydronephrosis. A pyelogram showed that the fellow kidney was normal, and he then removed the offending kidney; it was impossible to do a plastic operation. The child did very well, and it had now lost its pyuria.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.

ON Oct. 11th Dr. JOHN BOYD ORR read a paper on the

Influence of Diet on the Physiology of the Stomach.

He pointed out that in much of the earlier work there had been a tendency to limit attention to phenomena occurring in the stomach as if it were a semi-independent organ. The work of the past few years, however, had emphasised the close physiological relationship and interdependence between the stomach and the other parts of the alimentary system. A derangement of function originating in any part of the canal was likely to disturb the normal gastric activities, and many clinical symptoms located in, or at least referred to the stomach, had their origin elsewhere.

Discussing the function of sensation, Dr. Orr distinguished between hunger and appetite. The former could be correlated with the contractions of the gastric muscle, but the latter depended not only upon the tonus of the muscle, but also upon stimuli received from sight, smell, taste, and memory. Instances were given of perverted appetites in animals, and it was shown that these tended to occur on deficiency diets, and that often the abnormal substance craved for was rich in the substances in which the diet was deficient. Hunger, it was suggested, might indicate a demand for food in quantity, whereas appetite was to some extent an indication for food with certain qualities. Most modern work indicated that perverted secretion, or excess or deficiency of gastric juice, was of less importance in the ætiology of disease than had been formerly supposed. He regarded movement as the function which played the most important part in the maintenance of health and the causation of disease. Recent investigations had shown that the conception of the acid-alkali control of the pylorus was untenable. The movements of the stomach, including those of the pylorus, were of the same nature as those of the rest of the intestine, following the law enunciated by Bayliss and Starling. In health the pylorus was seldom if ever completely occluded. Whilst the general movement of the food was onward from the stomach to the intestine, there was a normal tidal flow between the duodenum and the stomach, and it was this tidal flow which regulated acidity in the latter organ. The chief factors which normally influenced movement were diet and the emotions. Dr. Orr quoted experiments showing that the composition of the diet had both an immediate and a remote effect upon movement, the remote effect being produced by an alteration in the circulating fluids of the body. One of the most interesting results of experiments with deficient diets was not the gross disturbances in the body which followed their use, but the disturbance of intestinal movement, which led to lesions such as inflammation and ulceration, especially in the pyloric and cæcal regions. Dr. Orr believed that emotions such as fear, anxiety, and anger, which stimulated the sympathetic, causing inhibition of movement and contraction of sphincters in the intestine, were an important factor in producing stasis in the lower part of the tract, and that this stasis was often the beginning of permanent lesions.

Reviews and Notices of Books.

RECENT ADVANCES IN OPHTHALMOLOGY.

By W. STEWART DUKE-ELDER, M.D., F.R.C.S. Assistant Ophthalmic Surgeon, St. George's Hospital. London: J. and A. Churchill. 192[illegible]. Pp. 343. 12*s.* 6*d.*

THIS book will be of great service to those wh[illegible] already have a competent knowledge of ophthalm[illegible] science, but have not had time of late years to kee[illegible] themselves up with the latest investigations an[illegible] their applications to practice. Those parts of th[illegible] subject, such as refraction, which may be considere[illegible] settled, are not touched on at all, and the boo[illegible] conforms strictly to its title. First we have a discu[illegible] sion on the nature of light according to the mo[illegible] recent theories, its transmission through the ey[illegible] its absorption by the different media, and its biologic[illegible] action upon them. As to the action of light upon th[illegible] retina itself, and its transformation into nervo[illegible] impulses, there is as yet very little real knowled[illegible] though theories are rife. The author thinks th[illegible] until a more adequate foundation of experiment[illegible] evidence is available, these theories are of litt[illegible] scientific value. There is, however, general agreeme[illegible] that the chemical action of light on the visual purp[illegible] is an essential to the phenomenon of vision and[illegible] proponderance of agreement as to the existence [illegible] the retina of a double mechanism one called "ph[illegible] topic" for the light-adapted eye, depending upon t[illegible] cones, the other "scotopic" for the dark-adapt[illegible] eye, depending upon the rods. The former is co[illegible] cerned with what is termed visual acuity, the latter[illegible] characterised by its sensitiveness to stimuli of ve[illegible] low intensity.

The second chapter deals with the theories [illegible] accommodation. The classical one of Helmho[illegible] appears to hold its own, but requires modificatio[illegible], the most important being that of Fincham, wh[illegible] points out the prominence of the part played by t[illegible] lens-capsule. If his facts are confirmed, the argume[illegible] for the rival theory of Tscherning lose their for[illegible]. The more recent theory of Thomson Henderson [illegible] the part played by the sympathetic nerve is sever[illegible] dealt with. The cause and differentiation of phys[illegible]-logical and pathological halos are also explained.

The next chapter deals with the embryology [illegible] the human eye, and the congenital defects that c[illegible] only be understood by reference to it. In t[illegible] connexion reference is made to a forthcoming w[illegible] on the subject by Miss Ida C. Mann. Chapter [illegible] deals with new methods of diagnosis. The slit-la[illegible] is undoubtedly the most important of these, but t[illegible] must be considered as an adjunct to the older meth[illegible] of histology and clinical study, not as displac[illegible] them. The chief new knowledge which it has int[illegible]-duced is as to the structure of the normal and disea[illegible] lens. Koeppe's proposal to extend the principle [illegible] means of the contact glass to a microscopical exami[illegible]-tion of the living fundus is not considered of m[illegible] practical value. The methods and advantages [illegible] examination of the fundus with a red-free light [illegible] given, and an instrument called the gonioscope [illegible] described which renders possible the examinat[illegible] of the angle of the anterior chamber under a mag[illegible]-fication of 32 diameters.

The chapter on the general physiology of the [illegible] deals with intraocular pressure and the nature of [illegible] intraocular fluids, abstruse subjects on which th[illegible] is still much discussion to which the author [illegible] himself made important contributions. The subj[illegible] dealt with under the heading, Diseases of the E[illegible], include high blood pressure and arteriosclero[illegible], glaucoma, cataract, and sympathetic disease. A practical point in the diagnosis of glaucoma is a d[illegible] in the development of dark adaptation and a dul[illegible] to the sensitiveness for dim light, while the sens[illegible] light difference remains unaffected. As to catar[illegible], the slit-lamp has thrown much light on the var[illegible] forms which it assumes, but there is little adva[illegible]

in the direction of explaining its ultimate causes or its prevention by medical treatment. Permanent opacities are due to coagulation of the proteins of the lens, but what causes this coagulation has yet to be discovered. When once the process has occurred nothing except removal by operation can restore transparency. Under the heading Sympathetic Ophthalmitis the newer methods of diagnosis, or assistance to diagnosis, are mentioned—Harrison Butler's slit-lamp test and the differential blood count; also some space is devoted to the anaphylactic theory of A. C. Woods. Coming to therapeutics, considerable interest attaches to the methods and results of ultra-violet phototherapy, on which the author is himself an expert, and which has found its chief use in obstinate cases of phlyctenular disease. The last chapter is concerned with the neurology of the visual paths and centres, the oculo-motor system, the trigeminal nerve, the pathological lesions in herpes, and finishes with an abstract of Sir J. H. Parsons's "Introduction to the Theory of Perception."

The work, though of modest proportions, is no light reading even for the trained ophthalmic surgeon. He will find much in it to stimulate thought, and the bibliographies which are appended to each chapter will help in further study.

SYMPTOMATOLOGY.

Klinische Symptomatologie Innerer Krankheiten. Krankheitssymptome (mit Ausnahme der Schmerzempfindungen). Second edition. By Prof. Dr. NORBERT ORTNER, University of Vienna. Berlin: Urban and Schwarzenberg. Vol. II. Pp. 330. M.15.

THIS is the second of three volumes, the first being divided into two parts dealing with abdominal pain and body pain respectively, while the third volume describes general clinical symptoms and differential diagnosis. The second volume deals with well-known symptoms common to many diseases, such as cachexia, loss of appetite, coma, diarrhœa, cough, dyspnœa, jaundice, dyspepsia, tachycardia. Only symptoms not associated with pain are considered. Each symptom is described in a separate chapter, and the various diseases in which it occurs are mentioned, together with the chief points of connexion between the symptom and the disease. Besides being described in the text, the disease is also referred to in the margin of the page, so that it is possible at a glance to see what diseases are associated with the symptom under discussion. The volume should be of real use to the physician in assessing the diagnostic value of a particular symptom.

EAR, NOSE, AND THROAT.

The Ear, Nose, and Throat in General Practice. By D. A. CROW, M.B., Ch.B. Edin., Oto-laryngologist to the Royal Sussex County Hospital and Sussex Throat and Ear Hospital. Oxford Medical Publications. London: Humphrey Milford, Oxford University Press. 1927. With 2 coloured plates. Pp. 160. 10*s.* 6*d.*

THE subtitle of this little book is "an informal guide to the main principles," and the author's intention is the laudable one of stimulating the interest of the general practitioner in those diseases of the ear, nose, and throat which are commonly encountered in his work. Dr. Crow rightly lays great stress on the prompt performance of paracentesis of the drum in cases of acute otitis, and considers that he will not have written in vain if, as a result, a single practitioner proceeds to incise a single eardrum. In the attempt to avoid wearisome detail, perhaps too much has been omitted; there is no description of either Rinne's or Weber's test, and no account of the use of the Siegle speculum. The acute ear is well described from the practical point of view, and two important points are emphasised—namely, that a mastoiditis exists concurrently with almost every case of acute otitis, and that the antrum should be drained when discharge persists undiminished, though many will consider the time-limit of ten days to be too short. The author's method has been to describe some of the commoner affections, and to group the omissions into a final miscellaneous chapter. The notes in this chapter are mostly too brief to be of much value, and they are badly arranged—for instance, a very short note on laryngectomy is sandwiched between one on tinnitus and one on vertigo, and Vincent's angina between this and aural cerumen.

The book is brightly and vigorously written, and will be useful. It cannot take the place of a text-book, even for the practitioner who desires a minimum of knowledge of these special subjects.

DISEASES OF THE INTESTINES.

By A. P. CAWADIAS, M.D. Paris, M.R.C.P., Senior Physician, Evangelismos Hospital, Athens. London: Baillière, Tindall and Cox. 1927. Pp. 300. 16*s.*

THE student who is unfamiliar with French, Italian, or Spanish medical literature will find pleasure and interest in this volume. He will discover much that is learned, much that is imaginative, and not a little that is ill-digested. But when full allowance has been made for the great difficulties that confront any author writing in a foreign language, it will be agreed that Dr. Cawadias has produced a work scientifically conceived and well illustrated, and requiring only drastic editing to make it a real addition to our literature. The bibliography is an excellent and original one.

PATHOLOGY OF THE NEW-BORN.

Biologie und Pathologie des Weibes. Edited by JOSEF HALBAN and LUDWIG SEITZ. Section 37. Berlin and Vienna: Urban and Schwarzenberg. 1927. Pp. 314. M.22.

WITH the exception of a short article by Prof. M. Stickel on asepsis in obstetrics, this section of Halban and Seitz's comprehensive work is devoted to the new-born infant. It consists of two parts, on the physiology and the pathology of the new-born, both by Prof. A. Reuss, of Vienna. The first part describes in considerable detail the peculiarities, anatomical and physiological, of the infant at and after birth, paying special attention to the stage of development reached by the various systems, and the alterations in the blood and viscera which accompany the establishment of independent existence. The second and larger part gives a comprehensive, and at the same time readable, account of clinical disorders met with in the first weeks of life, as well as of congenital malformations. It is fully up to date, and contains much well-chosen material which has not as yet found its way into most text-books. This is particularly exemplified by the account of intracerebral birth hæmorrhage, and its immediate effects, based on the work carried out at Frankfort by one of the editors (Dr. Seitz) and P. Schwartz, and containing illustrations drawn from their works. The whole volume is profusely illustrated, and an exhaustive bibliography renders it a valuable book of reference.

TEETH AND HEALTH.

By J. SIM WALLACE, D.Sc., M.D., L.D.S., Lecturer on Preventive Dentistry, King's College Hospital. London: Faber and Gwyer. Pp. 214. 3*s.* 6*d.*

THIS book, which is one of a series of modern health books, under the general editorship of Prof. Fraser Harris, intended for the general public, is an excellent example of what such a book should be. Clearly written, in language sufficiently free from technical phrases to be easily understood, it sums up the present state of our knowledge, and indicates the broad lines of preventive dentistry. Dr. Wallace has himself made notable contributions to the ætiology and prevention of dental disease, and, as might be expected, the views with which his name is associated receive full discussion here. If we have a criticism to offer, it is that perhaps he over-emphasises his own views

and does not state sufficiently the views of other workers which do not coincide with his own. Those familiar with dental literature are aware that Dr. Wallace is opposed to the view that defective structure of the teeth is a factor of importance in dental caries. In a book designed for general reading we feel that it would have been wise to mention other views which are held to shed light on the prevalence of caries, and to offer a possible way of diminishing its incidence. But this one-sided attitude does not detract seriously from the merits of a book which is well written, well produced, and cheap. A few more illustrations might with advantage be added in future editions.

DIAGNOSIS OF PANCREATIC DISEASE.

By ROBERT COOPE, M.D., M.R.C.P., Senior Assistant Physician, Royal Southern Hospital, Liverpool. London: Humphrey Milford, Oxford University Press. 1927. Pp. 112. 5s.

THE Rogers prize essay of the University of London is reprinted in this volume. The ætiology, symptomatology, and clinical findings in pancreatic disease are fully and logically described. The laboratory findings are discussed with critical acumen, and the book will be found useful by all interested in the subject.

Messrs. Jackson, Wylie and Co., Glasgow, have published in pamphlet form, as No. IX. of Glasgow University Publications, the Macewen Memorial lecture on the Meningiomas, delivered in Glasgow last June by Dr. Harvey Cushing, professor of surgery in Harvard University. The latter part of this lecture appeared in THE LANCET of June 25th, 1927; the earlier part, which now appears for the first time, deals with the traditions of the Glagsow School of Surgery and describes certain of the hitherto inoperable meningiomas arising from the floor of the anterior cranial chamber.

JOURNALS

ARCHIVES OF NEUROLOGY AND PSYCHIATRY. Vol. IX., 1927. Edited by FREDERICK L. GOLLA, F.R.C.P., M.B. Oxf. London: P. S. King and Son, Ltd. 1927. 15s.—This year's Archives are prefaced by an obituary of Sir Frederick Mott, reprinted from THE LANCET (1926, i., 1228), a bibliography of his works, and his Harveian Oration for 1925; it also contains three of his latest studies—those on the larynx of the Siamang Gibbon, the adrenals in dementia præcox, and the pituitary gland in asylum and hospital patients. All the 30 papers in the volume have appeared in various journals during the last three years, and all represent the patient work of first-class investigators into the fundamentals of insanity. Three of them, one of which appeared in THE LANCET for April 17th, 1926, deal with encephalitis lethargica; Dr. P. K. McCowan writing, with others, on the variations in the blood picture and the effect of hyoscine on the carbohydrate metabolism of patients; and Dr. A. Hancock on changes in the cerebro-spinal fluid. Dr. Isabella Robertson contributes two articles, and Dr. A. A. Petrie one, on circulatory abnormalities in psychotic patients, particularly the hæmoclastic crisis, a reaction to the injection of milk: this promises to be of diagnostic value in some of the psychoses, especially dementia præcox. Neurology is represented by the work of the editor on variations in the time relations of tendon reflexes, and on the electrical recording of voluntary movement, and by that of Dr. McCowan on the physico-psycho-galvanic reflex. The treatment of dementia paralytica by malaria is discussed in a report from the research team of the London County Mental Hospitals, the headquarters of which are now at the Maudsley Hospital, under the new organisation (described by the editor in a foreword to the volume). The value of tryparsamide in the same disease appears from the account given by Dr. W. S. Dawson of his results; this appeared in our issue of May 23rd, 1925. Dr. Dawson also contributes, with Dr. Mary Barkas, a paper on the somnifen treatment of the psychoses; and Dr. Barkas writes with equal lucidity and knowledge on the contribution of psycho-analysis to the treatment of mental patients, tonic spasm of the eyes in conjugate deviation, and the significance of social conditions in the ætiology of mental disorder. Dr. McCowan, in addition to the articles already mentioned, reports four cases of pellagra, and contributes a study on the circumvention of the typhoid carrier. Mr. S. A. Mann, in his paper on the lævulose test, indicates the necessity for eliminating a bewildering number of factors unconnected with hepatic insufficiency before the finding can be relied on as an aid to diagnosis, and casts doubt on the results of former investigators. Other contributions deal with the neutral sulphur excretion after the ingestion by dementia præcox patients of sodium thiosulphate, the cerebro-spinal cholesterol in certain mental diseases; and an account of a case of herpes apparently due to invasion of the ganglia by round-cell sarcoma. The work of the inquirer would be facilitated if this admirable collection were paged consecutively.

JOURNAL OF INDUSTRIAL HYGIENE. September.—Two long and useful articles appear in this issue. The first, on health hazards in the cotton industry, is the first instalment of Dr. W. F. Dearden's Milroy Lectures (1927). Mortality figures are given showing that the health of cotton operatives on the whole is but slightly below that of the standard for the kingdom; but certain groups—e.g., those opening the bales of cotton and employed at carding engines—are found with high mortality from respiratory diseases, particularly bronchitis. Estimates of the sickness incidence by Dr. Dearden tend to substantiate these figures. The records of the medical officers of health for Blackburn convey the impression that weaving must be considered a healthful occupation particularly for women. Much discussion and research has been directed to the effect of temperature and humidity upon cotton operatives, and the whole of the subject is completely summarised with a description of the processes concerned in the manufacture of cotton goods from spinning to weaving. As the temperature rises above 72° F. the thread benefits by a rise in temperature which is physiological and disadvantageous. Cotton operatives are said to enjoy freedom from the ill-effects of high blood pressure, this freedom being ascribed to removal of waste products of metabolism by sweating. A number of observations are given to establish what are the atmospheric conditions normally existing in the mill and methods are described by which these conditions can be ameliorated without interfering with production.—The second article is based on a clinical study of the effects of mine gases. The writer, R. Herndon, had under observation 145 men who's disability was ascribed to exposure to abnormal conditions of the air in coal-mines. Frequently the disability was due to concurrent disease, while the condition most often causing trouble was ascribed to stagnant air. Bad air—i.e., air containing poisonous gas—was less frequently to blame. Carbon monoxide was the most common gas causing disability. A valuable summary of knowledge with regard to carbon monoxide poisoning is given, and we are reminded that plants and insects (which have no hæmoglobin) are essentially unaffected by CO, while brain cells grow profusely in an atmosphere of 79 per cent. carbon monoxide and 21 per cent. oxygen. Carbon monoxide acts by depriving the tissues of oxygen. All symptoms can be explained by this action, particularly since the cerebral cells exhibit great susceptibility to lack of oxygen. Indeed, nerve cells after temporary deprivation of oxygen may never thoroughly recover. Other gases occurring in mines such as CO_2 and methane are of little importance, but occasional nitrous fumes arising from incompletely detonated explosives may cause fatal accidents. Interesting histories are given of 11 typical cases seen by the author.

THE LANCET.

LONDON: SATURDAY, OCTOBER 29, 1927.

CHRONIC GASTRITIS.

To many practitioners gastritis is a disease occurring with great frequency amongst their patients, whilst others look upon it as so rare as to be almost non-existent. It is true that there is no text-book on medicine published in any civilised country which does not devote a considerable amount of space to describing the condition, but on the other hand these statements do little to enable even the experienced clinician to diagnose it with any certainty. Clearly, then, gastritis is an obscure disease, and the more interest therefore attaches to Prof. KNUD FABER'S Schorstein Lecture published at length in our present issue. Prof. FABER is an authority on this subject, to which he has devoted peculiar attention, and few can read his lecture without increasing their knowledge and finding some fresh stimulus to observation.

Gastric analysis, when first introduced, turned the attention of the medical world to the outstanding disturbances of secretion—hyperchlorhydria and anacidity. But these, as Prof. FABER points out in his introductory paragraphs, cannot properly be regarded as diseases. They are at most symptomatic, and he proceeds to discuss the relation of each to the actual disease—namely, gastritis. In earlier times the term gastritis was equivalent to "catarrhal inflammation of the stomach," but to-day it is recognised that besides damage to the surface of the organ by various noxious agents, it is possible, and very likely easy, for the deeper layers of the stomach to be injured by toxic agents arriving by way of its blood-vessels. Thus the gastric secretion may be impaired by diffuse lesions of the glandular parenchyma or ulcerations of the surface which take origin in necroses beginning in the deeper layers. Prof. FABER for this reason believes that the stomach undergoes pathological changes akin to those seen in the inflamed liver or kidney. His views on the pathogenesis of achylia gastrica are both interesting and original. He holds that achylia is always the result of chronic gastritis, which in its turn is often due to widespread and deep-seated hæmatogenous inflammation, following an infectious fever during childhood or even in early infancy. In extensive histological studies, carried out with special precautions to avoid the failures associated with rapid post-mortem disintegration of the gastric mucosa, he has observed inflammatory changes in the stomach at all ages and of sufficient degree to support his theory about their effect on secretion. Again, he has been able to observe achylia, severe in degree but temporary in its manifestations, occurring especially amongst children recovering from severe infection. In a statistical study embracing many hundreds of cases he demonstrates that achylia becomes much more common as age advances, and this he considers evidence in favour of his view that it is a phenomenon secondary to infectious disturbance. He attributes our general lack of knowledge of the subject to the fact that gastritis is essentially "silent"; it is well known, for instance, that alcoholic gastritis—which he calls "the one form of the disease commonly due to agents acting on the surface of the stomach"—can produce violent symptoms for a time, and then leave the patient with complete achylia, yet apparently in perfect health. Gastric digestion can be completely replaced by pancreatic digestion, and only the stomach tube or histological section may demonstrate the chronic inflammatory changes still present in the stomach. The grave sequelæ of achylia are indirect and tend to show themselves outside the intestinal tract, the withdrawal of the disinfecting properties of hydrochloric acid occasionally leading to diarrhœa and anæmia.

The second part of the Schorstein Lecture is concerned with the relation between hyperacid secretion and gastric ulcer. The syndrome of REICHMANN, which consisted of hyperacid gastric secretion associated with post-prandial pain, is now universally recognised as a usual accompaniment of ulceration of the stomach or duodenum, but, as Prof. FABER points out, it has lately become more and more evident that the "syndrome pylorique" described by G. SOUPAULT and ALBERT MATHIEU is not invariably associated with an ulcerative lesion, and such cases, in his opinion, are usually the result of juxta-pyloric gastritis. This view he apparently bases on histological material obtained at operation. Macroscopic examination gives little evidence, but the microscope has revealed much inflammatory change amidst the normal material. Wherever there has been actual ulceration, says Prof. FABER, the other changes are to be found, and from these observations he concludes that the oldest hypothesis concerning the pathogenesis of gastric ulcer, that advanced by CRUVEILHIER, is once more coming to the front—namely, that gastritis is the preceding cause of gastric ulcer, and that ulcerative pyloric gastritis is the cause of all juxta-pyloric ulcers.

There is much that is controversial in the lecture. Prof. FABER seems, for example, to reject altogether the embolic view of the origin of peptic ulcer, although it is not wholly out of harmony with his general opinions on the frequency and importance of inflammatory gastric lesions. But the challenging nature of his views in itself gives them importance, and without expressing strong approval or disapproval of them we take pleasure in setting them fully before our readers.

THE HEREDITY OF CANCER.

THE question whether cancer is hereditary is of manifold importance. The clinical evidence in the human subject gives no convincing indication of the disease being inherited. Occasionally cases are reported where several members of a family have succumbed to the disease; but the rarity of such an incidence as compared with the large number of deaths from cancer may be taken as an indication that in man heredity does not play a significant part in the genesis of cancer. Life insurance companies, which have a financial interest in the matter, do not attach any importance to a cancerous ancestry.

The evidence from man, however, does not dispose of the problem, for in man the ancestry, from the point of view of the incidence of cancer, is always mixed. This difficulty is not present in breeding experiments among the lower animals; and in order to obtain evidence of the appropriate sort experiments in inbreeding among mice of known cancerous ancestry have been performed. The first observation along these lines by E. E. TYZZER and by J. A. MURRAY gave a clear indication that under exceptional conditions a

hereditary factor exists which is probably of the nature of a predisposition to cancer. The most extensive observations dealing with this point are the breeding experiments of MAUD SLYE, continued since 1914. These laborious and careful observations, recorded in a large number of papers, have been interpreted by Miss SLYE as demonstrating that cancer is transmitted by inheritance along Mendelian lines. Dr. E. A. COCKAYNE now points out[1] several fallacies which invalidate Miss SLYE's conclusions. He agrees that both in mice and in men there are disorders of growth which are inherited and on the basis of which cancer may develop. But he continues, "most of these disorders of growth are rare, and it seems unlikely that the proportion of cancer arising from them to the total number of cancers in the general population can be a high one, but other unrecognised disorders of a similar kind may be more numerous than is at present suspected, and until their existence has been proved or disproved, their importance in the production of cancer cannot be assessed. . . . Experiments on animals show that an inherent cell defect is not necessary for the production of malignant growths. . . . There may be an inherited susceptibility to cancer in normal tissues, and in the case of some animals there is already experimental evidence to this effect, but at present it is too scanty and too incomplete for it to be reviewed with advantage. Whether it plays a part in the case of human cancer, and if so, how great a part it plays, are questions still more problematical and still less ripe for discussion." The paper, which contains a number of interesting data, is closely reasoned and will repay careful study.

We take this opportunity of drawing attention to the *Cancer Review* now completing the second year of its existence. This journal, which is published under the auspices of the British Empire Cancer Campaign, presents to the reader a critical commentary on the current literature of cancer by means of abstracts of the more important papers and by occasional reviews on selected subjects. The editors, who are experts in the various branches of cancer research, are also the abstractors. A careful annual index adds greatly to the value of the journal. It is difficult for the non-expert to find his way through the literature on cancer, not merely because it is very extensive, but because so little of it is good and reliable. Much of it is so highly technical that only those engaged in similar work and conversant with the technique can express an opinion on its value. By serving as a sane and reliable guide the *Cancer Review* is fulfilling a useful and important function. Maintained at its present level it will become the standard work of reference on cancer.

THE PANEL DOCTOR AND THE MINISTRY.

LAST year's annual conference of Local Medical and Panel Committees empowered the Insurance Acts Committee to negotiate with the Minister of Health on certain proposals to modify disciplinary procedure under the Acts. This procedure has caused alarm, friction, and mistrust ever since the Ministry replaced the Health Commissioners. Certain decisions made by the Minister have aroused strong demands for a direct appeal to the High Court against his judgments, and whilst the Insurance Acts Committee and the majority of the conference recognised that there were objections to this proposal, it was obvious that some safeguard against arbitrary action by the executive was urgently needed. This feeling was reflected in a limited resolution by the 1926 conference that there ought to be an appeal to the courts on the grounds of irregular procedure, or alleged vindictive penalty, and where a common law action by the patient would normally lie, whilst the question of appeal in other cases was left to negotiation between the Insurance Acts Committee and the Ministry.

After keen debate at its meeting last week the Panel Conference agreed to give three years' trial to a scheme summarised by Dr. H. G. DAIN, Chairman of the Committee, in a speech which we report on p. 933. The essence of this scheme is to provide representation of the panel doctor on every body which considers complaints against him. One of the chief grievances of the practitioner has been that the progress of every case, between the hearing by the Medical Service Subcommittee or the Committee of Inquiry and the decision of the Minister, has been shrouded in an impenetrable mist, and it is to be hoped that this will now be dispelled. A panel doctor, chosen by the Insurance Acts Committee, is to be present at the hearing by the insurance committee, and at the hearing of the appeal (if any) whilst three doctors, chosen by the Minister from a small panel nominated by the Insurance Acts Committee, are to constitute with the chief medical officer of the Ministry and his two assistants, a new Joint Advisory Committee to help the Minister in his final decision. Among other reforms, the Minister agrees to instruct insurance committees to see that charges are made as specific as possible, and to forbid their clerks to act as prosecuting counsel in cases sent by them, or by the Medical Benefit Subcommittee to the Medical Services Subcommittee. The best shorthand writer on the insurance committee staff is to attend the proceedings before the Medical Services Subcommittee and take notes from which the clerk will prepare a full memorandum; before this memorandum is circulated to the insurance committee it will be submitted to the members who were present at the hearing. The Medical Service Subcommittee besides being able to recommend the withholding of a grant, the removal of a patient from the doctor's list, the limitation of the list, or the removal of a doctor from the panel, may now recommend that a doctor be warned or censured, and it is hoped that insurance committees may in practice send such recommendations instead of advising the Minister to withhold a grant. The Minister's power to withhold grants without instituting an inquiry is now limited to cases of failure to keep proper records, or to return Form R.2, or to notify cases of tuberculosis; and except where a doctor has been convicted of a felony he agrees not to order an inquiry without any representation from a medical service or joint service subcommittee. A minor source of dissatisfaction has been removed by a new clause imposing on complainants a time-limit of eight weeks, after which no committee will be allowed to investigate a case without the Minister's express approval.

Bureaucracy, of which lately there have been frequent complaints, voiced particularly by the Lord Chief Justice, takes two familiar forms. One is the excessive recourse to rules and regulations, the other is the tendency to elevate a department or a Minister into a judicial tribunal from whose judgments there is no appeal. The fear of departmental government lies behind the criticism, levelled by delegates to the conference, that the scheme is not watertight. The Minister, it was argued, will not be compelled to accept the advice of the new body, and

[1] The Cancer Review, October, 1927.

since he does not bind himself to nominate members of the panel in rotation, he will be able to select those who prove complaisant to his wishes. The right of appeal to the courts, said the scheme's opponents, was the only effective safeguard against injustice. As a whole, however, the conference felt that the new proposals were sound and ought to work, assuming goodwill and the intention to play fair on both sides. If the parties are not going to follow the ordinary rules of straight dealing, then no machinery is likely to run smoothly; the success of any scheme depends largely on the men who work it. If the Minister of Health, whoever he may be, should so lose sight of the general good as to ignore the Advisory Committee or make its function negligible, or if the representatives of the panel should fail in their obligation to protect the doctor from the admission of unfair evidence or irregular procedure at the various stages of an inquiry, then it will be necessary to find some other way. But it would be unfair to assume such failures at the outset. Little harm can be done in three years, and there will be a general desire to find in the new arrangements a convenient means of securing justice.

Annotations.

"Ne quid nimis."

HYGIENE FOR SEAMEN.

SEAMEN in the mercantile marine seem to be coming into their own at last. Their grievances were first seriously voiced in 1894. In that year Sir W. Forwood, chairman of a conference of the Sanitary Institute at its Liverpool Congress, described "the old fo'c's'le, right in the bows of the ship, often not more than 4½ or 5 ft. high, cumbered up with windlass, chain cables, and hawsers, flooded with water, which rushed through the hawsepipes every time the ship plunged into the sea, destitute of sanitary conveniences of any kind, and filled with the hot steamy atmosphere of bad tobacco and damp, drying clothes, for which there was no escape, as there was no ventilation whatever; no wonder that existence in such dens degraded the life of a seaman." He was followed by Dr. W. Collingridge, M.O.H. of the Port of London for the previous 14 years, who in his time did much to prevent infectious disease from entering the country from abroad, to stop typhoid fever being spread by oysters, and to clean the kitchens of City restaurants. Dr. Collingridge, in a paper on the hygienic needs of seamen, which we published on May 5th, 1894, asked for many improvements on ships, which few readers of that day could have thought other than Utopian. He asked that the men should be berthed in deckhouses if not, that meanwhile a forecastle should be 6 ft. high at least, with cork paint over its naked iron, no capstan in it nor ship's stores, ventilation and better heating, and for the men larger cubic space, good water-closets, and—in the larger ships—a hospital. The provision of good drinking water was insisted upon, as well as a fair scale and certificated cooks. All these the seamen now have, though they have had to wait years for them. Conditions are enormously improved to-day, and we have statistical evidence thereof in the annual report by Dr. A. A. Mussen, M.O.H. to the Liverpool Port Sanitary Authority, which is reviewed elsewhere this week. Dr. Mussen has a record index of the ships that visited that port in 1926, and prints a table showing the seamen's accommodation in 317 ships built before 1916 and 316 built since. We need only refer in detail to the first group, made up of large cargo ships with white crews, 187 built before, 211 since 1916. In the 187 earlier ships 104 (55 per cent.) housed their crews only in the forecastle, 39 (20 per cent.) berthed them only aft. But in the 211 built since 1916, 39 only (18 per cent.) housed their men forward and 149 (70 per cent.) berthed them all aft. The benefit of the change is, in Dr. Mussen's words, "more room, ventilation and lighting better, less dampness and weather damage," and, we may add, far less misery in storms. But this taking of the seaman out of the forecastle is not all that has been done. Nearly all new ships have wash-places, two in every three ships have messrooms, half have hospitals, one in every four cubicles, and 7 per cent. baths. These are great advances, and there would appear to be a definite intention on the part of shipowners to afford to seamen in their ships comforts approaching those of their brethren on shore.

To some extent, we suppose, the shipowner did not know how badly off his seamen were, and for this reason we have made our recent endeavours to enlighten him. The Royal Sanitary Institute has inculcated similar lessons through expert advice, and the medical officers of health of Port Sanitary Authorities, who saw with their own eyes how sanitary standards afloat lagged behind those on shore, have told the same story from the medical standpoint. The Board of Trade, with no medical staff, has helped of recent times to improve seafaring conditions, deriving its knowledge of hygiene from the Ministry of Health and the Port Sanitary Authorities. There is real willingness, therefore, being displayed to give seamen the same advantages as those enjoyed by other citizens, and we look forward to a provision that plans of ships should be approved by the local Port Sanitary Authority before construction is begun, realising that ships are the dwelling-houses of those who sail on them. With improving conditions we may expect that the returns of deaths among seamen may be trustworthy, and regularly collated and published. The duty of the officers of the medical service in the mercantile marine has, on some of the ships employing a doctor, been carried on in distasteful and unpromising circumstances, even while in the large companies the necessary reforms have been long made. We review the conditions of this service on page 936, and draw attention to the opportunities which it offers. These doctors, by coöperation with the port medical officers, can help to keep alive the determination to raise the hygienic and sanitary standards on all our merchant ships.

JEAN NICOLAS CORVISART.

IN his inaugural thesis[1] on Corvisart and cardiology, which contains a portrait of this great French clinician, Dr. J. M. Lassus maintains that Corvisart, whose fame has been cast into the shade by his pupil Laënnec, was the founder of French clinical medicine at the dawn of the nineteenth century. He was first and foremost a cardiologist. Before his time it was only the anatomical lesions of pericarditis that had been carefully studied, and Sénac (1693–1770) alone had undertaken a systematic study of affections of the heart. In his work entitled "Essai sur les maladies et les lésions organiques du cœur" Corvisart emphasised the following facts: (1) the frequency of organic lesions of the heart; (2) the necessity of distinguishing functional disturbances from definite organic lesions; and (3) the necessity of having a cardiac symptomatology essentially founded on percussion, for which he was indebted to Auenbrugger. In his clinical account of what he called "Aneurysms of the Heart"—i.e., cardiac insufficiency—he was the first to describe the dyspnœa caused by exertion and the palpable thrill of mitral stenosis. But his work principally emphasises the importance of the following: (1) the distinction between hypertrophy and dilatation of the heart; (2) the occurrence of three successive periods in the course of cardiac insufficiency; and (3) the causal connexion between valvular lesions and cardiac failure. Lastly, in his insistence on the importance of comparing the symptoms found during life with the lesions present after death, Corvisart may be regarded as the founder of anatomo-clinical cardiology.

RELATIVE VALUES IN PUBLIC HEALTH WORK.

IN his inaugural address last week as President of the Society of Medical Officers of Health, Dr. James Wheatley, medical officer of health for Shropshire, put forward with vigour and eloquence a new conception of public health. We cannot afford, he said, to interfere with the health and vigorous development of the body and mind of a large proportion of the people in order to prevent a few accidents. Two instances he gave in illustration of this thesis were the freedom with which German children were allowed to swim in the Rhine, to the infinite advantage of their health and physique, although the casualty list might be considerable; the other, the routine removal of the newly born child from its mother's side to a cot, to avoid the occasional risk of overlaying, overlooking the risk to the welfare of the child of forfeiting the uniform warmth of the mother's body for the first three days of independent existence. The great importance of infant welfare work as at present conducted is, according to Dr. Wheatley, not so much the preservation of infant life as the production of a healthy adult population. The best guide to physical progress would be found, he is satisfied, in tests of physical fitness which, if made universal, would result in rapid advance of physical development and general health. To point his lesson further he took the recent work on the prevention of diphtheria and scarlet fever. Are we, he said, to Schick and Dick everyone? or are we to space and ventilate better and ever better so as to bring vital sunshine into our schools and homes, reserving these two tests and inoculations for emergencies and special conditions? That great sanitary reformer, Sir John Simon, noted nearly 70 years ago the possible danger of reducing disease while leaving the primary cause intact. Suppose, said Dr. Wheatley, dental caries could be prevented by the use of the toothbrush and it became possible by such an artificially short cut to abolish the disease, whilst leaving defective diet and wrong habits unremedied, would such eradication be a benefit or a calamity to the community?

Following up this thought, Dr. Wheatley went on to speak of the need critically to examine the advice of the consulting physician whose experience is entirely with sick and abnormal persons, and to emphasise the importance and lasting value of work which tends to improve the living of the ordinary individual. If open-air methods were advisable for the victims of our present bad hygienic conditions, how much more the need to provide open-air schools for the whole population of school age. The practical difficulty is that of heating, for any method which heats the air is rendered useless by the rapid change, and radiant heat is too unequal. The adoption of the open-air principle in school construction must depend, he said, upon the effective and economical solution of floor heating. Attempting to assess health factors in their relative importance, Dr. Wheatley put in the first place research in its widest sense. We are, he said, benefiting enormously at the present time through modern physiological research; inquiry into the causes of the fall in the death-rate from tuberculosis during the last 50 years is much overdue. Second in importance he placed the education of the people which, to be effective, would require a vastly improved system of health visitors and district nurses to give instruction in the homes. Antiquated restrictions on the nursing of infectious disease must give way to the modern view that a large proportion of ordinary ailments are infectious and that the spread of infection by nurses can be prevented by simple precautions. Incidentally he put in a good word for open-air bathing and sun bathing, the demand for which, he thought, would increase enormously in the near future. Dr. Wheatley concluded an instructive address by pleading for a wider conception of the position and responsibilities of the medical officer of health. Efforts to improve the defective and diseased person, good enough in themselves, must not take precedence over the general measure so vastly more important for the prevention o disease.

Dr. Wheatley did not give a new name to hi teaching, but such a name has been supplied by Pro Stan. Ruzicka, of Bratislava (Presburg) Czecho Slovakia, who has just reissued a System of Hygien which attracted attention some years ago and whic he calls "eubiotics." Dr. Ruzicka, who edits th Czecho-Slovak *Journal of Hygiene*, teaches that huma life must be supported on physiological principle Briefly, his remedy is to remodel cities so as to mak them mere centres of business and public life t which workers will be conveyed each morning fro their rural dwellings, returning at night to their ow cottages, gardens, and farmyards, and in his pamphle he contrasts in parallel columns the life of a famil in the town with that of a family in the countr with a minimum of 2000 square metres of cultivate ground. The chief difficulty he foresees, even i Czecho-Slovakia, is the cheap and rapid means of tran port from the garden city to the business centres, difficulty which would be vastly accentuated in an country where Nature does not provide a chea method of producing electric power. Nevertheles his system of eubiotics is worthy of more than passing thought.

DISPENSARY TREATMENT OF TUBERCULOSI BY ARTIFICIAL LIGHT.

THE treatment of tuberculosis by the vario forms of artificial light has hitherto been carried o almost exclusively at residential institutions, or in t out-patient departments of the larger hospitals. May, 1925, the Lancashire County Council decide that experiments should be carried out to determi whether ultra-violet ray therapy might be profitab employed in connexion with the county dispensa service. Experimental light centres were according established at the Ashton-under-Lyne and Lancast Dispensaries in the summer of 1925. An account the methods employed, the types of cases treated, a the results of treatment at the two centres betwe the opening of the centres and the end of 1926, included in an instructive report by Dr. G. Lissa Cox, central tuberculosis officer of the county. T experience of Dr. Cox and his colleagues sugges that the lamps most suitable for dispensary use a the long-flame carbon arc, the Jesionek mercur vapour, and the Kromayer water-cooled mercur vapour lamp, the two former being employed f general, the latter for local treatment. Of 1 patients treated at the Ashton Dispensary up to t end of 1926, who with few exceptions were sufferi from tuberculosis of skin, glands, joints, or bon it is claimed that 91 cases could be classed "quiescent and apparently cured" after the ligh treatment. Dr. Stewart, the medical officer charge of the centre, estimates that, but for t dispensary treatment, 60 of these would have bee admitted for ordinary institutional care. A com parison of the estimated cost of the dispensary a institutional treatment has been made, and it claimed that the dispensary treatment has result in a saving of no less than £850 for this group patients, a striking figure when contrasted with total initial outlay of £333 on plant. The best resul from treatment have been obtained in cases of lup and adenitis (with abscess formation and skin involv ment). Of the former, 48 cases were treated Ashton with 21 apparent cures, of the latter 29 cas yielded 26 cures. It is stated that many of the lup cases had been under treatment "for so long 20 to 40 years prior to commencing light treatment The tables setting out the results of treatment inclu six cases of "bronchial glands," presumably the se of active tuberculous disease. After treatment wi carbon-arc lamps three of these were stated to "quiescent, apparently cured." A further comme

[1] From the author, Hygienic Institute, Bratislava.

is made that "cases of bronchial gland tuberculosis have done very well, and the X ray evidence tends to support the view that the light has had a favourable effect, although one is naturally cautious in drawing any definite conclusions, as it is possible the improvement might have taken place without the light." Now it is notorious that the diagnosis of tuberculous infection of the tracheo-bronchial glands can seldom be made with any degree of certainty. To determine by means of X rays or physical examination that an active lesion in this situation has become quiescent is in the present state of knowledge impossible. It is, therefore, undesirable to include statistics for a disease which can only be suspected, in tables devoted mainly to surgical tuberculosis of which the diagnosis is usually patent. A further assertion to the effect that "tuberculous eye conditions seem to respond very well to general treatment" is unsupported by evidence. Although one case of phlyctenular conjunctivitis is reported as cured, the assumption that this condition is tuberculous is not warranted.

We recommend all those whose work brings them into contact with the tuberculosis service to read Dr. Cox's report on the results obtained in the course of an interesting and very hopeful experiment.

THE LONGEVITY OF CRICKETERS.

IT is a deep-rooted belief that first-class athletes tend to die relatively young, but Mr. A. Bradford Hill, D.Sc., in a study from the National Institute for Medical Research (which appears on p. 949) shows that this belief is not well founded as far as cricket is concerned; a strict analysis based upon data in Wisden's "Cricketers' Almanac" makes it clear that cricketers are long-lived in comparison with the general population. Dr. Hill is here dealing only with cricketers of British nationality born since 1888, and his analysis terminates in 1913 in order to avoid the disturbing influence of the years of war. Taking his analysis a little further Dr. Hill finds that amateurs have a slight advantage over professional players in regard to longevity, the explanation no doubt being that while the amateur shares with the professional the advantage of physical selection he has in addition the benefit, as regards length of life, of social selection. The statistical analysis on which Dr. Hill's conclusions are based, although far more complete than any which has hitherto been made, was foreshadowed by figures given by a cricket enthusiast, Mr. Frederick Gale, some 45 years ago. Mr. Gale followed up the life-history of the so-called "B" eleven chosen by Lord Frederick Beauclerk to play against All-England. Of these 11 men the youngest died at the age of 69, while the others lived to various ages up to 95. In commenting on these figures Mr. Gale remarked that insurance offices would grow rich if no lives but those of cricketers were taken. It is not without interest that at the lecture in which Mr. Gale conveyed his observations, which were published at the time in our columns, the chair was occupied by Mr. Ruskin, then Slade Professor at Oxford.

SHELL-FISH SANITATION.

THE outbreaks of enteric fever and other gastro-intestinal complaints which have been traced from time to time to the consumption of shell-fish have seriously affected the prosperity of this industry in America. A conference held in Washington in February, 1925, led to the formulation of a scheme, described[1] by Mr. L. M. Fisher, a sanitary engineer in the U.S. Public Health Service; this scheme is promoted alike by the representatives of the health and commercial interests. The chief responsibility is thrown on the individual States, coördination and uniformity being secured by mutual agreements between the States with the help and advice of the Federal service. Under the scheme the shellfish-producing State examines the water, prohibits shell-fish being taken from unsafe water, gives licences for taking the shell-fish, inspects the marketing, packing, and shipping arrangements, and issues certificates to shippers who have complied with the State regulations. The State certificates are submitted to the Federal service, which, if satisfied, adds the name of the certified shipper to a list which is sent out twice a month to the health authorities in the various States. The success of the scheme depends upon the effectiveness with which the health authorities of the shellfish-consuming States admit to their markets only shell-fish which come from properly certified shippers. Mr. Fisher's article deals with other matters affecting the industry. Oysters thrive in a mixture of fresh and salt water, and the importance of the industry has in some cases led to the protection of estuaries from sewage pollution. The transfer of "seed" oysters from polluted waters to clean areas for development and maturity is mentioned as a danger, and the similar transfer of mature oysters as a still greater danger. In order that the oyster may free itself from impurity the temperature of the water must not be below 60° F., as a lower temperature interferes with the activity of the oyster, and prevents it cleaning itself. The examination of the water of the beds at frequent intervals is possibly a more reliable guide to safety than the examination of a certain number of the oysters. The practice of "fattening" oysters by removing them for short periods to fresher water and thus promoting osmosis brings added risk and has been prohibited by most of the oyster-producing States. The experiments which have been made to clean oysters by the use of chlorinated water have not so far met with approval and are compared to the "practice of pasteurising dirty milk." Mr. Fisher points out that there is a tendency amongst some of those engaged in the industry to make too much of the certification scheme as if it were an absolute guarantee given by the State and Federal governments, whereas the certificates refer only to the source of the oysters and the manner of packing at the point of origin. No responsibility is assumed for what happens to the oyster in its passage from the original shipper to the consumer. The progress of the scheme will be watched with much interest. In the past the careful conscientious oyster man has suffered from the doings of the less scrupulous producer. It is obviously of the utmost importance to the industry that the confidence of the public should be won.

[1] Public Health Reports, Sept. 16th, 1927.

ANOREXIA AND MALNUTRITION IN CHILDREN.

THE views expressed at a recent meeting of pædiatrists in Washington[1] suggested considerable divergence of opinion on the best way of combating anorexia and malnutrition in children. Dr. C. A. Aldrich, giving an account of his method of avoiding anorexia, and the theory on which it is based, laid stress on the distinction between hunger (a purely physiological function) and appetite, "a much more complex mental process dependant on pleasant memories of feelings, tastes, odours, and sights." The former, he said, merely initiates the taking of food; the latter controls the amount eaten. Transitory anorexia being usually the first symptom of an infection, whilst chronic anorexia results from the displeasurable feelings aroused by attempts to force the child to take food, Dr. Aldrich's invariable rule is to allow the child—even during infancy—to regulate the quantity of its feeds "with appetite as a guide." The success of this practice was shown by answers to a questionaire circulated to the parents, for it was found that on the average the children so treated were 3·6 lb. heavier than the normal for their age. In those who were under weight a definite physical cause for malnutrition was usually present. That there is much to be said, on empirical grounds, for Dr. Aldrich's line of treatment will be readily conceded

[1] Journ. Amer. Med. Assoc., Sept. 17th.

by many observers, though not all will admit the validity of the hypothesis on which it is based. His remarks seem to apply to children of all ages, expressly including infants on the bottle; and that so complex a mechanism as "appetite," according to his definition, should govern the quantity of food taken in infancy is an idea that will be accepted by few psychologists at the present day. Dr. L. W. Sauer described a routine treatment of underweight children of various types (excluding sufferers from diabetes and some special diseases) which is based on lines diametrically opposed to those advocated by Dr. Aldrich, and consists of a course of forced feeding lasting for three months and combined with periods of rest in bed. A five-meal diet is prescribed; afebrile children are started on an allowance of 40 calories per lb. of actual weight, which is raised until it approximates 40 calories per lb. of the theoretical weight for the height and age. Even vomiting is not regarded as a contra-indication. The results tabulated by Dr. Sauer show a gain of weight which is as striking as the rise in Dr. Aldrich's cases. His patients were of ages ranging from 5 to 12, and the psychological aspect of "appetite" might have been expected to play a more important part in their nutrition than in that of the series first described.

SANE ENOUGH FOR SENTENCE.

AT the recent Bedfordshire Assizes an inmate of the Three Counties Mental Hospital at Arlesey was convicted and sentenced for assaulting one member of the hospital staff and threatening another. In passing a sentence of two months' imprisonment the judge announced that he should assume that the accused man was sane. Possibly on this occasion the law was tempering justice with mercy; two months' detention in a normal prison is regarded as a lesser penalty than confinement for an indefinite period at Broadmoor as a criminal lunatic. Nevertheless, it certainly suggests that there must be something wrong with the law when an asylum inmate is sentenced as a sane man. This and other incidents raise the old disquieting doubts whether the law courts do not sometimes deliberately ignore the medical history of accused persons instead of obtaining the utmost possible information before passing sentence. The latest annual report of the Prison Commissioners contained some remarkable revelations of the tendency of certain magistrates to sentence a man first and to inquire into his mental condition afterwards. Persons, it appears, are not infrequently convicted and sentenced who are certified insane on their arrival in prison. A few months ago the Court of Criminal Appeal reaffirmed its rule of refusing to hear any fresh medical evidence in cases where the state of the accused's mind is a ground of appeal. The case of George Jordan, to which a correspondent draws attention in another column, seems to suggest the same attitude of judicial indifference to matters which, after all, may be as relevant to the issue of "guilty" or "not guilty" as any matters can be.

If the facts in Jordan's case are correctly stated, he was sentenced to 18 months' imprisonment by a court which did not adequately inform itself of his medical history and condition, and he was certified insane soon after he began to serve his sentence. If so, he was stigmatised as a criminal without sufficient consideration of his right to have the defence of insanity raised on his behalf. He recently committed suicide, and the coroner (Mr. Arthur H. Emanuel, of Southampton), having apparently access to medical evidence which must have made all the difference if it had been available in the criminal court by which Jordan was sentenced, observed that the case was one of the hardest and saddest in his experience. "By reason of his war service this man underwent injuries which made him assume the attributes of a criminal, whereas he was a splendid, honest man; for the sake of his wife and children some sort of representation ought to be made to the Home Secretary to remove the stigma of his having been made a criminal." When Parliament reassembles some Member will doubtless inquire of the Home Secretary what has been, or is proposed to be, done. The case looks like one of those which divide medical and legal opinion. The medical profession detects a series of symptoms which culminate in the climax of legal insanity; the symptoms and the climax are all stages of one disease; looking back upon the history of the case the supposedly criminal act is seen to have been the act of an insane man. On the other hand, the law courts and the Home Office will not admit that the earlier stages of mental disease can be accepted as lessening the criminal responsibility of the accused. The guardians of our penal system will not surrender the deterrent value of the hangman or the prison cell so long as the accused person has a lucid moment in which he can thereby be deterred. A kind of rough-and-ready give-and-take between the medical and the legal views is accepted by the public because it is believed that the legal view is applied with the utmost humanity and with full and enlightened use of the best medical information. If cases occur in which humanity is offended and medical information is ignored, the public may be roused to a sense of the limitations of the legal view.

COLOUR VISION.

A COMMITTEE of the British Association, consisting of Sir Charles Sherrington, Prof. H. E. Roaf, Dr. Mary Collins, and Dr. F. W. Edridge-Green, have issued a report on colour vision, with particular reference to the classification of colour-blindness. Any reference, implicit or explicit, to any theory of colour-blindness is carefully excluded, and it is recommended that the terms protanopia, deuteranopia, and tritanopia be abolished. Colour-blindness is defined as any marked decrease in sensitivity to a special region of the spectrum—e.g., to red—and it is recommended that if possible the precise wave-lengths involved should be specified. Failure to discriminate colours should be described not as colour-blindness, but as colour confusion—the number of distinct colours which are recognised in the spectrum being a rough measure of the degree of colour discrimination. All those persons who recognise only two colours in the spectrum possess a neutral region in which no sensation of colour exists. Its position and extent should be determined.

HOSPITALS AND MOTOR ACCIDENTS.

ALMOST every hospital in the country is faced by more or less serious difficulties as the result of the steadily increasing number of accidents caused by motor traffic. Sometimes it is the occupants of the cars who are injured, often seriously; sometimes it is the unlucky pedestrian who suffers. Whichever it is, the result is the same for the nearest hospital. However acute the difficulty of finding room, the sufferer has to be taken in and tended; the general experience is that, on the average, he occupies a bed for a longer period than the ordinary patient; and his presence may delay the reception of a patient who has been waiting for admission, perhaps for months. This is the human side of the problem, but there is also a serious financial side. More often than not these sufferers from motor casualties make no offering to the institution that has put them on their legs again, and the companies in which they are insured refuse to pay anything on the ground that hospitals are voluntary institutions and are therefore unable to sustain a claim at law. Obviously the situation cannot be left there, and the hospitals, in self-defence and in the interest of those who have what may fairly be described as the first claim upon them, will be compelled to find some means of self-protection. The Norfolk and Norwich Hospital, the waiting-list of which is being heavily encumbered by the results of motor accidents, seems to have found an ingenious

way out. A recent meeting of the governing body was reminded that a private practitioner, to whose surgery the victim of a motoring accident is taken, can send in a bill for his services, and it was pointed out that the hospital could place itself in the same position by sending all such cases to the new paying ward which is to be opened early next year. Whether the authorities of the Norfolk and Norwich Hospital have taken legal advice on the subject is not stated, but it is difficult to see how the motor insurance companies could repudiate a liability incurred by their insurers towards a body which is entitled to make, and notifies that it will make, a charge. The companies declare that if they accepted a liability towards the hospitals they would have to increase their premiums, but that seems very much like an admission that their beneficiaries are obtaining advantages for which they have not paid. The action of the Norfolk and Norwich Hospital, supported as it will probably be before long by other institutions, seems to point to the natural solution of a problem which of late has gravely increased the difficulties, both of means and accommodation, of the voluntary hospitals.

CLINICS FOR INDUSTRIAL RHEUMATISM.

AT the Annual Conference of Insurance Committees, held at Harrogate last week, Mr. Henry Lesser, LL.B., on his induction into the presidential chair, expressed the hope that national health organisations would coöperate in the treatment of rheumatism as seen in present-day industrial life. Approved societies, he remarked, have no power to make grants towards the cost of out-patient treatment of their members at hospitals; the Ministry of Health should allow the societies to assist their members by grants for hydrotherapeutic treatment, to count as additional benefit under the Insurance Acts. He quoted Sir George Newman's statement that the institutional treatment of arthritic patients was no longer merely an Utopian ideal; the concentration in an institution, properly equipped for research, of young patients with rheumatoid arthritis at an early stage could hardly fail to increase our present knowledge of the disease. Mr. Lesser set out the scheme promoted by the British Committee of the International Society of Medical Hydrology for the establishment of an experimental clinic for rheumatic diseases in London, and noted the proposal of the British Red Cross Society shortly to launch an appeal for £40,000 to found such a clinic, which if successful would be followed by the establishment of similar clinics in other parts of the country. Mr. Lesser based his remarks upon his recent tour of out-patient clinics for rheumatism in central Europe, where the field of investigation far exceeds anything yet attempted in this country. Although he failed to obtain statistics of the results achieved, he gained the impression that all the parties concerned—patients, physicians, employers, insurance officials—were agreed on the advantages to be derived from hydrotherapeutic treatment on those lines.

THE HARVEIAN CEREMONIES.

DURING the week of the Harveian Festival the President and Council of the Royal College of Physicians of London attended Bow Church, Cheapside, to hear the sermon preached annually under the Sadleir Trust, the preacher being the rector, the Rev. Gordon Ponsonby. The address formed a beautiful supplement to Sir William Hale-White's Harveian oration, which was printed in full in these columns last week, for he took as his theme the achievements of the Fellows of the College, who had died during the year, and whose lives had been dedicated to the progress of medicine along the many accessible paths made by Harvey's wisdom. In the evening a dinner was held within the College; the Speaker of the House of Commons (the Rt. Hon. J. H. Whitley), the President of the Royal Academy (Sir Frank Dicksee), the Secretary of State for Air (Sir Samuel Hoare), Prof. A. V. Hill (the recipient of the Baly medal), and other distinguished guests were present. Sir Samuel Hoare, in responding to the toast of the guests, made eloquent reference to the vast influence upon civilisation brought about by the strides in international communication, of which aerial transport was so notable an example.

THE annual dinner of the Royal Society of Medicine will be held at the Hotel Victoria, Northumberland-avenue, on Wednesday, Nov. 16th, at 7.30 for 8 P.M. Lord Darling will be the Society's guest of honour.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs.: S. F. Dudley to *President*, for R.N. College, Greenwich (Naval Medical School), as Professor of Clinical Pathology and as Specialist in Bacteriology; H. St. C. Colson to *Pembroke*, for R.N. Hospl., Chatham, and as Specialist in Bacteriology; G. F. Syms to *Victory*, for Portsmouth Dockyard; M. J. Aitken to *Calypso*; R. Lyon to *Berwick*; H. Wilks to *Cumberland* (on commg.); and F. J. D. Twigg to *President*, for three months' post-graduate course.

Surg. Lt.-Comdrs.: C. H. Savory to *Erebus*; R. P. Ninnis to *Vulcan*; T. N. D'Arcy to *Spenser*; and A. W. McRorie to *Ganges*, for R. N. Sick Quarters, Shotley.

Surg. Lts.: E. T. S. Rudd to *Columbine*, for R.N. Hospl., S. Queensferry; T. G. Davies to *Cumberland* (on commg.); C. G. Rippin to *Impregnable*; and G. Kirker to *Verbena* (on commg.).

ROYAL NAVAL VOLUNTEER RESERVE.

Prob. Surg. Lt. W. F. Lascelles to be Surg.

ROYAL ARMY MEDICAL CORPS.

Col. V. J. Crawford, late R.A.M.C., retires on retd. pay.

Lt.-Col. & Bt. Col. J. A. Hartigan, K.H.P., from R.A.M.C., to be Col.

Lt.-Col. W. M. H. Spiller, having attained the age fixed for compulsory retirement, retires on ret. pay.

Majs. P. C. T. Davy and G. A. D. Harvey to be Lt.-Cols.

The undermentioned Lts. (on prob.) from the secd. list, are restd. to the estabt.: F. McL. Richardson and J. W. Eames.

ARMY DENTAL CORPS.

Temp. Lt. J. B. Cowie, Dental Surg., Gen. List, to be Lt.

REGULAR ARMY RESERVE OF OFFICERS.

Lt.-Col. W. M. B. Sparkes, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Lt. A. H. MacC. Eaton to be Capt.

General Hospitals.—Maj. R. M. Handfield-Jones resigns his commn.

ROYAL AIR FORCE.

Flying Officer B. L. Edwards is granted a permanent commission in this rank.

Flying Officer H. Penman is promoted to the rank of Flight Lt.

INDIAN MEDICAL SERVICES.

Lt.-Col. A. C. MacGilchrist retires.

Capt. Abdul Hamid Shaikh to be Maj.

The undermentioned officers relinquish their temp. commns.: T./Lt. Tharmale Govinda Raghava Panikkar and T./Lt. Amar Nath Bajaj.

Lt.-Col. J. Cunningham, Directeur, Pasteur Institute of India, Kasauli, has been placed on special duty in connexion with the Seventh Congress of the Far Eastern Association of Tropical Medicine. The services of Lt.-Col. H. H. Thorburn, Agency Surgeon, have been placed at the disposal of the Government of India, Education Department. Maj. H. E. Murray, Second Resident Surgeon, Presidency General Hospital, Calcutta, has been appointed First Resident Surgeon of the Institution.

Army instructions issued in September notify the abolition of the Central Dermatological Laboratory at Poona from March 31st, 1928. In future its work will be done locally by the Principal District Laboratory in each command—viz., Rawalpindi, Quetta, Meerut, and Secunderabad.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCXLVII.

THE TREATMENT OF PERFORATING INJURIES OF THE EYE.

A PERFORATING injury of the eye must always be looked on as a serious surgical emergency and treated under the best conditions possible, since any temporising or inexpert care involves the risk not only of loss of the injured eye, but also of one of the most tragic of possibilities, the onset of sympathetic ophthalmia causing destruction of its fellow. The treatment of perforating injuries as usually adopted can only be dealt with by considering in the first place the diagnosis and classification of such injuries. The subject is large and only the broad principles which guide the procedure of the ophthalmic surgeon can be indicated, since in actual practice each case is different and must be judged on its merits.

Classification.

Cases of perforating injury fall into two groups: 1. Those in which the globe is perforated by a blunt or sharp instrument, but there is no retention of a foreign body within the eye. 2. Those in which a foreign body remains within the eye. Both these groups can be subdivided on an anatomical basis, according to the position of the wound and of the foreign body. The question of diagnosis arises when from the history it seems likely that a foreign body is present. The settling of this question is of the utmost importance in treatment and prognosis.

Diagnosis of Intra-ocular Foreign Body.

The presence of an intra-ocular foreign body may be extremely hard to detect. Occasionally it may be directly seen in the anterior chamber or with the ophthalmoscope, but this is rare. There are four further sources of evidence which can be tapped—namely, radiography, examination with the magnet, biomicroscopy with the slit-lamp, and the history of the accident.

Radiography.—If the foreign body is opaque to X rays it can be photographed, and by the application of Mackenzie Davidson's method can be accurately localised, with a margin of error of less than one millimetre. Fortunately, the majority of intra-ocular foreign bodies are metallic and can therefore be detected. Even lead glass fragments may be localised, but the lighter forms of glass are transparent to the rays.

Examination with the Magnet.—If the foreign body is magnetisable its presence can be detected by means of the Haab or Mellinger magnet. The patient usually feels pain in the eye when the current is switched on, if the foreign body is attracted, and in a number of cases—sometimes only after repeated switching on and off—it can be drawn forward into the anterior chamber and thence extracted.

Examination with the slit-lamp is of assistance in cases where the perforation is very small and there has been no loss of aqueous, or obvious hæmorrhage into the anterior chamber. By its means it is possible to make out with certainty whether a small deep injury to the cornea has actually perforated or not, and whether there has been the slightest trauma to the iris. In some cases the track of a minute foreign body through the lens can be detected before the lens fibres begin to swell up.

The *history* should be very carefully taken, as it will often throw light on the possibility of an intra-ocular foreign body. For example, in the case of an injury received while chipping stone with a hammer there is very likely to be a fragment of steel in the eye, while a blow from a large iron nail or bolt, though perforating, is not often accompanied by retention of any metal.

Treatment of Perforating Injury without Retention of a Foreign Body.

(*a*) Wounds involving the *cornea* only are the simplest to treat, since, if sterile, they heal spontaneously. The eye should be well washed out, atropine instilled, a bandage applied, and the patient kept at rest. A watch must be kept for the onset of sepsis, and if this supervenes the treatment of infected ulcer of the cornea must be carried out (see Modern Technique in Treatment, Corneal Ulceration, by P. G. Doyne).[1]

(*b*) Wounds involving the *iris and ciliary body* are more dangerous since the risk of sepsis or of sympathetic ophthalmia is much greater. The iris or ciliary body or both may be prolapsed through the wound and operative treatment then becomes imperative. A general anæsthetic is usually necessary, since it allows of more thorough examination and more efficient toilet of the wound. The patient is already in pain and any manipulation of the irritated iris may be felt even after the instillation of cocaine. The eye is well washed out with a solution of perchloride of mercury, 1 in 12,000. The lids are retracted, taking care that there is no pressure on the globe, and the wound is examined. Any prolapsed portion of uveal tissue is freed from the edges of the wound and cut off. On no account must any attempt be made to replace such tissue inside the eye since it is most certainly infected. In a certain number of cases there is already pus in the anterior chamber when the patient is first seen. Although the prognosis is then bad an attempt to save the eye may be made by washing out the anterior chamber with peroxide of hydrogen. In some cases this is successful. In cases not obviously infected, if the wound is large and involves the sclera or limbus, it may be sutured with fine silk, but this is seldom necessary. In most cases, however, it is as well to cover the wound in the sclera with a small flap of conjunctiva. Atropine is instilled freely.

In all cases the eye must be carefully watched for the following complications: (1) Sepsis, as evidenced by either an iritis which may yield to treatment or a panophthalmitis which will result in loss of the eye. (2) Formation of anterior synechiæ. These are very common and extremely difficult to avoid after excision of prolapsed iris through a corneal wound. They interfere considerably with the healing of the wound, keep up irritation in the eye, and are a source of danger. They are usually divided as soon as practicable. (3) Appearance of plastic irido-cyclitis with keratic precipitates (k.p.). This is a danger-signal and if it appears the eye must be excised, since the risk of sympathetic ophthalmitis is extremely great. If the lens is injured the risk of loss of the eye becomes greater, especially in children. The lens fibres swell up when brought in contact with the aqueous and press the iris forwards on to the cornea. The tension of the eye then rises and a curette evacuation of the softened lens is called for.

(*c*) When wounds involve the *sclera* and *vitreous* behind the ora serrata there is usually a wound of the lid as well, and the swelling resulting from this may be so great as to make examination of the eye very difficult. If so a general anæsthetic should be administered and a thorough exploration carried out. There will probably be much subconjunctival ecchymosis around the scleral wound, masking it. Vitreous, choroid, and retina may be seen protruding from it, in which case they should be cut off. Suture of the sclera and formation of a conjunctival flap is usually desirable.

Whenever an eye is so grossly injured that restoration of useful vision is improbable it should be excised, as the risk of retaining it outweighs the possible slight advantage.

[1] THE LANCET, July 16th, 1927, p. 133.

Treatment of Perforating Injury with Retention of a Foreign Body.

Once the diagnosis of intra-ocular foreign body has been made the question of its removal must be considered. If it is in the anterior chamber or if it is magnetisable and can be drawn forward attempts are made to remove it. The hand magnet is invaluable in these cases, being used to remove the foreign body through the wound of entry or through a corneal incision after it has been drawn into a favourable position by the larger magnet. It is of great importance that attempts at removal should be made as soon as possible after the injury, since the foreign body will very soon become involved in exudate and fibrous tissue from which it may be very difficult to extir it. If it is non-magnetisable or cannot be located its removal may be impossible. The prognosis is, however, much worsened by its retention. Very minute foreign bodies may become encapsuled and cause no trouble, but more often, though sight may be good at first, a slow degeneration of the eye sets in which finally renders it useless. In the case of retained iron the process is accompanied by solution of the iron and deposition of it in the uveal tract and in the lens (siderosis).

It is obvious that, apart from the question of the practicability of the removal of the foreign body, the most important point is the cleanliness or otherwise of the fragment. Pieces of metal are often hot when they fly into the eye and are more likely to be sterile than other substances, such as stone or wood splinters. These latter are very apt to give rise to suppuration, which may destroy the eye even though the foreign body has been removed. The prognosis is also worse if the lens has been injured. In such cases a second operation (curette evacuation) may be necessary to relieve the tension due to the swelling of the lens. Sometimes the foreign body is discharged with the lens matter at this operation.

Prophylaxis of Sympathetic Ophthalmia.

It is obvious that if an eye is so grossly injured that no restoration of function can be hoped for it should be immediately excised. When, however, attempts are made to save an injured eye a strict watch should be kept on it for many weeks. In the diagnosis of early sympathetic ophthalmia the slit-lamp is invaluable. It will reveal the earliest traces of k.p. in the exciting eye and will also render visible those fine changes in the anterior vitreous which precede the appearance of cyclitis in the sympathising eye. If regular examinations of both eyes are made the approaching danger may be seen and dealt with relatively earlier than was previously possible. It is also as well to do a differential blood count in suspicious cases, since a rise in the percentage of large mononuclear cells is found in most cases of sympathetic ophthalmia. The grosser signs—persistence of pain, lacrymation, and ciliary flush in the injured eye—are easily detectable, and if the eye has no useful vision it should, of course, be excised without waiting for the appearance of cyclitis.

Assistant Surgeon, Moorfields Eye Hospital;
Ophthalmic Surgeon, Elizabeth Garrett Anderson Hospital.

BIRMINGHAM HOSPITALS CONTRIBUTORY SCHEME.—This scheme will come into operation on Jan. 1st, 1928. The minimum contribution will be 2*d.* per week per person, and employers will be asked to pay at least 25 per cent. of the amount contributed by their employees. The hospitals will be open free to the very poor who are unable to join the scheme; persons of limited income will be eligible for free treatment if they belong to the scheme; contributors not considered eligible for free treatment may be called upon to make some additional payment. There will be a maintenance charge for non-contributory patients who can afford to pay 2*d.* per week, and hospital and convalescent home benefit will be extended to actual dependents of contributors. The Hospital Saturday Fund will be the principal branch industrial contributors' scheme for employers and employees.

Special Articles.

THE PANEL CONFERENCE.

THE annual conference of representatives of local medical and panel committees was held on Oct. 20th in the Great Hall of the British Medical Association's House, when Dr. E. K. LE FLEMING (Dorset) occupied the chair, and the proceedings opened with a tribute to the memory of Dr. T. Ridley Bailey. After some domestic business had been transacted, Dr. H. G. DAIN (Birmingham), Chairman of the Insurance Acts Committee (I.A.C.), moved that the conference approve the

Proposed Modifications in Disciplinary Procedure

upon which his committee had provisionally agreed with the Ministry of Health. He pointed out that there were two ways of dealing with the question of discipline: first, by agreement with the Ministry, and secondly, by the usual legal machinery. He understood that, if the profession were very strongly in favour of going to the courts to settle alleged breaches of contract, the Ministry would not offer any great objection. That would get rid of the final decision of the Ministry without appeal—the great bogy of the profession. But it would also mean the publicity of the courts in all cases. If the profession preferred the method of disciplinary machinery inside the service, then—said the Minister (and the speaker sympathised with him)—they ought to accept the Minister's final decision. In any case the Minister was unwilling to accept the liability of being summoned to appear in court for any decision he made (a very reasonable refusal, Dr. Dain remarked). He could not prevent an appeal on the ground of irregularity or an action ultra vires, but he was not prepared to consider any appeal on the merits of the case.

In the view of the I.A.C., Dr. Dain continued, the chief disadvantage of the existing machinery was the presence of a certain gap, which they had not expected when it was first set up—an interval during which they had no knowledge of the proceedings. They had provided that cases should be heard in a certain way with certain methods of appeal, and that in the end the Minister should have the decision; but they did not know what happened between the hearing of the case by the Medical Service Subcommittee or the Committee of Inquiry and the Minister's decision. They were not aware how the Minister made up his mind, and had no control over nor knowledge of the stages between these two events. When the scheme was initiated there had been no Ministry of Health; there had been National Insurance Commissioners, who would, the Committee had been assured, themselves deal with the reports in disciplinary cases; this method the Committee had been prepared to accept and would be prepared to continue. The head of the department, however, had so many duties that he had to delegate some of them, and the Committee thought that that was the chief disadvantage of the present scheme. He hoped that the conference would find that the suggestion he was about to put before them would bridge over that gap. It provided for the association of the panel practitioner with the machinery from the beginning until the final recommendation upon which the Minister acted. The duty of the Committee's representatives would be to see that fair play was given at every stage of the proceedings. The new scheme would provide for what Mr. Lloyd George called "the judgment of the doctor by his peers." At no stage would a civil servant alone be empowered to deal with a case.

Time Limit for Complaints.

Dr. Dain went on to outline the existing procedure step by step, and to explain the effect of the suggested modifications. To begin with, he said, the limit fixed

by the regulations on the time which might elapse between the alleged breach of contract and the lodging of a complaint about it was in certain areas almost entirely disregarded. That meant that an insurance committee officer who was hostile to the medical point of view or the medical service might find some reason for having the case heard at almost any date. If the conference accepted the report he laid before them, it would become an established fact that the Medical Service Subcommittee might investigate any complaint made between six and eight weeks after the act, but that the consent of the Minister would be necessary if the interval were longer than two months, and the Subcommittee would have to satisfy him that there existed reasonable grounds for the delay. The doctor would have an opportunity of objecting to the extension, and would be in the same position relative to the Minister as the Medical Service Subcommittee. That, in Dr. Dain's opinion, adequately safeguarded the position.

Again, in some areas, complaints against doctors had been couched in very vague terms, and fresh causes of complaint had been admitted during the hearing; the doctor had accepted the position. The Ministry had agreed to inform insurance committees that complaints should be as specific as possible. While the conference might be disappointed that this was not made a definite regulation, they would see the inadvisability of pressing to have it made absolute, which would mean in most cases that the clerk to the insurance committee would have an interview with the patient or society complaining in order to find out exactly what the complaint was. This would put him in a position to hear the case with nobody there and to ask any questions he wished, and this might result in much more serious charges being made than had at first been intended.

Position of the Clerk at the Hearing.

There were, unfortunately, clerks who considered it their business to act as prosecuting counsel. This was, of course, an entirely irregular procedure, and could only happen with the consent of the doctors sitting on the committee. The doctors were there to see fair play and if they did not prevent this no regulations could. It was for the panel practitioners to replace such members of the committee with others who had a better appreciation of their duties. There were circumstances in which the clerk might consider himself entitled to act in this way; for instance, when the complaint was made by the Medical Benefit Subcommittee or the Insurance Committee itself. The Ministry had agreed that insurance committees should be told that this procedure was unsatisfactory and that the clerk should only act in the manner prescribed.

Other areas had submitted reports which had never really been properly considered by the Medical Service Subcommittee. This again could only happen with the consent of the Subcommittee. In his own area all reports were submitted to the members present, and if a majority disapproved they were reconsidered. The Minister agreed that the best shorthand notes available should be taken, and that the report should be approved by the Subcommittee.

Powers of Insurance Committees.

Under the regulations the Insurance Committee might do one of four things on the report of the Medical Service Subcommittee: they might remove the patient, limit the list, recommend deduction of money, or advise the deletion of the doctor's name from the panel. The new scheme proposed to give them the additional power of censuring the doctor. Whereas now they often felt themselves bound to make representations, if they could warn, caution, or censure a doctor they might not need to recommend in many cases that money should be withheld.

When the Insurance Committee had considered a case and made a recommendation, the papers went to the Ministry, and the respondent was advised of the finding, furnished with the report of the Medical Service Subcommittee, and told that he might appeal, if he wished, within a given time. Up to now any appeal had been heard by one or two officers of the Ministry; the Minister had now agreed that in future a doctor nominated by the I.A.C. should be associated with those officers to hear the appeal. Dr. Dain reminded his hearers that, like all appeals in law, this appeal was a reconsideration of the evidence already heard and not a rehearing. If, on the other hand, the respondent did not appeal, he was told at the end of the month that the Minister was considering the report of the committees and perhaps contemplating a money deduction. He might then make a representation in writing or orally; if he chose the latter, officers of the Ministry were sent down to his area. The I.A.C. had now arranged that a doctor nominated by them should be present at that hearing.

New Joint Advisory Committee.

The Ministry, having all the reports in hand, now considered what should be done and what the final decision should be. This was where the new body came into operation. All cases at issue would in future be referred to what was called a Joint Advisory Committee, which would consist of the chief and two other medical officers of the Ministry and three doctors chosen from a panel which the I.A.C. would themselves nominate. That body would consider the reports of the Medical Service Subcommittee and the Insurance Committee and the respondent's oral representation, or the findings of the court of appeal, and would advise the Minister as to the action he should take. In promulgating his decision he was not, of course, compelled to accept the findings of this body, but as a matter of practice and business he was inevitably bound to accept them. If he did not, then the scheme had failed, and it would be necessary to find some other method of dealing with the disciplinary machinery.

Other cases were heard by a Committee of Inquiry, which sometimes recommended that a doctor should be removed from the panel. It had been said that the functions of that committee were improperly curtailed and that it had no power to hear certain evidence. That was untrue, and the committee could hear any evidence it saw fit to entertain. The admission of improper evidence was ground for appeal from this court as from any other, but it was presided over by a barrister who was always, in Dr. Dain's experience, very careful. The Committee of Inquiry advised the Minister of the facts found and the inferences to be drawn from them, but made no specific recommendation about the penalty. The only punishment provided was removal from the panel, but there had been cases in which the evidence had not been conclusive enough to warrant removal, although the Minister had withheld the grant. It had been decided last year that the Minister should not inflict a lesser penalty without a rehearing of the case before the Advisory Committee. The Minister would use the Advisory Committee for the major question as well. As a matter of experience, the I.A.C. was not aware of any case in which the Minister had ever removed a doctor from the panel against the weight of evidence.

These, then, said Dr. Dain, were the chief alterations which the I.A.C asked the conference to approve in the disciplinary machinery. If they approved of them, his committee considered that they should definitely undertake to forego, for a period of years, any right to modify them or to appeal to the courts. The scheme had its disadvantages, but seemed fair and just from beginning to end, and was worth a trial. If it worked fairly, they would be better off both in the public estimation and financially.

Minor modifications were the limitation of the Minister's power of initiating complaints to cases of alleged failure to keep adequate medical records, to return Form R.2, and to report on tuberculosis cases. He could now order an inquiry without receiving a

representation only when a doctor had already been convicted of a felony.

The work of the new committee would be confidential, but it would be the duty of its members to see that nothing unfair was done, and to refuse to admit unfair evidence. If things happened of which they disapproved, their method would be to come back to the Insurance Acts Committee and resign. That committee would then have to admit that the scheme was unsuccessful. Until that happened, however, provided that they selected the proper representatives and the committee functioned properly, the result would be a machinery free from any possibility of abuse and satisfactory to the men working under the National Insurance scheme.

Discussion.

The proposed scheme aroused considerable discussion, but none of the amending motions was carried, and many of them were withdrawn after the conference had heard the explanations of representatives of the committee. The recommendation was finally passed as proposed. Criticisms showed considerable distrust of a scheme which did not allow for a final appeal to the courts, and motions to demand this were brought forward by Wolverhampton and Cheshire.—Dr. L. J. PICTON (Cheshire) observed that panel doctors were medical citizens and not State servants and that their contracts were not different from that of a builder with a county council; it was essential to maintain this. In arbitration arrangements there was always a clause admitting of appeal, and it was reasonable to regard the whole disciplinary machinery in this case as an arbitration scheme. The right of appeal would be very seldom used but would be the greatest possible safeguard against abuses.—Dr. A. FOSTER (Worcester) pointed out that the judges were continually complaining of the increasing power of Government Departments, and Dr. DAIN agreed that it would be very difficult to secure the appeal clause until the judges had succeeded in strengthening their position. It would mean a hard fight, and he did not want to fight for something that might prove unnecessary. Great improvement had been obtained through negotiation, and he urged the meeting to give the scheme a fair trial without committing itself on the subject of the appeal. Cheshire and Wolverhampton thereupon withdrew their motions, but Dr. GORDON WARD put the motion of Kent—

That the proposed disciplinary procedure is open to the objection that: (*a*) it leaves the decision as to guilt and penalty in inquiry cases with persons who have not heard the evidence; (*b*) it permits evidence to be brought against a practitioner or an insurance committee of which neither party is made aware; and (*c*) it proposes that this state of affairs shall remain unquestioned for several years.

He maintained that the I.A.C. was not strong enough; the Advisory Committee was not a judicial body and the Minister was not forced to choose its members in rotation; he would soon get on it those who were complaisant. Dr. DAIN challenged the accuracy of the Kent statements; guilt was decided in every case by the Medical Service Subcommittee, and the whole object of the Advisory Committee was to prevent the production of evidence of which the doctor or the insurance committee were unaware. A term of three years was not long enough to do any harm. Dr. H. B. BRACKENBURY (Middlesex) emphasised the advantages secured, particularly the bridging of the "dark gap" and the acquisition of a perfectly professional tribunal to decide questions of medical procedure. The Kent motion was lost. London wanted the panel for the Advisory Committee to be either nominated or approved annually by the Panel Conference, but Dr. DAIN persuaded the meeting not to adopt this cumbersome procedure and to leave the matter in the hands of the I.A.C.

Dr. J. HOLMES, proposing a motion from Bury, that all evidence against a medical man should be given on oath, emphasised the gravity of this for the doctor. Dr. DAIN replied that the evidence was given on oath in Scotland, but it did not seem feasible to get the same procedure in this country. He was not satisfied that the oath would materially alter the witnesses' statements. The Bury motion was withdrawn on his promising to inquire into the possibilities.

Dr. H. J. CARDALE (London) then proposed three motions by London. One opposed the suggestion that a "plea in extenuation" might be made at the end of the hearing of a complaint; the second maintained that any additional issue raised at a hearing should be made the subject of a fresh charge, and the third wished to limit the functions of clerks in all cases investigated by the Medical Service Subcommittee. Dr. CARDALE pointed out the absurdity and prejudicial effect of a "plea of extenuation" put in by a solicitor before his client had been found guilty, and said that the doctor was often the worst judge of what was best for his case. Dr. DAIN said that many doctors would prefer to get it all over at one hearing and on balance they did better as things were. The Ministry would not object to a second hearing if there had been or would be prejudice. The doctor could always demand an adjournment. He reiterated his remark that the procedure of any clerk must depend on the men constituting the committee; it was impossible to provide for rabbits on a committee by rules and regulations.

Scotland.

Scotland, said Dr. Dain, did not come under this scheme, but had agreed to it in principle, except that it was not proposed to press for limitation of the clerk's activities.

National Insurance Defence Trust.

The proposal of the trustees of the Defence Trust to subscribe £1000 to the Representation-in-Parliament Fund of the British Medical Association aroused much opposition. Kent, Stockport, and West Ham sent up motions condemning it as undesirable or illegal, and the West Ham motion, expressing disapproval of the action, was passed by 71 votes to 66. Dr. H. S. BEADLES (West Ham), Dr. GORDON WARD, Mr. H. D. POLLARD (Bedfordshire), and Dr. D. O. TWINING (Devon) supported it. Dr. DAIN said that legal advice had been taken and both he and Sir ROBERT BOLAM urged the conference to take the large view of medical organisation. The best way to influence legislation, said Sir ROBERT BOLAM, was by quiet talks to officials before proposals had gone too far, and it was much better to prevent trouble than to wait until it came. It would pay them over and over again if £2000 or £3000 would keep two or three doctors sitting in Parliament. Dr. J. A. PRIDHAM (Dorset) illustrated this from his own experience of county council work, and Dr. BRACKENBURY pointed out that the proposal was not to hand over the sum to another fund but to use it for supporting approved candidates on the trustees' own conditions. It would be of the greatest importance to have suitable candidates in Parliament when the National Insurance Act came to be extended.

Collection of Statistics.

Kent and Gateshead urged the publication of statistics and the establishment of a statistical bureau. Dr. DAIN replied that a bureau would be established as soon as local committees provided it with statistics to work on. Meanwhile, figures were being collected as far as possible and were available for any area which required them. He deprecated their publication and the motions were lost.

Change of Doctor.

Dundee deprecated the new 14-day scheme for change of doctor and preferred the old six months' period. Dr. DAIN explained that the I.A.C. had had to deal with a very urgent matter and had been unable to consult the conference before acting. He thought the new scheme would discourage canvassing as well as preventing patients from getting certificates too easily. The recommendations of the Committee were

finally carried as put, with the exception of an amendment by Hertfordshire, modified by London, and accepted by Dr. Dain. This read :—

That when an insured person asks the insurance committee to transfer him from one local practitioner to another and gives some complaint against the doctor as a cause for the transfer, the committee shall arrange the transfer and shall inform the insured person that if he wishes to persist in the complaint it must be made in a separate letter.

Accidents, Mileage, and Ultra-violet Treatment.

Buckinghamshire and Northamptonshire brought forward, but failed to carry, motions asking for a special payments fund for accident cases, and for payment for emergency treatment from the Central or Area Fund. Hampshire was dissatisfied that no increase had been made in the Mileage Fund for 1927, although the statistics showed an increase of 25 per cent. on the miles travelled. Dr. DAIN said that it would be unwise to reopen the question. Cost of travel had decreased, and on the whole rural practitioners were not dissatisfied.

The Committee's report had expressed the opinion that ultra-violet ray treatment was not necessarily a specialist service, and that local committees must deal with it as cases arose. Somerset wished to refer this back, and motions from Gateshead and Dundee maintained respectively that it was a specialist treatment, and that it was not part of the duty of the ordinary practitioner. Smethwick wished to arrange some special fee for this work. Dr. DAIN saw no way of making a fair arrangement under existing procedure, but accepted Somerset's amendment.

Ophthalmic and Dental Benefit, and Benefit for the Aged.

Dundee, Bury, Liverpool, and Dorset asked for special arrangements for the cards of insured persons over 65, as old-age pensioners at present disappeared from the panel lists. Dr. DAIN agreed to discuss with the Ministry the best way of dealing with the difficulty of the aged insured person, and it was agreed that patients should have free choice of ophthalmic and dental surgeon.

The Chemists' New Agreement with the Ministry.

This year the chemists have agreed to take over the whole Drug Fund, and take the risk of profit or loss on the transaction. No specific sum was mentioned, though a minimum was fixed and an estimate made. This arrangement called forth motions of protest from Gateshead, Kent, Northumberland, and Lancashire. Dr. LE FLEMING pointed out that it was a *fait accompli*, made without the consent of the doctors ; he asked the conference seriously to consider whether any good purpose would be served by anticipating at this stage trouble arising between doctors and chemists or an inferior dispensing service resulting from the new arrangement. Dr. BRACKENBURY appealed to the conference not to press their censure ; the I.A.C. had already informed the Government that it considered the arrangement contrary to public policy, and there was no good in making extra difficulty. Dr. DAIN assured Northumberland that the position of the dispensing rural practitioner would not be altered and that his fees would be a first charge. Dr. GORDON WARD insisted on the importance of a protest, however, and carried the Kent motion as follows :—

That with regard to the proposals of the Ministry of Health relating to insurance prescribing, the proposed arrangement which would make it possible and financially profitable for chemists to limit the quality and quantity of medicines prescribed for insured persons, is contrary to public policy.

He failed, however, to carry a motion calling attention to grave deficiencies in the pharmaceutical service, such as failure to dispense promptly and to make provision for emergency prescriptions. Dr. DAIN said that a subcommittee had been set up which would go into complaints of this nature.

Coventry carried a motion designed to check excessive prescribing, and help doctors to know how they compared with the average, by asking that the data supplied by pricing bureaus, &c., to pharmaceutical committees should also be supplied to local panel committees.

A National Formulary.

Opinions were divided on the desirability of a National Formulary, urged by West Suffolk. Some thought that it would give the impression that panel patients were prescribed for in a set and specially cheap manner ; others thought the evils of stock mixtures were exaggerated. Dr. DAIN characterised the opposition as theoretical and very unpractical, and the motion was carried.

While agreeing with Walsall that private referees appointed by approved societies were undesirable, the Chairman asked what steps the I.A.C. could take in the matter, and nobody was able to suggest any. A motion by Gateshead deprecating any referees other than the regional medical staff was carried.

A motion by Drs. H. J. CARDALE and C. L. BATTESON (London) approving the principle of research by panel practitioners was carried, but the conference decided to pass to the next business when asked to agree that the doctors should be paid for such work. Dr. E. A. GREGG (London) pointed out the special value of research of this kind in view of the regularity and continuity of observation, and the stereotyped records at the disposal of insurance practitioners.

The Dinner.

The annual dinner was held at the Holborn Restaurant in the evening, under the chairmanship of Dr. LE FLEMING, and was an informal affair with a short toast list.

MEDICAL SERVICE IN THE MERCANTILE MARINE.

NOT long ago the value of seeking a temporary billet with one of the steamship companies would be put before newly qualified men by the teachers at the medical schools, who would detail the advantages to young men of seeing the world in this way. These advantages may still be obtained in the employment of some of the companies, but others, and mostly the more important ones, have a medical service, which though it is not of the long employment type prevailing in the Fighting Services, still does not offer temporary engagements for brief periods. But this statement requires some qualification to make it cover all the circumstances, so that every candidate for medical employment with the mercantile marine must address the company selected and obtain a statement of the terms offered. Although there is no uniform pattern the following will give a composite view of the situation on British lines, and it may be added that much the same conditions prevail in the best foreign lines, but foreign nationality is then generally made a condition.

On all the British steamship lines the medical officers must be of British or colonial birth and their names must be on the Medical Register. The age-limits for entrance and for the period of service vary considerably. The posts are frequently open to the middle-aged, and medical men may expect appointments in some quarters between the ages of 30 and 50, though one company gives the top limit for entrance at 45 and another at 40. One of the largest companies states that it does not consider applicants under 25, though few men apply for the posts at so early an age, particularly as throughout the service stress is laid upon the importance attached to experience after qualification. Certain of the companies require a health certificate with the application, but in most cases the chief medical officer or medical inspector will interview the candidate on behalf of the company. In the matter of testimonials and references the procedure is fairly uniform. References are required, usually two, and several companies lay stress on the fact that one of these should be from a non-professional source

vidence of previous experience must be furnished, nd the holding of house appointments or other esponsible billets counts in the candidate's favour.

The tenure of the appointments varies, and therefore o scale of pay can be given in detail. Some companies arry a permanent staff, but in others, equally well nown, the actual appointment is from year to year for one voyage, the contract being renewed as long s it is mutually satisfactory. That such appointents amount to a permanency is noted by the .M.O. of two of the most important companies, who ate that they have officers who have served the ompany in this manner for 20 consecutive years. he scale of pay is fairly alike in all the companies. s a rule it is £25 per month, rising by yearly crements of £1 monthly to £35, and in one case to 40 per month; but the exact facts will, of course, e ascertained by every candidate on seeking employent. Where long tenure introduces the question of ompulsory retirement the age settled is from 60 to 3, and pensions or gratuities are at the discretion of he managements. Alterations in the conditions of rvice on some of the companies are, however, ntemplated.

In addition to salary the medical officer is entitled make private charges for attendance upon ssengers, and the arrangements here differ with fferent companies and with the class of steamer, but rtain common principles prevail. It is usual for e company to fix the scale of fees to be charged by edical officers to passengers. In some cases all illsses and accidents to passengers can be charged for less that illness or accident can be reasonably held be due to the fault or negligence of the company. t the regulations of some companies show that es can only be received in respect of illnesses which not have their origin on board, and there is somenes an embargo upon the doctor paying more than o visits per diem to a patient in a private capacity ve with the knowledge of the captain. This proviso we believe, a remnant of old prejudices; it would ver be allowed to interfere with the discretion of the edical officer. Throughout all the lines fees for st-class passengers are higher than for second-class ssengers, and in some cases third-class passengers e attended by the medical officer gratuitously in e same way that he attends the ship's crew.

The arrangements for leave do not differ much on e different lines. The medical officer can expect ree weeks' holiday yearly on full pay and some of e lines offer to allow this to accumulate for three ars. In some companies the period may not be entioned, as the duration of leave corresponds with ay in a home port. One company offers a month's liday on full pay every year, and another, while ying the medical officer for periods when off duty, cause the ship is in port or being overhauled, grants so leave on full pay for post-graduate study. One mpany offers a subsistence allowance in addition to ll pay.

The medical equipment on board ship will, of urse, differ with the size of the ship and the length the voyage. The larger ships may carry two rgeons, two sisters, and one or two dispensers. On e smaller ships the doctor may have to work with hospital attendant only, whose duty it may be to ep the dispensary in order, the responsibility of spensing remaining with the doctor. On all the es the medical officer pays for his uniform and metimes for a named list of instruments, while in hers the company is at the latter expense. Drugs e invariably found by the company.

Other points to be noted are that the foreign eamers using British ports are manned by foreign ctors in ordinary circumstances, and that none of e companies extends facilities to the medical officer be accompanied by his wife.

Such is a sketch of a career which, while it possesses general pattern, is clearly open to individual variaons in many of which the medical practitioner may d attractions.

MEDICINE AND THE LAW.

Coroner and Jury: Inquisition Quashed for Irregularity.

ALTHOUGH a coroner is allowed an ample latitude in the conduct of proceedings at an inquest, there are yet a few irregularities of which superior courts will take notice. Thus a Divisional Court had occasion on Oct. 13th to quash a coroner's inquisition and to direct a fresh inquest on the ground that the coroner had entered the jury's retiring-room. The general grounds for quashing a coroner's inquisition are broadly two—some irregularity in the inquisition and verdict or some irregularity on the part of the coroner or jury. As instances of the former class may be mentioned cases where the facts set forth in the inquisition did not warrant the jury's finding, or where the finding was uncertain, or where the word "feloniously" was omitted from a verdict of manslaughter. Instances of the latter class are cases of actual misconduct—as where in 1701 a coroner took some of the jurymen off the inquest after they had been sworn in order that he might influence the verdict—or cases of mere technical irregularity like that of the case which occurred just before the operation of the recent Coroners (Amendment) Act where an inquest was held without view of the body.

The recent case in which the Divisional Court interfered was an inquest held in the Thirsk Division of the North Riding of Yorkshire upon the death of Mr. Walter Tindall, a veterinary surgeon of Stillington, who was knocked down and killed by a motor-car. The coroner's jury last August returned a verdict of "Accidental Death" but added a rider—as juries love to do—saying that they thought there had been a certain amount of negligence and that they desired to censure severely the driver of the motor-car. The motorist, dissatisfied with this finding, got a rule *nisi* for *certiorari* to bring up and quash the inquisition on the twofold ground, first, that the coroner was present in the jury's retiring-room for a quarter of an hour while they were considering their verdict, and took the verdict in private; and, secondly, that the verdict and rider were contradictory. The decision turned upon the first of these grounds. There were two Irish cases in point. In the Ballyragget case (1883) some of the jury had unnecessarily absented themselves from the inquest; they went out into the public streets, and before they delivered their verdict the coroner spent some time with them in private. This was held fatal to the inquisition and there was a similar consequence to the Mitchelstown inquisition (1888) where a coroner not only spent an hour in the jury's room after the jurors had retired to consult upon their verdict but had also committed some irregularity by interfering in the summoning of the jury. In the Mitchelstown case the coroner was told that the jury had agreed, and he thereupon visited them before the verdict was declared; he took the verdict in private and drew up the inquisition before returning into court. These Irish decisions were held to apply to the recent Yorkshire case. No comment was made by the Lord Chief Justice on what the coroner for the Thirsk Division had either said or done. It was not suggested, said Lord Hewart, that the coroner was doing anything other than helping the jury in the discharge of its duty, but, doing so in that place (the jury's retiring-room), he was guilty of misconduct and the inquisition must be quashed. A fresh inquest was ordered to be held before the coroner for the Pickering Division of the North Riding. On behalf of the Thirsk coroner, and in support of the challenged inquisition, it was argued that the real attack was not upon the coroner's presence in the jury's room but upon the jury's rider. It was suggested that the court had power to strike out the rider, in which event the verdict would be unobjectionable; it was also pointed out that the verdict and rider were not really inconsistent; they simply meant that there was carelessness but not criminal negligence. However, as already stated,

the Divisional Court did not pass any opinion upon this aspect of the inquest, there being sufficient ground for upsetting the inquisition upon the irregularity of the coroner's visit to the jury.

Cost of X Ray Photograph: a Gap in the Insurance System.

The benevolence of the pious founders of charitable institutions in England has resulted in traditional acceptance of the fact that the law gives no recognition to the moral duty of paying for services rendered by a hospital. The increasing perils of motor traffic are introducing more and more people to a personal knowledge of the value of our hospital system as well as to a realisation of the wisdom of insurance against accident. Men and women who find themselves under treatment in hospital as the result of injuries received in accidents naturally desire, out of ordinary decent feeling, to make such financial return to the hospital as they can reasonably afford. But they learn to their surprise that their insurance policies do not entitle them to a refund of any hospital fees which they may have paid. The insurance companies repudiate liability on the ground that there is no legal compulsion to make such payments for hospital treatment. Fresh legislation would be necessary to alter the position, unless the companies can be induced to take a more generous view.

A correspondent, whose letter is published in the *Times* of Oct. 21st, gives a fresh illustration of this gap in our insurance system. A chauffeur injured his foot while on duty and the doctor deemed it necessary to have an X ray photograph taken. Subsequently the chauffeur received an account from the hospital for one guinea. He applied to his approved society for assistance towards paying the account, but was informed that it was an additional benefit not covered by their scheme and that, therefore, no grant could be given. The chauffeur's employer, being insured under an employer's liability policy, made a claim thereunder for the cost of the X ray photograph. The underwriters replied that it was a contingency not covered by the policy, since there was no legal liability upon the employer to pay the hospital. Thus either the chauffeur (who cannot well afford it) or the employer (who is in no way liable) must pay out of his own pocket for an item of treatment which one of the two systems of insurance, national or private, should certainly have covered. It is just conceivable that a hospital would be entitled to recover a fee for a specialised service such as the taking of an X ray photograph under the ordinary law of contract, though no fee could be recovered for treatment. But, as is well known, hospitals have to consider whether the privilege of being a plaintiff in certain cases is worth the risk of being a defendant in others.

Osteopath's Unsuccessful Claim for Fees.

The recent action in the Bloomsbury County Court has failed to settle the vexed question whether an osteopath can recover in a court of law the fees which he claims for his professional services. The county court judge decided the case upon issues of fact. In effect he held that the plaintiff's services were worthless; the fees had not been earned, so there was no question whether they could legally be recovered. From this finding of fact no appeal can presumably be made. The question of law thus stands where it did—in a condition of some uncertainty. The action began with the claim of an osteopath for the sum of £30 9*s*. for professional services rendered to the defendant's wife. The plaintiff, who described himself as a doctor of osteopathy, examined and treated the defendant's wife and made charges on the scale of 3 guineas for a consultation and 2 guineas for each single visit, including treatment. The deputy county court judge non-suited the plaintiff. He held that the claim was barred by Section 32 of the Medical Act of 1858, which declares that "no person shall be entitled to recover any charge in any court of law for any medical or surgical advice, attendance, or for the performance of any operation . . . unless he shall prove upon the trial that he is registered under thi Act." The Divisional Court, however, allowed th plaintiff's appeal on the ground that there is a distinc tion between advice and treatment, and that th plaintiff might be able to recover fees for the on though debarred from recovering fees for the othe As the judge in the court below had not provided an material for deciding whether the amount claime could be split up and a distinction made betwee charges for treatment and charges for advice, th Divisional Court sent the case back to the count court for a new trial. Legal opinion is by no mean unanimous that the Divisional Court was righ Advice, say the critics, cannot be severed from treat ment; the patient takes the treatment because of th advice. If a contract contains legal and illega elements and the legal cannot be severed from th illegal, the whole contract ought to be held voi The Divisional Court was following the older case o Hall *v.* Trotter, but in Hall *v.* Trotter the element o advice was apparently absent. Be that as it may the county court judge, to whom the case wa remitted, found himself able to dispose of it withou considering these legal niceties. His honour Judg Hill Kelly stated that he was satisfied that the treat ment given by the plaintiff to his patient could not hav achieved any beneficial results; he came to the cor clusion that the services rendered were wholly useles and he gave judgment for the defendant with costs.

The plaintiff, in giving evidence, described a osteopath as one who by moving bones relieve suffering; in fact, in cross-examination he agreed tha osteopathic treatment was worthless if the sufferin cannot be relieved by moving bones. The patien he said, came to him in March, 1926, after havin benefited by osteopathic treatment at Eastbourn He examined her and found certain bones were not i their proper position. She complained of a pain i her neck, that her tongue was "glued to her mouth in the morning, and that her eyes were very tende She suffered from general debility. He gave trea ment to relieve these conditions and he said that, the patient had been more regular in attending f treatment, she would have been cured of the trouble of which she complained. Sir Herbert Waterhous a witness for the defendant, said that the movemen of bones would not have removed the pain in th eyes of which the patient complained. Another wel known surgeon, Mr. Frank Romer, said that the bon stated to have been moved by osteopaths could n be moved. Dr. J. C. Keats, of High-street, Wanstea who had been the patient's regular medical attendan spoke of the results of his examination of her ar expressed the opinion that the osteopathic treatmen she had been receiving was wholly useless and th she derived no benefit therefrom. This opinion th learned judge adopted. The case indicates that in particular set of conditions a particular osteopat made a claim which could not be substantiate possibly it indicates nothing more. The plaint was careful to distinguish the moving of bones b osteopaths from the mere movement of muscles b massage. This was an opportunity to obtain a judici ruling whether the moving of bones by an unregistere osteopath is or is not an "operation" within th meaning of the Medical Act already quoted. Bu unfortunately the point was not decided.

THIRTY YEARS OF KING EDWARD'S FUND.—Th Prince of Wales was the principal guest at a lunche given at the Mansion House by the Lord Mayor, in co memoration of the thirtieth anniversary of the establis ment of King Edward's Hospital Fund for London, and t work of the League of Mercy. Recalling the achievemer of the Fund, the Prince said that in the last three years had helped to add 1100 beds to the metropolitan hospita and reminded his hearers that one of its committees is present inquiring into the serious question of the provisi of beds for paying patients. In the year of the Fund's ince tion the expenditure in hospitals in London was £700,00 it is now £3,000,000, and the annual distribution has ris from £32,000 to £245,000. The League of Mercy has giv the Fund nearly £400,000, and has, in addition, distribut more than £87,000 to local hospitals outside London.

THE NEW BIOCHEMISTRY BUILDINGS AT OXFORD.

A RECENT gift of £75,000 made by the Rockefeller Foundation for a new department of biochemistry at Oxford solved two problems that had been exercising the minds of those who direct research at the University. One of these was the need of additional accommodation for the Department of Physiology; the other was the claim of biochemistry to adequate recognition in the home of some of its most eminent pioneers. The first chair of biochemistry was endowed by Mr. Whitley in 1920 and was occupied by Dr. Benjamin Moore until his death in 1922. He was succeeded by Dr. R. A. Peters, who has had the good fortune to watch the inception and rapid growth of the new building for which the plans were prepared and the site cleared as recently as 1924. In order to maintain organic contact between the departments of physiology and biochemistry the two sections have in common a large lecture room and a library. The former was actually in use in October, 1925; classes were transferred to the new laboratories in October, 1926, and the move was completed at the end of the year. The school was formally opened on Oct. 21st by Viscount Cave, Chancellor of the University.

THE NEW INSTITUTE OF BIOCHEMISTRY.

In order that the windows might be as wide as possible the narrow spaces between have been treated as pilasters in a classical "order" and the outer walls are faced in aluminous cement. The main walls are of brick and the floors and roofs of reinforced concrete, supported on steel stanchions. Internal partitions are of light but rigid breeze concrete, and are so constructed that they can be moved easily if at some future date rearrangement of the rooms should be found desirable. All the fittings, too, are as movable as possible; drains are regularly spaced, and gas, water, and electric power lavishly supplied. The object is to allow the building to "find itself" in Kipling's phrase, as the teaching and research work carried out in it develops. All the rooms have wooden slats on the walls and beams on the ceilings for the suspension of apparatus, and many are ventilated by fans. There are two electric lifts, and the main staircase, like the outer doors, is of English oak.

On the ground floor is the main lecture theatre, common to the two departments, with a separate preparation room for each. On either side of the passage to the hall lie the unpacking and centrifuge rooms, the refrigerators, lavatories, and stores. Also on this floor are dark rooms for photography and physico-chemical research, a workshop and a room for keeping rats. There are also research rooms.

The two classrooms are on the first floor and are 16 ft. high; they are separated by glass partitions, so that they can be used as one room or two. Thus, if necessary, 100 students could be taught at a time. Leading out of them are preparation and dark rooms and the main balance room. The new library is also on this floor, which like the ground floor, communicates directly with the physiology department. Between first and second floors is a mezzanine, occupying the space left by the great height of the class rooms. Here is a rest room, a room for constant-temperature work insulated by a cork lining, a research room, and the indoor animal house. The last has an asphalt floor and enamelled walls.

The second floor is entirely given over to research work, and will accommodate 20 workers. Besides the various small laboratories it is provided with an aquarium room, an operating theatre, an animal bathroom, a sterilising room, and a flat roof with a small open-air laboratory. The aquarium has been modelled upon that at the Molteno Institute, Cambridge, and its large tank is made of Cambrian slate. Water for the tank is collected from a specially tiled part of the roof and carried through vulcanite fittings.

It will be seen that the new institute is not unworthy of its place in the University. Where Boyle, Hooke, Lower, Mayow, Willis, and Wren worked, but left no school behind them, J. S. Haldane, F. Gotch, and C. S. Sherrington have carried on the tradition of biochemical research under the roof of the physiology

building. Their successors will now have circumstances in their favour, and the authorities feel that the most urgent need at present is for studentships to enable men to stay on for one or two years to be trained in research work. An appeal is made for help in this direction and also for a stable endowment for the research library, at present supported by funds from each of the departments.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Dentists Bill.

THE Dentists Bill for the Irish Free State was introduced to the Dail last week for the third time. A warm debate, in which most of the medical Members took part, centred round the clause which gives protection to the dental profession. The clause lays down that it shall not be lawful for any person, on or after the date of the passing of this Act, to practise, or hold himself out, whether directly or by implication, as practising, or being prepared to practise, dentistry or dental surgery, unless such person is a registered dentist. A subsection allows the performance by a registered medical practitioner of any surgical operation in connexion with the tissues of the mouth or jaws, or the giving by a registered medical practitioner of any dental treatment, advice, or attendance in urgent dental cases. Sir James Craig pointed out that the exception in regard to "urgent" cases was impracticable, and that no case had been made for the prohibition of the practice of dentistry by medical practitioners. He was supported by Dr. O'Dowd and Mr. Hennessy and by several lay deputies. Mr. McGilligan, the Minister in charge of the Bill, said that he did not stand by the clause, and that he would leave the decision to the House. It could be discussed further in Committee.

It is unfortunate that a provision establishing a grave precedent in regard to the privileges of the medical profession should have been introduced into a Bill without previous consultation with representatives of the profession. The Bill was drafted in consultation with representatives of the dental profession, and, as far as is known, no independent medical opinion was sought.

Royal College of Physicians of Ireland.

At the annual business meeting of the Royal College of Physicians of Ireland, held on St. Luke's Day, Dr. William Arthur Winter was elected President. The following were elected Censors: Dr. B. Solomons, Dr. F. X. Callaghan, Dr. V. M. Synge, and Prof. J. W. Bigger. The President nominated Dr. Solomons as Vice-President. The several College officers and examiners were elected. In the evening the College dinner was held for the first time since 1921, about 100 Fellows and guests being present. Among the principal guests were the Chief Justice of the Irish Free State, the Provost of Trinity College, the President of the Royal College of Surgeons in Ireland, the President of the Royal Academy of Medicine in Ireland, the Dean of St. Patrick's, and the Archdeacon of Dublin. In the course of the evening a telegram of greeting was received from the Royal College of Physicians of London.

Dublin University Biological Association.

The opening meeting of the Dublin University Biological Association was held in Trinity College last Saturday evening, when the President-elect, Prof. J. W. Bigger, read a paper on the Expectation of Life and the Bacteriological Laboratory. He pointed out that the expectation of life might be increased by postponing the age of death or by preventing avoidable death. In the period 1920-22 the expectation of life was greater by 14 years than in the period 1871-80, and in the last half-century the death-rate had fallen by 21 per cent. He went on to show that the expectation of life had increased side by side with the increase of knowledge gained in the bacteriological laboratory. He showed in the case of several diseases how science had diminished the death-rate. He pleaded for a wider recognition of the value of preventive medicine, and for more adequate provision for research. The paper was discussed by Prof. F. E. Wynne (Sheffield), Prof. E. E. Glynn (Liverpool), Prof. W. St. C. Symmers (Belfast), and Dr. W. L. Treadway (U.S. Medical Service).

Workmen's Compensation.

The senior surgeon to the Meath Hospital, Mr. Lane Joynt, delivered an address to the students of the hospital at the opening of the session on Oct. 14th, on various aspects of the Workmen's Compensation Acts. Considering that the Act has been in force sufficiently long to estimate how it had worked, he found prejudice had been overcome and its benefits were more generally known, the medical profession not always showing to advantage in these cases, and not always aiding the courts as much as it might. Many doctors, he warned his hearers, thought they were hired as fighting men for the particular master who employed them, the attitude, proper in a lawyer, not being in keeping with the traditions of the medical profession. A medical man might be called to give evidence of fact firstly and secondly as to the probable effects of any injury on a man's future health. The latter was a matter of opinion, but should be given regardless of what is affected from a monetary point of view. The insurance companies relieved the employer of his liability under the Act and were bound to protect themselves, and in so doing employed the medical men best qualified not only to give them expert advice but who were accustomed to appearing in legal cases and were not upset by cross-examination. The workman, on the other hand, generally only had the advice and help of a house surgeon or of a practitioner unaccustomed to courts of law, who under cross-examination by skilled lawyers frequently failed to do justice to their patients or themselves. He concluded with reflections that ought to be widely recognised by the public as well as the medical profession. For he pointed out that hospitals reduced the sums insurance companies would otherwise have to pay, and yet the companies did not subscribe anything like an adequate amount. Without the hospital treatment most workmen's injuries would result in life pensions. Artisans and workmen were now in a better position than formerly. The change in the distribution of wealth had an adverse effect on hospital funds, and they were now forced to demand some payment from every patient.

BUCHAREST.

(FROM OUR OWN CORRESPONDENT.)

The Treatment of Epididymitis.

Prof. Bradiceanu recently outlined the method of treating gonococcal epididymitis employed at the Polyclinic in Bucharest. Upon the development of pain in the epididymis all urethral injections are stopped, and the patient is sent to bed and put upon a fluid diet. Free catharsis is ordered, together with mild urinary sedatives. Every second day some protein preparation is injected intramuscularly, and eventually also some gonococcus serum or vaccine is administered. Locally, in the last series of cases experimented upon, belladonna or ichthyol or iodine ointment, or an ester of salicylic acid has been used. The latter is a clear liquid, freely miscible with animal and vegetable oils. Medicinally, it is characterised by the fact that when painted on the unbroken skin it is absorbed and circulates in the blood as sodium salicylate. This drug, when applied to the scrotum once a day, produces a local feeling of warmth, no inflammation of any importance, but occasionally a fine desquamation. Within a period varying from 12 hours to 7 days, the pain is very

largely controlled. As soon as this has been accomlished, swelling of the organ is reduced by the pplication of mercurial ointment locally and iodide f potassium internally, and by careful strapping. n applying the straps, care should be taken at first o confine the testicle to the lower part of the scrotum y a band of adhesive plaster passed tightly around ie scrotum above it. The strips which cover the wer part of the scrotum should begin and end at is circular band as a fixed point, and should be awn tightly at intervals of a few days until the velling has disappeared.

Suicide by Carbolic Acid.

The use of carbolic acid is not a passing fad among nicides, at any rate in the Near East. It is an tablished custom, due primarily to the fact that the gitimate uses of the acid are so numerous that it is sy for almost any person to give a druggist a plausible ason for its purchase. Death by carbolic acid is eath by torture, but the would-be suicide who is in al earnest does not stop to bother himself about a w moments or a few hours of agony. The umanian Pharmaceutical Association favours the assing of a new law regulating the sale of this ison, and the council will do well, says the *Clujul edical*, to give the proposal careful consideration. is said that the placing of restrictions upon the e sale of concentrated solutions will do much od, with little inconvenience to the public, asmuch as the more dilute solutions are perfectly tisfactory for most legitimate uses. The conntrated solutions are fatal, but the weaker solutions e not very dangerous. There is reason to believe at a properly framed ordinance would reduce the mber of suicides.

Prohibition of Alcohol in Medicine.

An effort is to be made by the Bucharest Council Public Hygiene to direct legislation to prohibit e sale of such patent medicines as contain alcohol excess of the quantity sufficient or absolutely cessary to preserve them. At a recent meeting the Council the question was again discussed in its bearings and analyses were produced of several the well-known patent medicines, most of them foreign origin, which proved somewhat of an eyeener for some of those present. It was abundantly own that there was from 14 to 40 per cent. of alcohol many of these preparations, and that it was thing more than the brandy habit which caused many people to patronise these so-called cure-alls l vitalising liquors. For years the medical press s been calling attention to the fact that their rtues, if there were any, were merely due to the ohol they contained, and it is gratifying that sistent and consistent agitation has brought the porters of temperance into line, and that they uniting as a body in controlling the evil.

LEICESTER ROYAL INFIRMARY.—It has become essary to reconstruct the central ward, the last of the inal wards of 1861. Of the 80 patients displaced during rebuilding, 30 will be provided for in a temporary ward ch is already under construction, and it is hoped to mmodate the remainder in the Hospital Saturday ety's convalescent homes.

NEWCASTLE INFIRMARY ENLARGEMENT. — The ernors of the Royal Victoria Infirmary, Newcastle-upon-e, find themselves compelled to face an expenditure £150,000 for its extension. Since the building was ed in 1906 the number of in-patients has nearly trebled, patients have increased sevenfold, and now average a day; and where, 21 years ago, there were 4000 operas there are now nearly 14,500. The hospital is badly crowded, yet the waiting list numbers more than 2000. large expenditure contemplated is made immediately ssary by the expiration at the end of March next of lease of the adjoining buildings of the Ministry of sions Hospital when they revert to the infirmary. They t then be so adapted as to provide a large number of , extend the out-patient department, and afford insed accommodation for nurses and domestic staff. The mary, which serves the counties of Northumberland and ham, with a population of two millions and a quarter, is only teaching hospital between Leeds and Edinburgh.

Public Health Services.

LIVERPOOL PORT SANITARY AUTHORITY: ANNUAL REPORT.

IN his interesting report for 1926 Dr. A. A. Mussen mentions 5613 visits of inspection that were paid to ships, of which 930 had nuisances on board on one or more of their visits; there were 3099 dirty forecastles, but only 251 foul water-closets (last year he reported 681). He devotes a chapter to the hygiene of crew spaces, in which he remarks that accommodation for crews is improving and is now often at the after end of ships, where men get more room, better ventilation and lighting, and less weather stress. He has accumulated evidence about conditions in the larger cargo ships with white crews that use the port of Liverpool, and found that of the 187 ships built before 1916 only 20 per cent. had their crew accommodation aft, while of the 211 built since 1916 70 per cent. were thus constructed, the seaman in most of the modern ships no longer living in the forecastle. Other improvements to be noted were cubicles fitted in 28 per cent. of the 211 newer ships, the former proportion being 1·8 per cent.; mess rooms in 63 per cent. against 12; washhouses (or wash places) in 92 against 66; baths in 7·5 against 0·5; and hospitals in 50 per cent. against 24. Similar improvements were made in ships for lascar and mixed crews, and in the smaller cargo steamers as well. We still know too little of the diseases from which seamen suffer, beyond what can be learned from the Board of Trade's annual return of their deaths, but in this report we are told what infectious diseases occurred among the large number of crews and passengers during the many voyages of the ships that reached Liverpool during the year. Of the 237 malaria patients, 202 were seamen; of 91 with pulmonary tuberculosis, 41; of 23 "other tuberculosis," 12; of 65 with chicken-pox, 28 were passengers, the ship's doctor and 36 natives supplying the balance; of 59 with measles, 7 were seamen; of 58 with pneumonia, 36; of 41 with enteric, 30; of 5 with smallpox, 3; of 4 with plague, all were seamen, but no plague case was landed at Liverpool. From this we may gather that the infectious diseases that most affected seamen were malaria, tuberculosis, pneumonia, and enteric fever—plague has always been recognised to be a special risk of seamen.

The fear of plague arose in Liverpool during the year on two separate occasions. A boy was, on August 28th, admitted to the Northern Hospital, Liverpool, where he died in two days of the disease, no case having occurred in the city for several years. His father visited the hospital, was examined and found to be suffering from plague, with a small inguinal bubo. He recovered in three weeks. This father was a watchman in the South Dockyard. The most exhaustive and careful search for plague rats was at once undertaken, both in port and city; none was discovered. While attention at the docks was thus focused upon plague, the ss. *Zaria*, on her way to the port from Lagos, West Africa, reported, on Sept. 10th, that two native firemen had died on board from plague, each with a bubo and high fever. The *Zaria* arrived at the port on Sept. 12th, and was met and inspected by the assistant port medical officer, three sanitary inspectors, two rat catchers, and two rat searchers. Naturally every person on board was carefully examined, but no case of plague was found, nor did any develop later. The ship and her cargo were dealt with thoroughly, and she was fumigated. One hundred rats were found on board her, 42 of them were dead, 38 were trapped, and 20 killed by hydrocyanic acid fumigations; 31 per cent. were plague-infected. Thorough precautions were taken to prevent infection of the rats ashore, and apparently with success, for no plague rat was found among the 6805 from the city and port examined during the year. Captains of ships now report by wireless if they have any infectious or suspicious case on board

or have been within two months in a suspected harbour; thus much time is saved to them, medical inspection being carried out immediately on arrival. The rats captured and destroyed were, on ships 36,265, on the quays 2562, and in the city 16,185, in all 55,012, a number 6000 less than in 1925, so perhaps the active and persistent campaign in Liverpool is at last reducing the rat population. As usual there were few black rats ashore, few brown rats afloat. No mention is made this year of the new rat-guard for hawsers recommended in the last report, but valuable original observations by two rat-catchers on the evidences of rat infestation on ships are given. Thus they report that one rat in 24 hours ate out the soft portions of 425 grains of maize. Now that is a quarter of a pound, and maize costs 35*s*. a quarter (480 lb.), so the 18,747 rats killed in Liverpool in city and port in the year, if they had lived there only three months, had already eaten, measured in maize, £1550, and the 36,265 in ships, £3000. Besides there is the damage they cause. So the campaign for their reduction has financial value, as well as sanitary reason.

The venereal clinics have this year been attended by larger numbers; 1360 new cases were seen in the seamen's dispensary; we gather that not all were seamen. Some 15 per cent. attend but once, and another 15 per cent. discontinue treatment before they are non-infectious. Of every 10 cases 3 were syphilis, 6 gonorrhœa, and 1 soft chancre. Lectures are given on the dangers of venereal disease in the first-aid and hygiene courses for mercantile marine cadets, and also to boys elsewhere in the city. The 17,781 aliens examined were almost all from North America and were clean; only ten certificates of rejection were issued. The medical inspection room wanted last year has been obtained. Half the emigrants and other passengers leaving Liverpool went to Canada. Verminous transmigrants are dealt with at the city hospitals. Emigrants, second or third class, for the United States are inspected by officers of the U.S. Public Health Service. All emigrants are inspected by the medical officers of the Board of Trade (23 were rejected for infectious disease), also the crews of all vessels bound for America.

The new Public Health (Imported Food) Regulations, 1925, have greatly simplified the work of meat inspection; 340 tons of meat were condemned for faulty preservation, 88 tons of canned goods, 2000 tons of fruit, 2000 tons of cereals. Anyone can see that much illness of many sorts has been spared the public by the admirable work of this port sanitary authority.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 15TH, 1927.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 124 (last week 149); scarlet fever, 2463; diphtheria, 1271; enteric fever, 81; pneumonia, 849; puerperal fever, 37; puerperal pyrexia, 114; cerebro-spinal fever, 4; acute poliomyelitis, 23; acute polio-encephalitis, 4; encephalitis lethargica, 19; dysentery, 5; ophthalmia neonatorum, 104. No case of cholera, plague, or typhus fever was notified during the week.

Of the cases of acute poliomyelitis and acute polio-encephalitis taken together, 5 were notified from the East Riding of Yorkshire (2 only of these from Kingston-upon-Hull), the remainder distributed widely over the country.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 14 (0) from measles, 5 (1) from scarlet fever, 6 (3) from whooping-cough, 32 (5) from diphtheria, 72 (12) from diarrhœa and enteritis under 2 years, and 51 (7) from influenza. The figures in parentheses are those for London itself. The number of stillbirths registered during the week was 231 in the great towns, including 34 in London.

Correspondence.

"Audi alteram partem."

PLACE-IN-FAMILY AND DISEASE.

To the Editor of THE LANCET.

SIR,—I have read Dr. Still's lectures with muc interest. It appears to me futile to attempt a investigation of this most interesting problem unle full account is taken of the healthy-remaining membe of a given community. Dr. Still clearly sees th difficulty, as stated on page 796, but I think he brush it aside too lightly. Let me illustrate my objectio

TABLE I.

No. of families.	Children in each.	Total children.	Place-in-family.				
			1st.	2nd.	3rd.	4th.	5th
400	1	400	400	—	—	—	—
300	2	600	300	300	—	—	—
200	3	600	200	200	200	—	—
100	aver. 5	500	100	100	100	100	10
1000	—	2100	1000	600	300	100	10

All the figures are, of course, merely assumption nevertheless, they will illumine the point. Leavi out of account the childless families, neglecting al here for simplicity's sake miscarriages and st birth, the number of families with one child is evident

TABLE II.—*Incidence of Disease.*

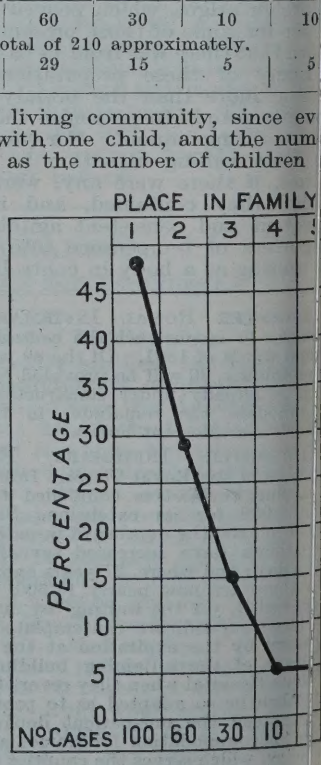
Place-in-family—	1st.	2nd.	3rd.	4th.	5th
	40	—	—	—	—
	30	30	—	—	—
	20	20	20	—	—
	10	10	10	10	10
Total (= 210).	100	60	30	10	10
Per cent. of total of 210 approximately.					
	48	29	15	5	5

the largest in every living community, since ev family has to begin with one child, and the num of families decreases, as the number of children family increases.

Let us assume a community of a thousand families, of whom 400 have one child, 300 have two children each, 200 have three children each, and 100 have more than three children, say average 5. We then get the results shown in Table I.

Now let us assume that there is an incidence of disease *unaffected* by place-in-family, or age, and that this amounts to 10 per cent. of the children. We then get results as shown in Table II.

Entering these into Dr. Still's schema we get a curve, which I show here, very similar to Dr. Sti



he exact shape of which will, of course, depend ntirely upon the ratios of the families with ifferent number of children one to another.

I contend that unless the exact number, and ence the proportion of the unaffected children, is scertained, no reliable results can be calculated.

I am, Sir, yours faithfully,

A. WOHLGEMUTH, D.Sc. Lond.

Shortlands, Kent, Oct. 22nd, 1927.

To the Editor of THE LANCET.

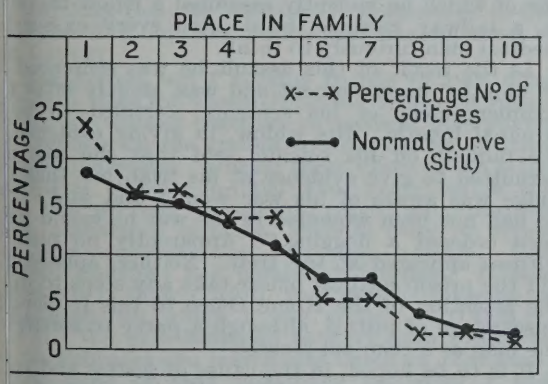
SIR,—In an investigation last year into some of ıe circumstances associated with the development goitre in children, included in the annual report the school medical officer for Lancashire, I noted ıe position in the family occupied by the goitrous ıild. The mothers were closely questioned as to ıeir children and all pregnancies were included so r as their memories went. As the interrogation ok up considerable time only 90 families, containing 5 goitrous children, were investigated (360 cases goitre were noted among 2600 children examined) that the material needs expansion. It is interesting compare the figures (shown in the table) obtained r these goitrous children with the standard dis- ibution suggested by Dr. Still in his Ingleby Lectures.

able showing percentage of all Goitrous Children Occupying Position in Family Stated.

(A) = Standard (Still). (B) Goitre (Cronk).

	Position in family.									
	1	2	3	4	5	6	7	8	9	10
() ..	18·5	16·1	15·4	13·4	10·8	7·5	7·6	3·9	2·1	1·7
() ..	23·4	16·6	16·6	14·0	14·0	5·2	5·2	2·6	1·7	0·9

In the graph which I have drawn from this table i will be seen that children from the first to the fifth i: lusive appear more liable to acquire goitre than



o ers. This suggests that the environment, particu- l y food, has a good deal to do with goitre, since the f ily circumstances immediately become straitened w h the arrival of children and improve again as s n as a child attains the age of 14 years and starts e ning, as they all do in this district.

I am, Sir, yours faithfully,

shton-on-Mersey, Oct. 19th, 1927. H. L. CRONK.

To the Editor of THE LANCET.

SIR,—In relation to Dr. Still's articles on Place-in- F nily as a Factor in Disease, there is an interesting p nt in pre-Napoleonic French law. Under this c e the *second* of twins was considered to be the h r. This was founded upon a theory of conception, b ; the underlying fact may have been that the second t be born proved to be the healthier. This I have n means of verifying.

I am, Sir, yours faithfully,

indon, Oct. 24th, 1927. A. R. MCCLURE, M.B.

ADRIAN STOKES MEMORIAL FUND.

To the Editor of THE LANCET.

SIR,—At a meeting held in Trinity College, Dublin, on Oct. 17th, with the Provost in the chair, it was decided to inaugurate a memorial to the late Prof. Adrian Stokes, who died of yellow fever, contracted during research work on that disease in Lagos.

It was the opinion of the meeting that Stokes's connexion with Dublin and with Trinity College—as student, as assistant to the professor of pathology, and as professor of bacteriology—could best be commemorated by the foundation of a scholarship, prize or medal, in connexion with the study of pathology and bacteriology in Dublin University. An executive committee was appointed and was empowered to collect funds and to consider a suitable form of memorial, the exact form of which will depend on the amount collected.

Those who would like to take part in the establishment of such a memorial to one of Trinity's ablest and most loved sons are invited to send their subscriptions to the hon. treasurers of the fund: Mr. Robert Russell, S.F.T.C.D., and Prof. A. F. Dixon, Sc.D.—We are, Sir, yours faithfully,

SETON PRINGLE, F.R.C.S.I.,
JOSEPH W. BIGGER, M.D.,
Hon. Secs.

School of Pathology, Trinity College, Dublin, Oct. 19th, 1927.

BILATERAL ARTIFICIAL PNEUMOTHORAX.

To the Editor of THE LANCET.

SIR,—The very interesting account by Dr. McLaughlin in your issue of Oct. 1st of a case of bilateral pulmonary tuberculosis treated by bilateral artificial pneumothorax credits me with having been the first to publish the method. I always thought this was so until recently, when it was brought to my notice that Prof. Ascoli,[1] of the University of Catania, Sicily, proposed it at the International Tuberculosis Congress held in Rome in 1912, the year in which I treated my first case. The reasons he gave for the treatment, with an account of cases treated, were reviewed by his pupil, Fagiuoli,[2] in 1914. Ascoli argued that since a pneumothorax was pathological, in a case of tuberculosis treated by pneumothorax, two pathological conditions were present; that complete collapse might, therefore, make the conditions worse than those it was intended to relieve, and that better results would likely be obtained by bilateral "low pressure pneumothorax." On the other hand, I maintained that in consequence of the pressure in the pneumothorax being the same throughout the cavity, a differential effect which has been termed "selective pneumothorax"[3] or "pneumothorax electif"[4] is produced, and that this results in the lung expanding according to its elasticity. The healthy parts, therefore, expand freely, bulging into the cavity and displacing the gas which finds lodgment over the diseased parts. These having lost their expansile properties remain quiet instead of being pulled against the expanding chest wall. If these points of view are considered, I think it will be generally conceded that that of Prof. Ascoli is largely empirical, while mine has a definite physical basis, which brings the method of treatment into line with the rest treatment of other forms of tuberculosis. However, to Prof. Ascoli must be given the credit of having first published the method.

I am, Sir, yours faithfully,

WM. PARRY MORGAN.

THE BIRTH CONTROL INVESTIGATION COMMITTEE.

To the Editor of THE LANCET.

SIR,—There is no reasonable doubt that birth control is practised by a large number of married people of all classes. It is to be supposed that the usage may have important effects on the physical, psychological, and ethical well-being, not only of the individuals who employ it, but also indirectly on the well-being of the children of those persons, and therefore of the whole community. It is also probable that if birth control is desirable, some methods are to be preferred to others, yet up to the present little scientific study has been made, either of the comparative advantages of different methods, or of the possible far-reaching effects of the practice as a whole.

The subject of birth control has, hitherto, not formed part of medical education, and, generally speaking, any professional knowledge that medical practitioners may have of this question has been acquired in response to a demand from their individual private patients. In hospitals and medical schools, general instruction in this subject is not as a rule given to the students, nor information to patients. Yet it is well known that in certain cases of ill-health further pregnancies are clearly contra-indicated on medical grounds alone.

A committee composed of scientific workers and members of the medical profession, assisted by lay workers and others interested in the problem, has been formed to promote the scientific investigation of birth control. The members of the committee differ widely in their opinions as to the desirability of birth control, but are united in the realisation that the practice is widespread, and that the scientific problems which it raises can no longer be ignored. It is realised that the results of the investigation may show that no entirely satisfactory method has at present been discovered, and work is being done to find new methods. It is hoped also that relations may be established with clinics and other organisations connected with birth control abroad, so that their experience and knowledge may be used.

The committee serves no propagandist function, but desires only to establish facts and to publish these facts as a basis on which a sound public and scientific opinion can be built. The present division of medical opinion and the lack of any orthodox medical teaching on the subject are largely explained by the absence of available data, on which a sound opinion can be formed. The committee will be grateful if any of your readers who may be interested in the subject, or who possess data that would yield information, would communicate with the honorary secretary of the committee, the Hon. Mrs. Marjorie Farrer, 41B, Clanricarde-gardens, London, W. 2.

A questionaire has been prepared by the committee which, if filled in in sufficient numbers and in a sufficient variety of cases, will provide that quantity of accurate statistical information which is now lacking. As many of these questionaires as may be required will be sent to any private doctor, hospital, welfare centre, or infirmary, on application to the honorary secretary of the committee.

I am, Sir, yours faithfully,

HUMPHRY ROLLESTON,
Chairman.

Oct. 25th, 1927.

PAYMENT TO HOSPITALS FOR MOTOR ACCIDENTS.

To the Editor of THE LANCET.

SIR,—At a meeting of the Norfolk and Norwich Hospital authorities reported in THE LANCET on p. 892 last week, "it was pointed out that a private practitioner to whose surgery a motoring victim was taken could send his bill to the insurance company, and that the hospital could put itself in the same position as a private practitioner by sending all its motor cases to the new paying ward."

It would be of great interest to hear whether this statement is based on legal opinion, and if so, to read the question submitted together with the ans given. Up to now it has always been taken that contract, if any, is between the private practiti and the victim, and that the same situation ap in the case of the voluntary hospital, whether victim goes to the general or private wards. Bu the majority of cases the victim is not in a condi to enter into any contract before treatment therefore a legal contract cannot be brought existence. How will putting the victim in a pri bed get over the difficulty?

I am, Sir, yours faithfully,

Hove, Oct. 25th, 1927. E. ROWLAND FOTHERGIL

"HIVES."

To the Editor of THE LANCET.

SIR,—In THE LANCET of Sept. 24th, p. 664, notice of Dr. W. W. Duke's book on "Allergy Anaphylaxis," your reviewer asks for a definitio the uncommon expression "hives." This is but of the many words, now considered American, w were once common in this country, and are still t heard as local idiom. "Hives" is the current t in Ulster and probably elsewhere for the urtic eruption produced by the harvest bug (*Le autumnalis*). It thus comes to mean any vesicular eruption produced in protein-sens testing. I am, Sir, yours faithfully,

J. JOHNSTON ABRAHA

Harley-street, W., Oct. 25th, 1927.

THE CASE OF GEORGE JORDAN.

To the Editor of THE LANCET.

SIR,—This case of an ex-Service man who rece a shrapnel wound of the head during the wa fragment remaining in the brain which could no removed by operation) which produced occasi attacks of Jacksonian epilepsy and mania, du one of which he violently assaulted a fellow trav in a railway carriage, must give every ex-Ser medical man furiously to think.

As the result of this assault he was sentence 18 months' imprisonment and was, shortly after commencement of his sentence, certified to criminal lunatic. His widow, in giving evidenc the inquest on his suicide, said that she was permitted to give evidence at his trial, but that judge was aware of his war wound and said: he had not been wounded in the war he would been ordered a flogging." Apparently no me witness appeared at the trial. Neither, appare did the prison medical officer take any steps to the attention of the Home Office to this intole miscarriage of justice, although a party to certif the man as a criminal lunatic.

It is to be hoped, in the cause of justice and petency, that this case will be fully investigated, both judge and police and prison medical off be given an opportunity of explaining their appar inexplicable conduct.

I am, Sir, yours faithfully,

H. WANSEY BAYL

Harley-street, W., Oct. 21st, 1927.

*** We comment on this case elsewhere.—ED L

THE REPORT ON SCARLET FEVER.

To the Editor of THE LANCET.

SIR,—I have to thank Dr. J. A. Milne for dra attention to an error on page 9 of the recently iss report of the Ministry of Health on scarlet fe Carbolic lotion 10 per cent. is there referred instead of carbolic oil, as it should have been wri and is written on other pages which described technique of the Milne treatment as introduced his father, the late Dr. Robert Milne.

I am, Sir, yours faithfully,

Oct. 24th, 1927. ALLAN C. PARSON

MISLEADING QUALIFICATIONS.

To the Editor of THE LANCET.

SIR,—All Fellowships in medicine and surgery rank higher qualifications, and the vast majority of llows of the Irish and Edinburgh Royal Colleges Surgeons take pride in their particular Fellowship using the correct letters F.R.C.S.I. and F.R.C.S.Ed. the surgical world the English Fellowship is ognised to be the highest surgical distinction; it a compulsory passport to admission to honorary gical appointments in all teaching English hospitals, d many Edinburgh and Irish Fellows endeavour obtain it after acquiring their own. It is doubtful the Edinburgh Fellowship can be regarded as a rely surgical distinction; it is open to practiners practising dentistry, midwifery, gynæcology, d other kindred subjects on examination in their n specialty plus an examination in general surgery, d there is no primary examination in anatomy and ysiology, nor a compulsory examination in operans on the dead body.

In regard to designations, F.R.C.S. states that a ctorate of Medicine is on a parallel with a Fellowp. A doctorate once conferred cannot be taken ay; a Fellow can be deprived of his Fellowship infringement of the particular regulations perning to his own College. A truer comparison in ms used is that between Fellowships of other Royal leges or Societies. In regard to science distinctions, Fellowships of the Royal Society of Edinburgh and of the Royal Society, London, are high distinctions, but the latter, of course, by far the more exclusive; F.R.S.E. is rigidly used in designating the former; to omit the E is to presume a much higher distinction.

Similarly in England anyone who is not an English Fellow, but who designates himself only as F.R.C.S. in hospital and other publications, renders himself subject to the suggestion that he wishes the public to think, as in point of fact they do, that he is in possession of the higher qualification. This is misleading; is it not unethical?

As this subject involves all the Fellowships, it is one which could be settled by the councils of the Royal Colleges concerned by a mutual agreement on the designations which they expect the various Fellows to adopt.—I am, Sir, yours faithfully,

Oct. 17th, 1927. ETHICS.

To the Editor of THE LANCET.

SIR,—I read with interest the remarks of F.R.C.S. in your issue of Oct. 15th. There is still an idea prevalent in London that the Edinburgh F.R.C.S. is a walk-over. If anyone goes up with that idea he will get a rude shock and a polite request to come again. As far as I am able to judge there is no material difference between the standard of the Edinburgh F.R.C.S. and the final of the F.R.C.S. Eng.; indeed the requirements in pathology are often considered to be higher in the Edinburgh examination.

I am, Sir, yours faithfully,

Oct. 19th, 1927. NOT YET F.R.C.S.

Obituary.

E LATE MAJ.-GEN. SIR WILLIAM MACPHERSON.

ir Patrick Hehir writes: "I esteem it a great our to be allowed to add a few remarks regarding late Maj.-Gen. Sir William G. Macpherson to the prehensive obituary notice that has appeared in E LANCET.

Macpherson and I became friends in 1906 after return from the Russo-Japanese War, and subsentlv we worked together on medical manœuvres exercises on the ground without troops on large medium scales. During these exercises he acted Medical Director-in-Chief and, years before the at War we were already (on paper) using hospital ns, ambulance columns, hospital ships on rivers other appurtenances of modern warfare. One hese exercises has particular interest. It was ied out in March, 1913, and was the invasion of hanistan, on which I was acting as D.D.M.S., f C. We were supposed to start from Peshawar y in February and march into Cabul on June 26th. the close of that imaginary campaign I had ral ambulance columns, two ambulance trains, two hospital ships on the Cabul River. By an aordinary coincidence I was P.M.O. of the 1919 hanistan campaign, and although we did not ance beyond Dacca, the war, from the medical t of view, was conducted on much the same lines n the exercise referred to, the only notable differ: being that the river was not used as it is navigable in the early months of the year; 1919 campaign began in May and ended in ust.

During the Great War we were brought into nate relations. I was attached to Lieut.-General Arthur Sloggett, Director of Medical Services of Armies in France, for instructional purposes. w what was being done with the 21 hospital ns, the 15 ambulance columns, the clearing itals, and field ambulances of the British Armies he beginning of the second Somme enterprise. way these were being concentrated behind the t lines at the exact spots necessary, as if by magic, medical efficiency in the field developed to the highest pitch of perfection. In his war work Macpherson was a constant source of inspiration to others."

Westward Ho, Devon, Oct. 23rd, 1927.

JOHN RUDD LEESON, M.D. EDIN., J.P.

Dr. J. R. Leeson's death on Oct. 23rd removes a medical man with a high record of public service. His early years as a student are described in a book published last spring at the time of the Lister centenary. Born in 1854 he entered St. Thomas's Hospital about the time when the new buildings by Westminster Bridge came into use, and he could testify from personal experience to the ravages of septic diseases even in institutions whose arrangements were as perfect as they could be made before the recognition of Lister's discoveries. In those days the medical curriculum occupied only two and a half years, the first of which was spent in dissection and attending lectures. Towards the end of this training Leeson asked a member of the staff, the great Charles Murchison, how best he should spend the remainder and Murchison unexpectedly advised him to go to Edinburgh and study the new methods of Prof. Lister. He took this advice and in 1873 became one of Lister's dressers, soon falling under his influence and becoming an earnest disciple. After qualification in 1875 and study at Vienna and Berlin, he returned to London to join the resident staff of St. Thomas's Hospital, where he became demonstrator in anatomy in 1878. He served for a time as ship's surgeon, graduated as M.D. Edin. with commendation in 1882, and settled in practice at Twickenham, where he spent the rest of his life, being associated especially with the St. John's Hospital and the Metropolitan and City Police Orphanage. Always a keen observer, Dr. Leeson wrote freely not only on medical subjects, but on geology and natural history. He was a Fellow of the Royal Astronomical, Royal Microscopical, Geological, and Linnean societies, and was also interested in many aspects of social work. At the time of his death, in his seventy-fourth year, he was Mayor of Twickenham, a magistrate for Middlesex, and a member of the Court of the Salters' Company.

Dr. Leeson was twice married. His son, Mr. Spencer Leeson, is headmaster of Merchant Taylors' School.

Medical News.

UNIVERSITY OF DUBLIN: SCHOOL OF PHYSIC, TRINITY COLLEGE.—At recent examinations the following candidates were successful :—

FINAL MEDICAL EXAMINATION.

Part I. Materia Medica, Medical Jurisprudence, Pathology, &c.—M. H. Fridjhon, R. St. J. Lyburn, H. T. Fleming, W. R. Johnston, J. N. U. Russell, J. E. C. Cherry, A. J. Garde, R. M. Wilson, C. R. Harris, R. I. Reid, C. King, J. F. K. MacCarthy-Morrogh, A. H. O'Malley, Anna M. J. M'Cabe, and F. S. Mackenna.

DIPLOMA IN PUBLIC HEALTH.

Part II.—Kathleen M. Kennedy, Meave Halligan, Sarah M. Coghlan, and Brenda M. Young.

UNIVERSITY OF EDINBURGH.—At a graduation ceremonial held on Oct. 22nd the following diplomas were conferred :—

D.P.H.—Walter T. de Silva, Eric F. Dott, Ronald A. Macdonald, Donald P. MacIver, John Macleod, and Elizabeth P. M'Whirter.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At recent examinations the following candidates were approved :—

FINAL EXAMINATION.

M. M. Wright, F. A. Buttner, Theophilus Lotter, M. A. H. Gohar, K. R. Mali, G. D. Roche, M. M. Farghaly, K. R. Trembath, P. McK. Logan, Samuel Jurawan, T. B. Dobson. Supiramamain Kulanthaivalu, Ponniah, Ram Chandra Adhikari, John S. T. Isbister, George M. Johnson, Clarence D. C. Golding, Albert A. Huse, Sandaman Sivalingam, Ramanather Kandish, Suppiah Kanagalingam, Israel, Gurland, Edmund A. Bulankulane, Arnold W. Green, Bola Dayanand Rao, Walter Campbell, Alexander C. Lovett-Campbell, William Jackson, Joseph W. A. McGuinness, Adam S. Gordon, Thomas A. W. Wilson, William T. A. Pearce, Tan Chang Yan, Geoffrey W. Milledge, William Ainlsie, and Alfred Bitini Xuma.

Medicine.—Ellaman Siva Rama Menon, Mohamed Ralman Ramjohn, Arthur B. Anderson, Herbert F. W. Slane, Ramchandra Ganesh Paranyape, Bertram J. Ess, Simathamby Chelliah, Veerasekeram Sinnetamby, and John E. Felix.

Surgery.—David A. Herd, Frederick H. Emery, James Masilamani, Maurice Klar, and William Wallace.

Midwifery.—David A. Herd, Cyril A. Munro, Agnes Donaldson, Ellaman Siva Rama Menon, Sundar Singh Nagi, Arthur B. Anderson, Herbert F. W. Slane, Sinnethamby Chelliah, Joseph M. Chittambatam, Hubert Lelizab Clement de Silva, and George R. Gardner.

Medical Jurisprudence and Public Health.—George Henderson, Norman J. W. Smith, Matthew I. Mullen, Ewen L. Fraser, Andreas Johannes de Villiers, Ramchandra Ganesh Paranyape, Wilfred Kelly, Gavin W. Campbell, and Mark Lessnoff.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on Oct. 19th Mr. Alexander Miles was elected President for the ensuing year, Dr. A. Logan Turner Vice-President, and Mr. John William Struthers Secretary and Treasurer.—The following 25 successful candidates, out of 93 entered, who passed the requisite examinations on July 28th, were admitted Fellows :—

John M. Bassett, William A. Blomfield, William M. Brown, John H. Couch, Albert F. W. da Costa, Hari Dass, George F. Duggan, Caroline A. Elliott, Gilbert M. Irvine, William H. G. M. Ling, Henry C. Lowry, Robert R. Macintosh, Ian Macpherson, Richard B. Martin, Robert S. Melville, Angus J. Murray, John S. Ramage, Bunganath Krishna Rau, Eugene J. Ryan, Richard Vyayaratram Nevins Selvadurai, Matthew A. Swan, Thomas E. Stoker, Beriah M. G. Thomas, James Troup, and James N. Young.

At recent examinations the following candidates were successful :—

FINAL EXAMINATION FOR L.D.S.

Athelston E. Thornhill, Robert C. B. Heele, Norman A. W. Ramage, Gladys E. Munro, Alastair D. Walker, Annie M. Kean, Charles J. Hodge, Alexander H. Brown, and Thomas S. Macfarlane.

Pathology.—Mary M. Hunter, Francis P. MacGillivray, Ronald McA. Blair, William G. Hetherington, Joseph G. Medcalf, Jean F. Miller, and Roger H. White.

Medicine.—Mary M. Hunter, William G. Hetherington, and Robert M. Cameron.

Surgery.—Mary M. Hunter, William G. Hetherington, and Robert M. Cameron.

Dental Subjects.—Ronald D. Allison and Thomas W. Gregory.

BRISTOL GENERAL HOSPITAL NURSES' HOME.—Sir George Wills has presented a home for the nursing staff in memory of his wife. The building, which will be known as the "Susan Brittan Wills Home," and has just been opened, will accommodate 31 nurses.

SOCIETY OF APOTHECARIES OF LONDON.—At recen examinations the following candidates passed in the unde mentioned subjects :—

Surgery.—R. P. Charles, King's College and Charing Cro Hosps.; H. J. Harcourt, St. Thomas's Hosp.; B. D. Jai Charing Cross Hosp.; D. I. Jones, University College ar St. George's Hosps.; T. M. Joseph, London Hosp.; ar L. M. Saunders, Manchester.

Medicine.—J. D. Evans, St. Mary's Hosp.; G. Furnis Manchester; S. Goldman, London Hosp.; F. G. Hardake St. Mary's Hosp.; A. W. Lassowsky, Middlesex Hosp J. D. Ritchie, St. George's Hosp.; G. C. Rhys-Jone Charing Cross Hosp.; and S. Slotar, Guy's Hosp.

Forensic Medicine.—H. B. Blaker, St. Mary's Hosp.; J. Evans, St. Mary's Hosp.; T. M. Joseph, London Hosp J. D. Ritchie, St. George's Hosp.; B. Rosenzvit, Middles Hosp.; A. E. Vawser, London Hosp.; and L. Was Manchester.

Midwifery.—G. E. Bent, Manchester; H. B. Blaker, St. Mary Hosp.; H. M. Feldman, Leeds; D. I. Jones, Universi College and St. George's Hosps.; A. A. Leibovitch, Khark and London Hosp.; H. T. Rylance, Middlesex Hosp.; a V. R. Smith, Manchester.

The Diploma of the Society was granted to the followi candidates, entitling them to practise medicine, surgery, a midwifery: R. P. Charles, J. D. Evans, S. Goldman, F. Hardaker, B. D. Jain, G. C. Rhys-Jones, J. D. Ritchie, Rosenzvit, S. Slotar, and V. R. Smith.

WEST LONDON HOSPITAL POST-GRADUATE COLLEG The lecture-demonstrations given twice a week at t College are open to practitioners who are not taking t regular post-graduate courses. Particulars may be fou in our Medical Diary week by week.

HUNTERIAN SOCIETY.—On Monday, Nov. 7th, 9 P.M., at the Cutlers' Hall, there will be a discussion on t Legal Perils of the Doctor. The speakers will inclu Earl Russell, Dr. James Neal, Mr. Rayner Goddard, a Sir Herbert Waterhouse.

ROYAL SANITARY INSTITUTE.—A sessional meeti will be held at 90, Buckingham Palace-road, London, S.W on Tuesday, Nov. 8th, at 5.30 P.M., when Major H. Bar will give an address entitled the Royal Commissions Health and Housing: A Retrospect and a Forecast.

ROYAL SOCIETY OF ARTS.—On Wednesda Nov. 16th, at 8 P.M., Dr. Leonard Hill, F.R.S., will give address on Overcrowding in Public Conveyances. T meeting will be held at the Society's House in John-stre Adelphi, London, and Lord Dawson will take the chair.

NATIONAL ASSOCIATION FOR THE PREVENTION INFANT MORTALITY.—A course of lectures, for marr people only, on the Hygiene of Married Life and Pare hood will be given at Carnegie House, 117, Piccadi London, W., on Wednesdays from Nov. 2nd to Dec. 7 from 8.30 to 9.30 P.M. The lecturers will be Prof. Winif Cullis (Nov. 2nd), Lady Barrett (Nov. 9th), Dr. J. S. F bairn (Nov. 16th), Dr. Eric Pritchard (Nov. 23rd), Dr. C. Kimmins (Nov. 30th), and Prof. Louise McIlroy (Dec. 7t

FELLOWSHIP OF MEDICINE AND POST-GRADUA MEDICAL ASSOCIATION.—On Monday, Oct. 31st, at 5 P. at 11, Chandos-street, Cavendish-square, London, Lawrence Abel will deliver a lecture entitled, Points in Diagnosis and Treatment of Pyuria. On the same Dr. Donald Paterson will give a medical demonstrat at the Hospital for Sick Children, Great Ormond-str at 2.30 P.M., and Mr. Bright Banister a surgical dem stration at the Chelsea Hospital for Women at 2 P.M. lecture and demonstrations are open to members of medical profession without fee. Two courses begin Oct. 31st—viz., a four weeks' course at the London L Hospital, and a fortnight's course at the Hampstead Gen Hospital for general practitioners. From Nov. 7th to 1 the Hospital for Diseases of the Chest, Brompton, provide a comprehensive course. From Nov. 14th to 2 there will be a clinical course at St. Peter's Hospital, toget with a series of formal lectures on diseases of the urin tract. From Nov. 14th to Dec. 3rd a course in medic surgery, and gynæcology will be held at the Royal Wate Hospital, occupying the mornings and some afterno For those having only a short time at their disposal following two courses have been arranged: from Nov. 2 to Dec. 17th, at 5 P.M. daily, a series of clinical demons tions upon selected cases will be given in the out-pati department (in Welbeck-street) of the West End Hosp for Nervous Diseases, and from Nov. 21st, daily from to 6 P.M., for two weeks, there will be a course at the Lon Temperance Hospital for practitioners. A course will given at St. Mark's Hospital from Nov. 28th to Dec. Copies of syllabuses are obtainable from the Secretary the Fellowship at 1, Wimpole-street, London, W. 1, will be sent regularly to those who wish to receive the

IT is stated that the Mutual Property Insurance ompany's film, "The Risk of Diphtheria Banished," has ow been shown to more than 119,000 people.

THE cost of rebuilding the west wing of Middlesex ospital will be £241,511, and it is expected that the work ill occupy two years.

NATIONAL MEMORIAL TO QUEEN ALEXANDRA.—early £8000 has been produced by the opening of gardens England and Wales for the benefit of this memorial.

HELLINGLEY MENTAL HOSPITAL.—The Bishop of ewes has unveiled in the Chapel of St. Luke at Hellingley ental Hospital a stained-glass window provided by subriptions from the patients and staff and sundry friends. he designer was Mr. Percy C. Bacon.

DONATIONS AND BEQUESTS.—Mrs. Florence Baines, del, Leeds, left £1000 to Leeds General Infirmary and £500 the Leeds United Institute for the Blind, Deaf and umb, and £100 each to the Meanwood Convalescent Home r Children, and the Leeds District Nurses' Association.

ORDER OF ST. JOHN.—As a result of the new arter which the King granted last year a new system of nking was introduced, and some 120 honorary associates ve been transferred to the grade of officers, taking rank mediately after commander. The names of these ladies d gentlemen appeared in the *London Gazette* of Oct. 21st.

UNIVERSITY OF CAMBRIDGE.—Mr. Ernest Clarke, V.O., F.R.C.S., consulting surgeon to the Central London phthalmic Hospital, and President of the Section of phthalmology of the Royal Society of Medicine, has been ected an honorary Fellow of Downing College.

UNIVERSITY OF BIRMINGHAM.—A series of four ctures for dental practitioners will be delivered at the ental Hospital, Great Charles-street, Birmingham, at P.M. on Thursdays, Nov. 17th and 24th, and Dec. 1st and h. Particulars may be had from the clerk to the Dental oard at the University.

MEDICAL AND VETERINARY CONGRESS IN MOROCCO. congress to be known as Journées Médicales et Vétérinres Marocaines will be held next Easter (April 3rd to 8th) Casablanca and Rabat. Among those who will take part e Prof. Leriche, Prof. Calmette, Dr. Ramon, Prof. Lardenis, Prof. Cruchet, and Prof. Vallée. Particulars may be d from Dr. Lepinay, rue de Marseille, Casablanca.

LONDON SCHOOL OF HYGIENE AND TROPICAL EDICINE.—The following appointments have been made: . Reginald Lovell, M.R.C.V.S., D.V.S.M. Manch., research sistant in comparative pathology; Mrs. M. M. Smith, A., demonstrator in bacteriology; and Miss H. M. Woods, S.S., assistant lecturer in the division of epidemiology and al statistics. Mr. W. Rees Wright, M.Sc., has been pointed to a temporary research post, for the purpose of ntinuing Dr. P. A. Buxton's investigations on the biology stegomyia.

BRITISH ORTHOPÆDIC ASSOCIATION.—On its visit Bath on Oct. 22nd, this Association was entertained to heon in the Guildhall by the mayor, Alderman Cedric ivers, who was himself unable to be present owing to ness. The mayoress, Madame Sarah Grand, said that she shed that all people unconnected with hospitals could see e Orthopædic Hospital at Bath, for to her the cures ected there were among the most marvellous results surgery. After lunch the members of the Association ited this hospital and returned to the Old Baths for the ening ceremony, which was performed by Councillor cker. He said that that day they were celebrating the 0th anniversary of the reconstruction by Sir John Wood nr.), of the King's Bath, which actually dated back to e times of the Saxons. The Hot Bath might certainly be old. In the days of the Normans, Robert of Lewes, the hop of the town (city) built a small lepers' bath adjoining e Hot Bath for the relief of sufferers from the various skin eases which were then rife. That bath was used with rious alterations until 1777, when John Wood, the younger, epared designs for the Corporation for a new hot bath. his report, written 150 years ago, he had said that they uld not but flatter themselves that the Corporation Bath, who had already so eminently distinguished themves in providing that small bath for the use of the public, uld turn their attention to the larger ones, and would think their duty to render the use of the salutary waters as pensive as possible, in gratitude for the blessings of the springs. They had every reason to be proud of the ord of the Baths' Committee within the last few years, the town was meeting foreign competition by becoming re and more attractive, and by increasing in efficiency a place of healing.

WOOLWICH AND DISTRICT WAR MEMORIAL HOSPITAL.—This hospital at Shooter's Hill will be opened by the Duke of York on Wednesday, Nov. 2nd, at 2.45 P.M.

Dr. Abraham Flexner, of the Rockefeller General Education Board, has accepted the invitation of the Vice-Chancellor of the University of Oxford and the Rhodes Trustees to be the Rhodes memorial lecturer for the year 1928.

UNIVERSITY OF LONDON ANIMAL WELFARE SOCIETY. Prof. F. T. G. Hobday will take the chair at a public debate on Humane Slaughtering, to be held at Birkbeck College, Bream's Buildings, E.C. 4, at 8 P.M. on Friday, Nov. 4th. The address of the Society's hon. secretary is 14, The Hawthorns, Finchley, N. 3.

SCARCITY OF DENTISTS.—Mr. W. Malcolm Knott, chairman of the Surgical Committee, presided recently at the distribution of prizes to successful students of Birmingham Dental Hospital and School. He said that the number of students in the school might well be doubled. To make good the losses on the Dental Register, by death and retirement from practice, an annual addition of 625 dental surgeons was needed, whereas the present addition was only 450; this year, indeed, there would be only 380 accessions. In five years' time the scarcity would amount to over 1000 men.

LONDON CLINIC FOR ARTIFICIAL SUNLIGHT TREATMENT.—Under the auspices of the British Humane Association, which was inaugurated in 1923 by Mr. Campbell Johnson, with the object of promoting better health education among the poor in all parts of the world, the London Clinic was opened in Ranelagh-road, Pimlico, London, by Princess Louise, Duchess of Argyll, on Oct. 26th. The new establishment is the outcome of a small clinic held in one room at Tufton-street, the work of which so grew that larger premises became necessary. In addition to sunlight treatment there are rooms for diathermy, massage, and electrical treatment generally, though no provision at present has been made for an X ray instalment. Dr. Edward James Deck is the medical superintendent, and it is intended that the institution should run on lines similar to those of a general hospital, patients being seen by an almoner, in order to prevent abuse of charity.

CHELSEA CLINICAL SOCIETY.—At the annual dinner held on Oct. 25th at the Café Royal, the President, Dr. L. D. Bailey, responding to the health of the Society, proposed by Alderman Jefferson Hogg, said that there were now 150 members, more than half of whom lived outside Chelsea. The Society was in its twenty-ninth year; it was one of the best fraternities in London, and every one of its members was keen. Dr. F. J. McCann, proposing the health of the Kindred Societies, referred to the dinner meetings of the Chelsea Clinical Society and contrasted them with earlier occasions, when it was difficult to induce the weary, worn, and sometimes dinnerless doctor to attend. This was an age of short speeches and short stories, and the main defect of English medical men, as seen at congresses abroad, was their failure to show pictures or objects that would catch their hearers' interest. Mr. Mortimer Woolf, replying as President of the Hunterian Society, said that in preparing a speech the rule was to have ready the first and last sentences, and he wondered whether they ought not to be consecutive. He spoke of John Hunter's relations with St. George's Hospital. Mr. Ivor Back, proposing the health of the Guests, was reminded of George III., who was shown a list of the generals who had been selected to fight Napoleon. "I do not know what effect they would have on Napoleon," said he, "but by God they frighten me." He described a recent interview with an American patient to whom he recommended operation. "Yes, Sir," said the patient, "but there's only one surgeon can operate on me and that is the surgeon who can run faster than I can." Sir William Orpen referred to the number of the guests present and was reminded of a man who ordered 12 poached eggs in the hope that one might be good. Dr. Leonard Huxley, after an amusing analysis of his relations with doctors, spoke of the respect in which they were held by Robert Louis Stevenson and Dr. Johnson. Mr. J. Hugh Edwards, M.P., said that for some reason the public had more faith in doctors than politicians, though he could not understand why. If a Member of Parliament had claimed to have swum the Channel no one would have believed him. He was glad that leading members of the medical profession had ceased to fling chunks of wholemeal bread at one another in the press and had surrendered their pitch to the Bishops. Mr. Alan Hogg spoke of the value of medical work in Africa. Dr. Ernest Young proposed the Health of the President, which was drunk with musical honours, and Dr. Bailey, in turn, proposed the Health of the Officers, to which Dr. Eckenstein responded.

LONDON HOSPITAL DINNER.—The annual dinner of old students was held at the Trocadero Restaurant on Oct. 20th, Dr. Angus Kennedy in the chair. Proposing the health of the hospital, Dr. Kennedy referred to the loyalty which it evoked and the training which it gave; the most enduring friendships of his life had been formed there. When he was a resident 35 years ago conditions had been very different from what they were now; in those days the steak had been so toxic as not to be eatable and no one faced dinner in hospital if he had earned a fee which would pay for it somewhere else. Dr. Russell Andrews complimented Dr. Kennedy on his recent success in catching burglars much younger than himself, and told a number of his receiving-room stories to an audience which always asked for more. After the Chairman's health had been drunk with musical honours, the diners left their tables and the rest of the evening was spent according to temperament. In view of Lord Dawson's recent comments in the House of Lords on the growing sobriety of the younger generation it was interesting to note that the residents were distinctly quieter than last year.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY, Burlington House, Piccadilly, W.
THURSDAY, Nov. 3rd.—4.30 P.M., Prof. Hans Spemann: Organisers in Animal Development (Croonian Lecture).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
TUESDAY, Nov. 1st.—5.30 P.M., ORTHOPÆDICS. (Cases at 4.30 P.M.) Cases: Mr. Alan Todd: Dupuytren's Contracture in a Girl of 15. Mr. Rowley Bristow: Anatomical Variation of the Semilunar Cartilage. Mr. St. J. D. Buxton: Two Cases of Fibrocystic Disease of the Humerus. Other cases will be shown. 8.30 P.M., PATHOLOGY. Laboratory Meeting at the Middlesex Hospital, W. The Library will be open until 10 P.M.
WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. Papers: Mrs. Singer and Mr. R. Steele: The Emerald Tablet of Hermes. Mr. W. Dawson: Mummies as a Drug. Members are invited to bring objects, books, prints, documents, instruments, medals, &c., of historical interest, for exhibition at the meetings of this Section. 8.30 P.M., SURGERY (at the Royal College of Surgeons, Lincoln's Inn-fields). Paper: Sir Arthur Keith: Concerning the Origin and Nature of Osteoblasts.
THURSDAY.—8.15 P.M., TROPICAL DISEASES. Paper: Dr. Aldo Castellani: Blastomycosis Cutis. Other short papers will be read.
FRIDAY.—5 P.M., LARYNGOLOGY. (Cases at 4 P.M.) Cases and specimens will be shown by Sir StClair Thomson, Mr. Bell Tawse, Mr. Vlasto, Mr. Herbert Tilley, Mr. Harold Kisch, Mr. T. B. Layton, Sir James Dundas-Grant, and others. 8.30 P.M., ANÆSTHETICS. Presidential Address: Dr. Cecil Hughes: The Present Position of Spinal Anæsthesia. The Library will be open until 10 P.M.
SATURDAY.—10.30 A.M., OTOLOGY. (Cases at 9.30 A.M.) Presidential Address: Dr. J. S. Fraser: A National Investigation of Otosclerosis. Cases and specimens will be shown by Mr. R. J. Cann (introduced by Mr. T. B. Layton), Mr. Norman Barnett, and others.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Oct. 31st, to SATURDAY, Nov. 5th.—FELLOWSHIP OF MEDICINE. Special lecture at the Medical Society, 11, Chandos-street, Cavendish-square, W., Mon., 5 P.M., Mr. Lawrence Abel: Points in the Diagnosis and Treatment of Pyuria.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Special surgical demonstration by Mr. Bright Banister at 2 P.M. on Mon.—HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. Special medical demonstration by Dr. Donald Paterson at 2.30 P.M. on Mon. (The above are open to the medical profession without fee.)—LONDON LOCK HOSPITAL, Dean-street, W. Comprehensive course for one month; clinical instruction and formal series of lectures.—HAMPSTEAD GENERAL HOSPITAL, Haverstock-hill, N.W. Special course for general practitioners, 4.30 to 6 P.M. —NATIONAL HOSPITAL, Queen-square, W.C. Special post-graduate course in Neurology. Further information from the Secretary, Mayfair 2236.

WEST LONDON HOSPITAL, POST-GRADUATE COLLEGE, Hammersmith, W.
MONDAY, Oct. 31st.—11 A.M., Mr. Tyrrell Gray: Surgical Wards. 2 P.M., Mr. Armour: Operations. 4.30 P.M., Mr. Addison: Tumours of the Breast (lecture).
TUESDAY, Nov. 1st.—10 A.M., Medical Registrar: Ward Demonstration. 2 P.M., Mr. Sinclair: Surgical Out-patients. 4.30 P.M., Dr. Owen: Infant Feeding (lecture).
WEDNESDAY.—10 A.M., Dr. Owen: Medical Diseases of Children. 10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Dr. Ironside: Medical Out-patients. 3 P.M., Sir H. Simson: Gynæcological Ward.
FRIDAY.—10 A.M., Dr. Dowling: Skin Department. 2 P.M. Mr. Tyrrell Gray: Operations. 4.30 P.M., Mr. Sinclair: Gall-stones (lecture).
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy and Ward List. 10 A.M., Dr. Owen: Medical Diseases of Children.
Operations, Medical, Surgical, and Special Out-patient daily 10 A.M. to 5 P.M.; Saturdays, 10 A.M. to 1 P.M.

ROYAL NORTHERN HOSPITAL, Holloway, N.: POST GRADUATE COURSE.
TUESDAY, Nov. 1st.—3.15 P.M., Mr. L. E. Barrington: Ward: Chronic Indigestion Considered Surgically.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
THURSDAY, Nov. 3rd.—4 P.M., Dr. Thursfield: The Grave Forms of Anæmia.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION
WEDNESDAY, Nov. 2nd.—3.30 P.M. (at the Wellcome Bureau of Scientific Research, Endsleigh-gardens, W.C.), Dr. S. H. Daukes: Lecture-Demonstration on Blood Diseases.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Nov. 1st.—5 P.M., Dr. Knowsley Sibley: Principles of Treatment. Local.
THURSDAY.—5 P.M., Dr. A. M. H. Gray: Streptococcic Infections.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Nov. 2nd.—4 P.M., Sir H. Gauvain: Tuberculosis as a Problem of Childhood.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.
TUESDAY, Nov. 1st.—4 P.M., Prof. D. P. D. Wilkie: Gall-Bladder Disease and Gall-Stones. Discussion to be opened by Dr. James Orr.

PEOPLE'S LEAGUE OF HEALTH.
THURSDAY, Nov. 3rd.—6 P.M. (at 11, Chandos-street, Cavendish-square, W.), Dr. J. Sim Wallace: Teeth.

ANCOATS HOSPITAL (Mill-street, Manchester) POST GRADUATE LECTURES.
THURSDAY, Nov. 3rd.—4.15 P.M. (tea at 3.45 P.M.), Dr. Kletz: Diarrhœa.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
FRIDAY, Nov. 4th.—4.15 P.M., Dr. A. D. Macdonald: Shock.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINIC
FRIDAY, Nov. 4th.—3.30 P.M., Dr. Naish: Clinical Cases.

ST. MARY'S HOSPITAL, Whitworth-street, Manchester.
TUESDAY, Nov. 1st.—4.15 P.M. (tea 3.45 P.M.), Dr. H. Cameron: Lloyd Roberts Memorial Lecture: The Child in General Practice. A Study Both in Temperament and Disease.

Appointments.

COOKE, R. HUNT, M.D., M.R.C.P. Lond., has been appointed Honorary Anæsthetist, Hospital for Epilepsy and Paralysis, Maida Vale.

LUMB, N. P. L., M.B. Lond., F.R.C.S. Eng., one of the Medical Referees under the Workmen's Compensation Act, for the Districts of the Bishop's Waltham; Petersfield; Portsmouth; and Newport and Ryde County Courts.

MAINGOT, RODNEY, F.R.C.S. Eng., Visiting Consulting Surgeon, Victoria Hospital, Swindon.

STOESSIGER, HILDA N., M.D., M.R.C.P., Honorary Medical Registrar, Victoria Hospital for Children, Tite-street, Chelsea.

Certifying Surgeons under the Factory and Workshop Act: JAMES, G., L.R.C.P. Lond., M.R.C.S. (Llanelly District of the County of Carmarthen); YOUNG, J. M., M.B., Ch.B. Edin. (Cardenden District of the County of Fife).

Manchester Royal Infirmary: SMILEY, A. G., M.B., Ch.B. Manch., Junior Assistant Resident House Surgeon (central branch); JONES, G. W., M.B., Ch.B. Manch., Resident House Surgeon to the Special Departments; REGAN, N., M.B., Ch.B. Manch., and ARNING, D., M.B., Ch.B. Manch., Clinical Assistants, Medical Out-patient Department; EDWARDS, M. E., M.B., Ch.B. Manch., and BRADLEY, D. M., M.B., Ch.B. Manch., Clinical Assistants, Surgical Out-patient Department; ELL, R., M.B., Ch.B. Man., Cardiological Registrar; ASHWORTH, H. K., M.B., Ch.B. Manch., Junior Anæsthetist.

Westminster Hospital: BALL, W. A., L.R.C.P. Lond., M.R.C.S.; COWLE, G. H., L.R.C.P. Lond., M.R.C.S., House Physician; OLSSON, G. K., L.R.C.P. Lond., M.R.C.S., House Surgeon; SCOTT-EASTON, W. H., L.R.C.P. Lond., M.R.C.S., Resident Obstetric Assistant; CUTTING, P. E. J., L.R.C.P. Lond., M.R.C.S., Resident Medical Officer.

Vacancies.

For further information refer to the advertisement columns.

Birmingham, Witton Babies Hospital.—Res. M.O. £150.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.P. rate of £120.

ournemouth County Borough.—M.O.H. and Sch. M.O. £1000.
urton-on-Trent, Bretby Hall Orthopædic Hospital.—Res. M.O. £450.
uxton, Devonshire Hospital.—Bacteriologist. £400.
iro, Egypt, Girl's Schools under the Ministry of Education.—Asst. Med. Inspector. L.E.480.
nterbury, Borough Mental Hospital.—Asst. M.O. £350.
rdiff, Glan Ely Tuberculosis Hospital, Fairwater.—Jun. Asst. M.O. At rate of £200.
rdiff University College of South Wales and Monmouthshire.—Professor of Pathology and Bacteriology. £1500.

ffield Royal Infirmary.—Hon. Asst. Surg. in Ear, Nose and Throat Dept.
nsea Hospital.—H.S. to Ophth. and Aural Depts. £150–£200
iversity College Hospital, Gower-street, W.C.—Asst. Radiologist. £200.
st Middlesex Hospital, Isleworth.—Asst. to Med. Supt. £250.
rlesden, General Hospital, Harlesden-road, N.W.—P. in charge of Dept. for Dis. of Skin.

Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment for a Certifying Factory Surgeon at Deal (Kent).

Births, Marriages, and Deaths.

BIRTHS.

ES.—On Oct. 15th, at Thorne House, St. Albans, the wife of Dr. Kenneth Bates, of a daughter.
DLEY.—On Oct. 20th, the wife of Dr. W. H. Bradley, Stratton-on-the-Fosse, of a son.
RELL.—On Oct. 19th, at Melville-street, Ryde, I.W., the wife of A. Ambrose Burrell, M.B., of a daughter.
NES.—On Oct. 19th, the wife of Geoffrey Keynes, F.R.C.S., of Boundary-road, N.W., and Park-square West, N.W., of a son.
MSON.—On Oct. 16th, at Musgrave Hall, the wife of Dr. Hugh Thomson, of a son.

MARRIAGES.

MACK—LIDDLE.—On Oct. 18th, at St. Columba's, Pont-street, London, John Godfrey Cormack, M.B., son of Mr. John Cormack, Publisher, Edinburgh, to Eleanor Margaret, only daughter of Mr. A. Liddle, Penrith.
TON—EADS.—On Oct. 15th, at Holy Trinity, Hazlemere, Bucks, James Ernest Horton, L.D.S.R.C.S. Eng., to Dorothy Margaret, elder daughter of Mr. W. J. R. Eads, of Luton.

DEATHS.

MS.—On Oct. 16th, aged 40 years, David Rutherford Adams, M.D. Glasg., of Linden Lodge, Torquay.
RN.—On Oct. 18th, Andrew Russell Bearn, M.D., F.R.C.S., in his 41st year.
SON.—On Oct. 23rd, at Clifden House, Twickenham, John Rudd Leeson, M.D., J.P., F.L.S., F.R.A.S., Mayor of Twickenham, in his 74th year.
T.—At a nursing home, Glasgow, on Oct. 19th, 1927, William McNiven Muat, C.B.E., M.B., C.M., of 14, Hamilton Park-terrace, Glasgow, late Senior Medical Officer, Weihai-wei, North China, beloved husband of Elsie Hurst. No flowers by request.
ET.—On Oct. 17th, after an operation, Peter Paget, Colonel A.M.S., T.A., T.D., of Gloucester-terrace, W., aged 62.

—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Comments, and Abstracts.

CRICKET AND ITS RELATION TO THE DURATION OF LIFE.

BY A. BRADFORD HILL, PH.D.

(*From the National Institute for Medical Research, London.*)

THERE is a common belief that first-class athletes, in spite of their physique, are not "good lives"; that they tend to exhaust themselves by the physical efforts they make and to die relatively young either from a "weakened heart" or from phthisis. Yet, on the other hand, such a class must form an extremely "select" population, selected for physical stamina and powers of endurance. For this reason the obvious expectation would be that they were "lives" *above* the average. The explanation of the apparent paradox probably lies in the emphasis that is placed by the mind upon the tragedy of early death. The perspective is wrong. The exceptions are observed and remembered; they are not related to the general rule. Or, again, the strain which first-class athletes undergo is observed, but it is considered in relation to *average* physique and not in relation, as it should be, to the exceptional physique these persons possess.

Occasionally data exist which will allow a scientific analysis to be made in support or denial of general belief. For instance, in the case of first-class cricketers "Wisden's Cricketers' Almanac" devotes one section to biographical details. Information—i.e., year of birth and year of death—can be extracted which will enable us to see whether this class of athletes actually is short-lived or not.

For the purposes of this study the 1926 issue was used and account was taken of all cricketers (of British nationality) who were born not later than 1888 and had played for any English county or for either Oxford or Cambridge University. The end of the experience was taken as 1913 so as to exclude the war years, and all those who were still alive at the end of that year were then treated as "exits," by the ordinary life-table method. The number born before the nineteenth century was too small to be of service, and excluding these there remained 3424 first-class cricketers born between 1800 and 1888. These were divided into two sections: (1) those born between 1800 and 1849, and (2) those born between 1850 and 1888. A life-table was drawn up for each group. The former can be compared with English Life-Table No. 4, which is based upon the mortality of 1871–80, or, in other words, since the rates of mortality were calculated from age 25 to age 80, upon births between 1791 and 1855. The latter group of cricketers—i.e., births between 1850 and 1888—coincides closely with English Life-Table No. 8, which is based upon the mortality of 1910–12, or, since the rates of mortality were calculated from age 25 to age 60, upon births between 1850 and 1887. These comparisons are set out in Table I.

TABLE I.—*Comparison of Cricketers with General Male Population.*

—	Cricketers born between 1800 and 1849.		English Life Table No. 4. Males. Births between 1791 and 1855.	Cricketers born between 1850 and 1888.		English Life Table No. 8. Males. Births between 1850 and 1887.
